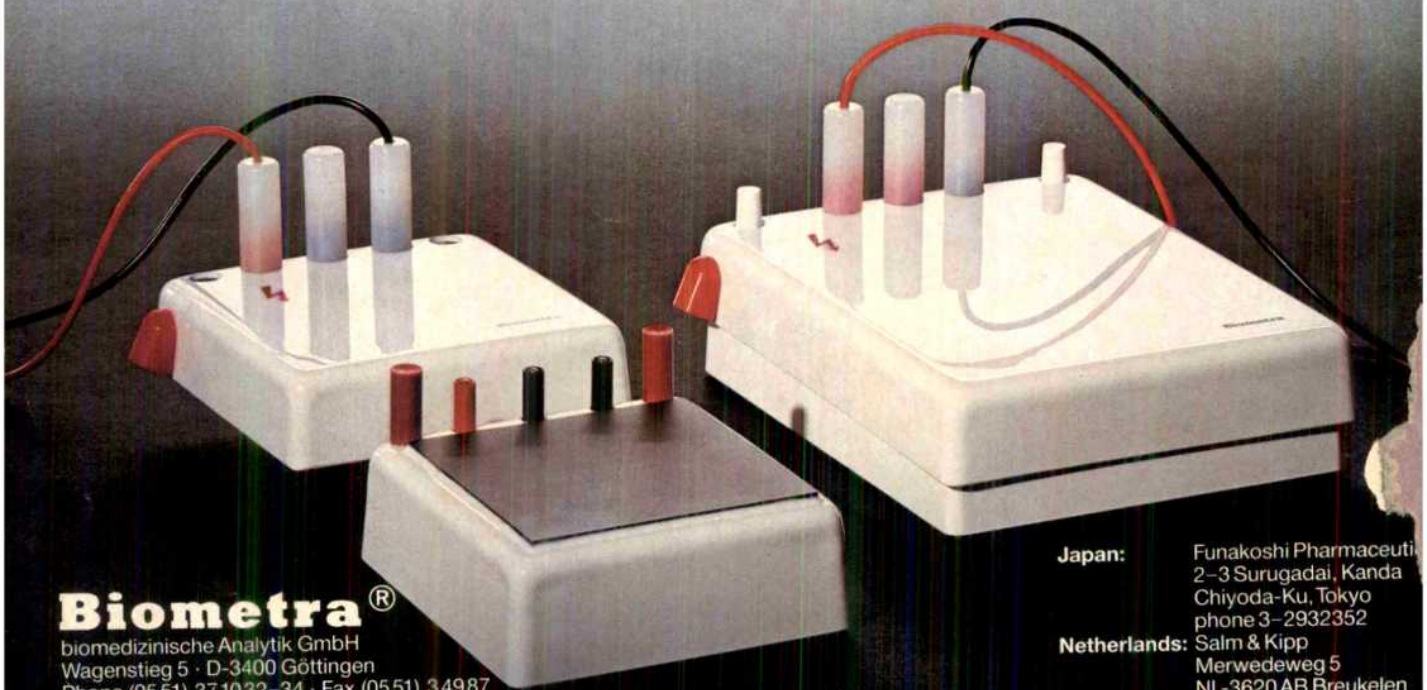
NESTED SUPERNOVAE

BLOTTING IN MINUTES



⇒ New electrode material with higher resistance against oxidative distruction than ordinary carbon

⇒ Now high currents can be applied (up to 5mAmp/cm²)

⇒ Acceleration of the blotting process into time scale of 5–20 min.

Biometra® FAST-BLOT®

● electrode sizes 16×20 cm and 12×12 cm ● water cooling system

SDS-PAGE, 2-D electrophoresis, blotting, and electro-elution. All in the same cell.

Every mini cell is fast; only one is versatile.

SDS-PAGE electrophoresis is completed in only 40 minutes. The Mini-PROTEAN™ II cell's leakproof casting system and snap-on clamp assemblies simplify set-up procedures for running SDS-PAGE gels. Its capacity for up to 30 samples makes it ideal for rapid screening applications.

Electrophoretic blotting of two mini-gels can be completed in one hour. Minimum buffer requirements and a self contained cooling system are two advantages of this rapid miniature blotting cell.

IEF tube gels for 2-D are finished in 90 minutes. High resolution 2-D analysis, including silver staining, is completed in half a day.

Preparative recovery of nucleic acids and proteins is easily accomplished with the Model 422 Electro-Eluter. Patented Membrane Caps with self contained dialysis membranes simplify assembly and insure leak-proof sample collection with ≥ 80% sample recovery. Available as a stand-alone unit or as a module for the Mini-PROTEAN II cell.

All you need is one cell — the Mini-PROTEAN II SDS-PAGE electrophoresis cell. Three different modules are available to transform this popular cell into a mini-tube cell, a Mini Trans-Blot™ cell, or an electro-eluter.

Just remove one module and drop in another. It's that easy. Each module is also available with its own buffer tank and lid, which will make it a stand-alone instrument.

No other mini electrophoresis system offers such convenience and versatility. More than that, you'll economize on reagents, speed up your runs, and save substantially by not having to buy extra equipment as your electrophoresis applications expand.

For details on this innovative approach to mini electrophoresis, contact us and ask for Bulletin 1273.

It's the quality that counts

Introducing the Pharmacia LKB RediFrac. The simple, stand-alone fraction collector for Standard Chromatography.

Buying an ordinary low cost fraction collector can be kind to your budget but hard on your results – and your peace of mind. You need to be able to trust the quality of your fraction collector even the most simple. This quality can cost a little more, but always pays in the end.

Why take the risk? Trust the RediFrac, the latest of the top quality fraction collectors from Pharmacia LKB. Every drop collected every time. Always working, always secure, year after year. Count on our quality and buy the best.
Buy RediFrac.

- High quality gives trouble-free collection
- Small and lightweight, goes anywhere you want it
- Simple to use for a fast start to separations
- Safe collection of every drop in every tube
- Tough and resistant against cold, chemicals and humidity
- Essential extras – range of racks, cooling, event mark and pump control

RediFrac – now the best choice for simple fraction collection.

High performance Hybond™ membranes

Amersham's popular range of Hybond membranes are available in a wide variety of shapes and sizes for use in all your nucleic acid and protein blotting applications. Each pack comes with a comprehensive step-by-step protocol to help you achieve the best results.

Hybond products available are:

- Hybond-N (nylon) — Ideal for nucleic acid blotting, this strong nylon membrane shows high sensitivities in Southern and Northern blotting, even after many reprobings. UV cross-linking allows covalent bonding of nucleic acid sample to the membrane in just 2-5 minutes.

HYBOND-N+ NEW HYBOND-N+

- Hybond-N+ (positively charged nylon) — New to the Hybond range, this membrane requires no oven baking or UV fixation, making it easier to use. Hybond-N+ gives higher sensitivities in nucleic acid blotting than those normally obtained using conventional nylon membranes.
- Hybond-C (nitrocellulose) — A high quality nitrocellulose membrane that is ideal for use in protein blotting, giving high resolution and sensitivity.
- Hybond-C extra (supported nitrocellulose) — A hard-wearing membrane, which exhibits all the binding characteristics of nitrocellulose with the physical strength of nylon, making reprobing easy.

For further information contact your local Amersham office.

nature

5 January 1989

Vol. 337 Issue no. 6202

Filaments within the supernova remnant Puppis A have diverse chemistry, composed primarily of nitrogen (shown red), oxygen (blue), and sulphur (green). These elements, synthesized inside massive stars, may be debris from a second supernova which exploded nearby. See page 48.

THIS WEEK

Seeing the unseen

Can Earth-like planets orbiting other stars be detected? Aperture synthesis could be used to image distant planetary systems at submillimetre wavelengths, page 51. Submillimetre observations are already bringing about a revolution in our view of the Universe, page 15.

Vaccine for seals

Seals can be protected from phocine distemper by vaccination with certain inactivated canine distemper virus vaccines. See page 21.

Molecular chaperones

The *Escherichia coli* heat-shock proteins GroEL and GroES are necessary for the assembly of prokaryotic Rubisco synthesized from a gene introduced into the bacterium, confirming the idea of 'chaperonins' as a general device for assisting the assembly of complex molecules, page 44.

Venusian volcanism

Venus's clouds of sulphuric acid, constantly replenished by volcanic eruptions and depleted by reactions with the planet's surface, will disappear in about two million years if the volcanism moderates. The geochemically estimated rate of volcanism of 1 km^3 per year, lower than two geophysical estimates, can just sustain the clouds, page 55.

Eye of the tiger beetle

A species of tiger beetle uses pointillistic mixing of colours (as in impressionist painting) to produce a cryptic colour pattern, page 72.

Anniversaries for 1989

Mary Evans

The Natural History of Selborne by Gilbert White (here shown aggravating the local fauna) was first published 200 years ago. An anniversarial cornucopia is to be found on page 29.

Modulating behaviour

This week's Review Article considers the part played by neuromodulation in selecting and coordinating coherent behaviours, which can be investigated at the cellular level in arthropod nervous systems, page 33.

Mass extinctions

Substantial changes in carbon partitioning among sedimentary reservoirs accompanied the mass extinctions that mark the start and end of the Mesozoic era (250 and 66 million years ago), but each event has a distinctive geochemical and isotope signature, pages 39, 61, 64 and News and Views.

Moving out

Female social mammals which disperse from their natal groups often do so to avoid interbreeding with their fathers or other close relatives, page 70.

RIGGS

You can't afford to leave the quality of your biochemicals to chance.

Consider BDH.

We make a wide range of reagents, routinely used in your biochemical work.

We make them to exacting standards of purity – which guarantees you predictable results, time after time.

We make them at a very reasonable price, too.

Which has naturally made our biochemicals leaders when it comes to purity.

BDH are a major name, and a major supplier of biochemical reagents.

Our fame – and our reputation for quality – are spreading.

So it's a rare person indeed who hasn't heard of us.

Rarer still is the person who doesn't order his biochemical reagents from us.

For truly predictable results, call BDH.

Olympus autofocus photomicrography takes the error out of focusing

What the naked eye perceives as sharp and clear often translates into a blurred image on film or paper.

Now Olympus brings you the Vanox-S—the world's first autofocus photomicroscope system—designed to eliminate focusing error in low magnification photomicrography (objectives from 1X to 10X), and ensure needle-sharp imagery throughout the entire magnification range. All you have to do is push the AF button.

And the Vanox-S also enables the use of two 35mm cameras and a large-format camera, incorporated into the body, together with automatic exposure and four photo eyepieces. Light intensity is adjusted with neutral density filters, maintaining color temperature consistency.

The new Vanox-S research photomicroscope system lets you reproduce the actual image you see accurately and with high quality. More easily and consistently than ever before.

Metastic Spread of Cancer

G.V. Sherbet

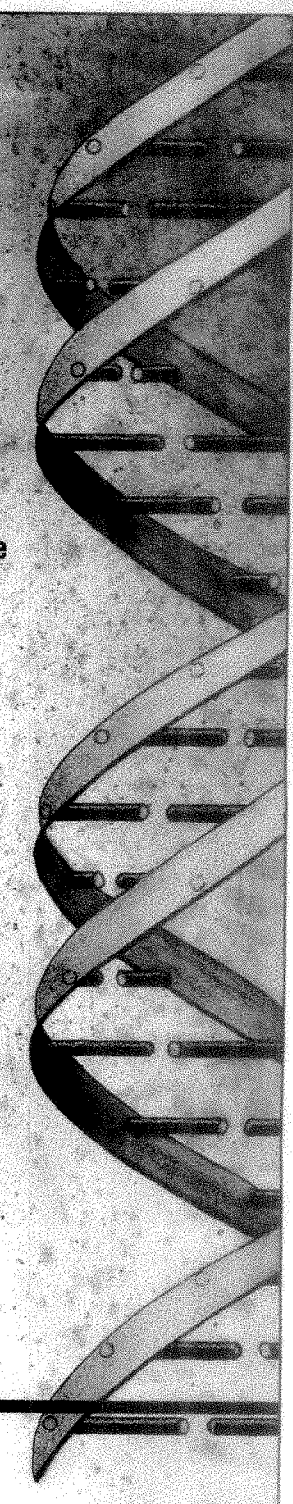
This book outlines a new approach to the analysis of the mechanisms of metastasis by comparing the glioma, an intracranial tumour which ordinarily does not metastasize, to other metastasizing tumour models. This has produced a coherent picture of the operation of oncogenes and growth factors in the initiation, development and progression of neoplasms.

This is an essential book for those researching metastasis and will be of interest to all research oncologists.

1987 **£45.00** 275pp

234x156mm 0 333 443 624

Contents



Part 1
Introduction
The Intrinsic Malignancy of Gliomas
The Metastatic Cascade

Part 2
Heterogeneity of Tumours
Oncogenes in Tumour Development and Metastasis
The Genetic Instability of Neoplasms
The Generation of the Metastatic Phenotype

For Custom Oligonucleotide Synthesis . . . the Choice is Promega.

Introducing Promega's custom oligonucleotide synthesis—another high quality service from Promega's Custom Services Division.

- **CHOICE** Promega will synthesize any oligonucleotide to your specifications on a small (0.25 μmole), medium (1μmole), or large (10μmole) scale. Custom oligos are available either purified or unpurified, containing your choice of 5′ hydroxyl, trityl, or phosphate groups. There is no extra charge for including dI, dU, or dC^{me} in your sequence.
- **QUALITY** Promega's purified custom oligos are suitable for direct enzymatic reactions such as phosphorylation, ligation, and primer extension. Purification is by gel electrophoresis or HPLC. An electrophoretic analysis is provided with each custom sequence (purified).
- **EXPERTISE** Our experience in oligonucleotide synthesis can save your valuable time and resources. Promega's scientists are available to confidentially discuss any questions related to your specific needs.
- **SERVICE** We will deliver unpurified oligos within 2 days and purified product within 4 days of receiving your order. Telephone orders are accepted and verified with audio recordings.

The New Horizon

Hyatt Regency/University of Miami
James L. Knight International Center
Miami, Florida • February 6–10, 1989

The 21st Miami Winter Symposium is the one conference of 1989 that will prepare researchers (both academic and industrial) for the life-science revolution of the 21st century—the human mind's discovery of itself. Don't miss that opportunity. Don't miss *Advances in Gene Technology: Molecular Neurobiology and Neuropharmacology*.

The Symposium offers an unparalleled program. No other gathering offers so many opportunities with such immediate access to fellow attendees. with this six-fold opportunity:

Advances in Gene Technology: Molecular Neurobiology and Neuropharmacology. Five days of lectures, more than 40 top researchers on the molecular biology of the nervous system.

The Second Annual Neural Systems Symposium: Computer Neural Networks. Two days of seminars on modern thinking on neural systems.

Focus Groups. Posters and extracurricular discussions spotlight key research issues from Alzheimer's disease to nerve-cell culture.

Workshops. Hands-on introductions to the latest research tools and concepts.

Placement Service. Job-seekers and employers will meet to fill positions in academia and industry.

Poster Sessions. A hundred authors on hand to present their most interesting results.

NEUROBIOT

ADVANCES IN GENE TECHNOLOGY: MOLECULAR NEUROBIOLOGY AND NEUROPHARMACOLOGY

Monday AM
Molecular Biology of Receptors
J.P. Changeux, K.L. Magleby, J.W. Patrick

Monday PM
The Lynen Lecture
I. Neher and B. Sakmann

Monday PM
Molecular Biology of Ion Channels
W.A. Catterall, D.M. Fambrough, Y.N. Jan

Monday PM
Receptor-Based Diagnostics
S.J. Enna, C.D. Johnson, J. Ramachandran

Tuesday AM
The Distinguished Service Award
W. Gilbert

Tuesday AM
Regulation of Gene Expression
M.G. Rosenfeld, R.H. Scheller

Tuesday AM
Design of Receptor Ligand Pharmacophors
M.B. Bolger, A.D. Strosberg, H.I. Yamamura

Tuesday PM
Cell Recognition and Development
J. Bixby, U.J. McMahan, M. Schachner

Tuesday PM
Nerve Growth Regeneration and Transplantation
A.J. Aguayo, F.H. Gage, F.F. Hefti, J.R. Sladek

Wednesday AM
Molecular Basis of Memory and Learning
D. Alkon, W. Gispen, P. Andersen

Thursday AM
Special Achievement Award
Osamu Hayaishi

Sorting and Localization of Proteins
G.A. Banker, R.B. Kelly, R.L. Rotundo

Thursday AM
Neuropeptides
F.E. Bloom, L.L. Iversen, S.J. Watson

Thursday PM
Second Messengers
K.J. Catt, R. Llinas, H. Rasmussen

Thursday PM
Sensory Systems and Transduction
A.J. Hudspeth, S.H. Snyder, C. Zuker

Friday AM
Molecular Aspects of Neurological Diseases
H.F. Epstein, J.B. Martin, D.L. Price, D.S. Gerhard

THE SECOND ANNUAL NEURAL SYSTEMS SYMPOSIUM: COMPUTER NEURAL NETWORKS: A CRITICAL OVERVIEW

Tuesday
Pattern Recognition as Motivating Neural System Research
David Bendel Hertz

Neural Self Organization
Stephen Grossberg

A Neural Network Architecture For Preattentive Vision
Ennio Mingolla

Adaptive Hand-Eye Coordination
Michael Kuperstein

Optical Realization of Pattern Recognition
Dana Anderson

Stochastic Neural Net and Optical Learning Machines
Nabit Farhat

Neural Networks for Speech Recognition
Richard Lippmann

Wednesday
Instantiation Schemes for Pattern Recognition
Yi-Tzu C. Chien

Optical Realizations of Bidirectional Associative Memories
B. Keith Jenkins

Mapping Multi-Layered Neural Networks for Pattern Recognition Onto Multi-Processors
Genevieve Cerf

Available Recognition Schema
Leon Cooper

Future Directions For Neural Networks
Luis Glaser

The Miami Bio/Technology Winter Symposium wishes to acknowledge the support of its major corporate sponsors: Boehringer Mannheim; Cancer Research Council; The Daniel Heumann Fund for Spinal Cord Research; E.I. duPont de Nemours & Company; Elsevier Science Publishers; GIBCO/BRL; The Kent Waldrep National Paralysis Foundation; The Paralyzed Veterans of America, Spinal Cord Research Foundation; Neurosciences Research Branch of the National Institute of Mental Health; The National Parkinson Foundation; The National Spinal Cord Injury Association; MilliGen/Biosearch, Division of Millipore; Porton Instruments; The Upjohn Company; as well as the University of Miami Office of Research and Graduate Studies.

Conference Registration
WINTER SYMPOSIUM
THE MIAMI BIO/TECHNOLOGY
Miami, Florida
February 6–10, 1989

Please hold these registrations in the name of:
Print

First Last
CIRCLE ONE: MD, Ph.D., D.Sc., Mr., Ms.

Department

Organization or Institution

Street/P.O. Box/Mail Stop

City, State or Province, ZIP or Postal Code

Country

Area Code/Telephone

I understand that as a paid conference participant, I may attend all sessions and receive all program materials.
I would like to attend THE MIAMI BIO/TECHNOLOGY WINTER SYMPOSIUM, February 6–10, 1989.

Student registrants: Please have your mentor sign here.

Associate registrations at $25—associates may not attend scientific sessions, but may attend receptions, go on tours, and take part in the collateral associates' program.

Name of associate

☐ Placement service registrations at
☐ $100 for employers
☐ $10 for employment candidates

Total Registration Fee: $

Payment:
☐ Check enclosed for U.S. $
(U.S. Dollars only)
Please make check payable to: THE MIAMI BIO/TECHNOLOGY WINTER SYMPOSIUM
☐ Please bill my credit card:
☐ American Express ☐ Visa ☐ MasterCard

Credit card number Expiration date

Signature as shown on card

Payment must accompany your registration.

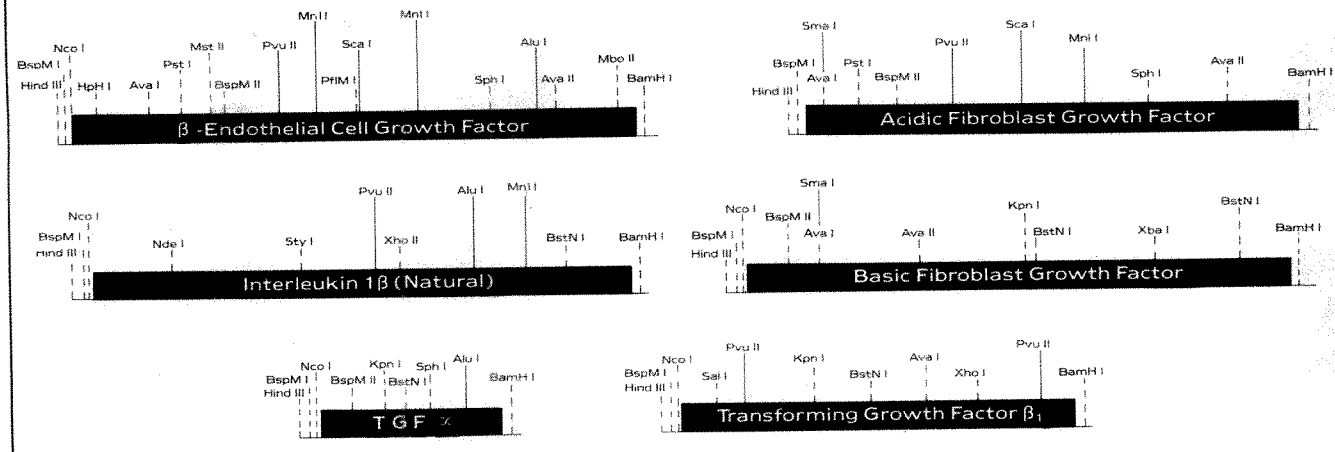
Winter Symposium
P.O. Box 016129
Miami, FL 33101 USA

1-800-MIAGENE
FAX: 1-305-324-5665

Hotel reservations should be made through: M.B.W.S. Housing Office, P.O. Box 016129, Miami, FL 33101, USA, 1-305-547-6244.

Registration fees for both Symposia are:

	MBWS	NSS	Both
Standard	$420 ☐	$270 ☐	$575 ☐
Academic and Government Inst.	$220 ☐	$150 ☐	$300 ☐
Student	$120 ☐	$ 85 ☐	$165 ☐



Cut-off date for pre-registration is January 16, 1989. After this date, registration will only be taken on site.

Sponsor's liability:
Should this conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee.

Cancellation policy:
All cancellations must be received in writing. Cancellations received before December 31 will be subject to a service charge of $25. No refunds will be made after that date. Registrants who are unable to attend may, if they choose, send a substitute.

ECHNOLOGY

6 MORE WAYS TO EXPRESS YOURSELF

Genes also available:

Nerve Growth Factor β
Insulin-like Growth Factor 1
Angiogenin
Interleukin 1 ∝, 2, 3, 4, 5, & 6
GM – CSF
G – CSF
TNF ∝ & β

Genes available soon:

TAT
PDGF ∝
PDGF β
Murine 1L – 7

BBL's range of genes is constantly expanding. Please contact us for further details of our new products and custom synthesis service.

Statistical System - $99

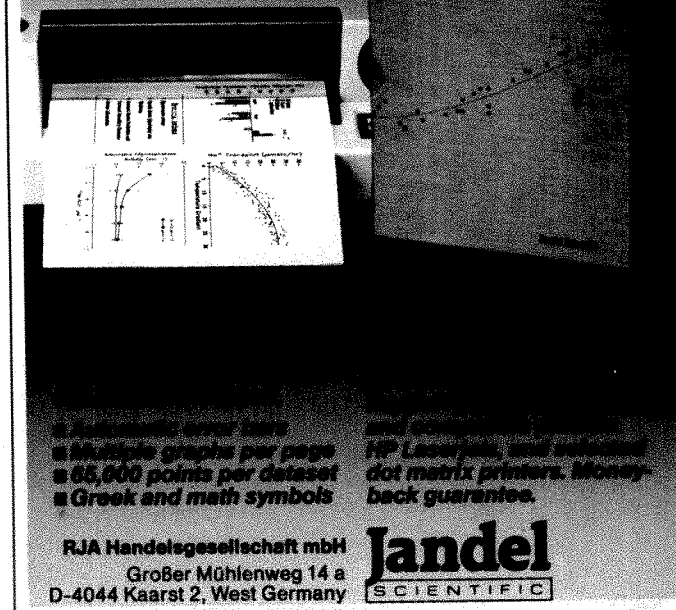
NCSS Series - comprehensive, accurate, easy-to-use (menu-style) MS-DOS system. Spreadsheet data-entry with up to 250 columns and 32,000 rows. Reads ASCII or 123 files. Multiple or Stepwise regression. ANOVA. Repeated Measures. Post-Hoc Tests. Nonparametrics. T-Tests. Descriptive Stats. Factor, Cluster, & Discriminant analysis. Cross-tabulation. Scatter plots. 300 page book. Used by over 5,000 researches, scientists, and students.

NCSS Graphics - $59

Includes scatter plots, box plots, error-bar plots, 3D plots, and much more.

NCSS Power Pack - $49
Includes nonlinear, logistic, and response surface regression. MANOVA. Canonical Correlation matrices.

NCSS Survival Analysis - $59
Product-limit survival analysis, Distributional estimation, Nonparametric tests, Cox Regression, Probit Analysis. Includes survivorship and hazard plots.



VISA/MC Welcome

Jandel SCIENTIFIC

"Microcomputer Tools for the Scientist"

Automated Submicron Particle Size Analysis

COULTER® N4MD

WHEN YOU HAVE ALL THE ANGLES, YOU CAN'T BE MISLED

Your only assurance of complete size distribution

Single 90-degree scattering angle photon correlation spectroscopy (PCS) instruments cannot detect total size distribution. Only the COULTER Model N4MD uses multi-angle fiber optic-based detection to uniquely characterize and accurately measure a wide range of particle sizes (.003 to 3μm), and molecular weights (10^4-10^{13} Daltons), over a wide range of concentrations – automatically.

With speed, accuracy and reproducibility

Only the N4MD features a unique information enhancing Multi-Tau (multiple time base) autocorrelator coupled with an integral size distribution processor (SDP), which is based on CONTIN – the industry standard analysis program.

The result is component resolution of polydisperse samples into discrete subpopulations and a report of their respective proportions – providing more accurate, more reproducible resolution of broad dynamic range samples in a single rapid analysis.

And walk-away automode operation

All you do is push a button. The Model N4MD automatically carries out a preliminary sample scan, selects the appropriate operating parameters, analyzes the sample, changes angles and provides a complete report.

Plus convenient data storage and management

For even greater versatility and consistency, choose the AccuComp® data management and storage software for automated statistical analysis of multiple runs and specialty calculations, such as hollow sphere conversions used in liposome applications.

One number for all the service and support you'll ever need

For complete information about the COULTER N4MD or other Model N4 series submicron particle size analyzers, call the toll-free number below and request extension 2818. And remember, all Coulter instruments are backed by the world's most recognized Customer Service and applications support team. In the U.S., call

(800) 526-6932

Outside the U.S., contact your Coulter representative, or call 305-885-0131.

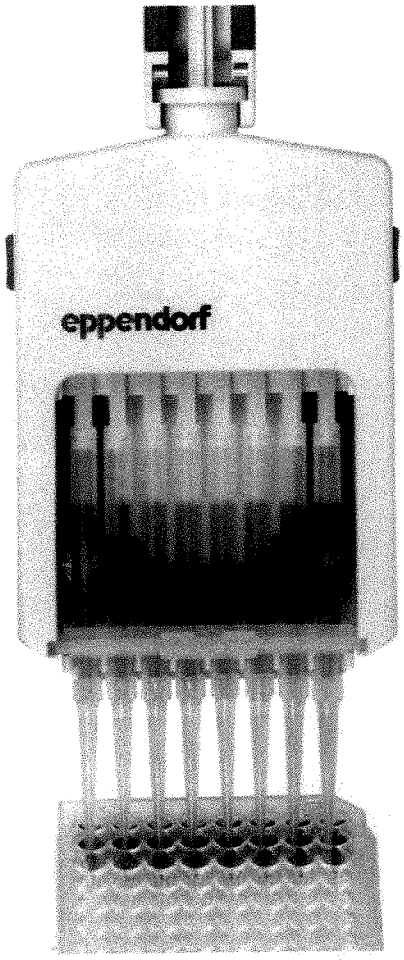
RECOGNIZING YOUR NEEDS ARE MORE THAN INSTRUMENTAL

Eppendorf Plus/8



One more plus for the Multipette®

Dispense 8 times faster with the Plus/8

Plus/8 turns the Eppendorf Multipette into an 8 channel hand dispenser for series dispensing. With this system, you can fill microtiter plates in a flash. Depending on the volume selected, between 25 and 125 µl, you can even fill up to four microtiter plates without having to reload the Plus/8.

Eppendorf Plus/8 - rapid, precise, sterile

Two cartridges designed for different pipette tips are available for the Plus/8. You can also order sterile cartridges.

NATURE VOL. 337 5 JANUARY 1989

Nature's East–West exchange

In the knowledge that the scientific enterprise is genuinely international and in the belief that Mr Mikhail Gorbachev's speech to the United Nations on 3 December offers us all the promise of a different world, Nature *makes the following announcement to and solicitation of its readers.*

WHILE on the face of things there may seem little that the scientific community can do, except to keep on working, to assist or cement the recent transformation of East–West relations, that is not strictly the case.

First, there is ample evidence that the huge Soviet research community, hampered as it is by bureaucracy and shortages of equipment, would benefit from closer relations with the outside world. Individuals might thereby be helped to be more creative. Research laboratories and institutes could well be more productive and effective if their inevitable isolation were abated even modestly. There can be few in the West who would not acknowledge that these benefits must be mutual.

It is also plain that Soviet science has much to offer, even in these competitive times, to people working in the relatively well-equipped laboratories of the West. Those benefits would also be mutual.

In the past few years, public authorities in the Soviet Union and elsewhere have recognized the urgency of these needs. Opportunities for Soviet scientists to travel to the West have been enormously increased, and at the same time liberalized. Travel in the opposite direction has similarly been enlarged. Research collaborations have multiplied, if less quickly. But it is also clear that there is a long way to go before relations between the Soviet research community and those elsewhere are as intimate and constructive as they might be.

Nature therefore intends to take two practical steps to assist these processes.

- First, we shall do more than has been possible so far to draw attention to important trends in Soviet research, largely for the benefit of readers in the West. Talks with the Academy of Sciences of the USSR, as well as with individual scientists, encourage the belief that there is much that can usefully be done.
- Second, *Nature* will create an informal network, to be known as *Nature*'s East–West Exchange, whose chief objective will be to put professional researchers with mutual interests in touch with one another. *Nature* will function as a post-box only, relying primarily on information voluntarily supplied by readers, but will also use its own network of advisers to identify potential respondents to particular enquiries.

It would be rash to guess how well and how generally this arrangement can be made to work, let alone to estimate its importance in the grander scheme of things. But a scheme for exchanging information and easily transportable materials which is entirely independent of government agencies and established academies may have the special value of enabling informal and, with luck, speedy responses to enquiries.

None of this should be taken as diminishing the importance of the bilateral exchange schemes at present operated by national academies and other agencies, or the arrangements for collaborative research involving Soviet scientists and their counterparts elsewhere. It is also a fact that in some fields, high-energy physics or plasma physics for example, Soviet collaboration with others has always been close. An informal private scheme for the exchange of information may nevertheless usefully complement arrangements already in place.

Readers wishing to participate should send in writing their names, addresses, telephone and telefax numbers to one of the editorial offices in London, Munich, Tokyo or Washington. Readers are assured that this information will not be used for any other purpose.

Readers should indicate their interest in the scheme, which may take one or more of the following forms:

- A request for information or assistance, which should be as specific as possible.
- A statement of particular information and assistance that can be conveniently provided, and which is unlikely to be readily available in the East (or West), which should also be specified as fully as possible.
- An offer to help in identifying sources of information and assistance in particular fields of research, which should also be specified with some precision. ("High-energy physics" or "molecular genetics" may invite more requests for help than respondents would wish.)

It is not intended that the scope of the exchange should be limited, but it is expected that enquiries will at the outset be requests for information, perhaps for software developed specifically for basic research, but physical samples (say, DNA probes) may also be suitable for exchange. Respondents should be aware that it is for them, not *Nature*, to comply with whatever national legislation may be in force.

Particular care will be taken to ensure that Soviet scientists at Soviet universities and less well-known research institutes will be able to collaborate.

No charges should ordinarily be made for information or materials supplied under this exchange, although there may be circumstances when two participants agree that costs arising should be paid for.

Nature will publish reports on progress of the scheme at intervals of three months.

A list of people who have endorsed the general objectives of this scheme will be published next week. □

Europe in trouble

The impending trade dispute with the United States will confirm fears about the new Europe.

THE European Community seems well on the way to being an obstruction to international amity. That is the chief lesson that will be learned from the foolish dispute with the United States over the import of beef which was institutionalized last Sunday, the first day of the New Year. The most immediate consequence will be to sour the atmosphere in which some kind of compromise must be hammered out on the future of the international agreements that make the world's free trade an engine of beneficent economic change; after the collapse last December of the Montreal negotiations of an extended basis for the General Agreement on Tariffs and Trade (GATT), it was agreed that the participants have only until April to settle their differences.

But the more distant yet more serious consequences of the dispute will be to confirm the impression that the new Europe is bent on being a selfish and restrictive member of the international community, more concerned with its own interests than with the well-being of the whole world, which is what the critics of the European Community have always feared.

It is especially discreditable that this year's trade dispute should spring from what is represented as a scientific issue. Two years ago, the European Community took the view that beef cattle nurtured with the help of bovine growth hormones would yield beef that endangers the health of those who eat it. There appears to be no factual basis for this supposition, but every reason to suppose that the truth is that beef from cattle grown in such a way is identical with what might be called natural beef.

Certainly the European Commission's directive which, from 1 January, bans the sale of beef whose growth has been assisted by the administration of growth hormones is innocent of an objective test for telling now-tainted beef from that whose sale is to be allowed. Instead, those wishing to import beef into Europe have to obtain a certificate from suppliers elsewhere that their cattle have not been fed growth hormones to help them grow more quickly. And there seems no doubt that the motives for the new restrictions on the sale of beef grown with the help of hormones are simply the commission's wish to make European agriculture less efficient than it could be, and thus a less embarrassing charge on European budgets. Briefly, Europe has decided to ban the sale of beef grown with the help of growth hormones because it does not wish to pay European farmers even more than it does at present for the accumulation of unsaleable stocks of European beef. In a rational world, of course, the remedy would have been much simpler; Europe would have reformed its irrational policy on agriculture instead.

Response

The immediate response of the United States is understandable. With effect from 1 January, retaliatory tariffs will be applied to certain imports of agricultural produce of European origin.

The losers will be of two kinds — consumers in the United States and farmers in the European Community. But there is worse to come. For the European Community now threatens to retaliate against the retaliation instituted by the United States. There is every likelihood that European agriculture ministers, who have many better things to do, will spend their energies in the coming weeks devising lists of agricultural products from the United States to which further restrictions may be applied. The losers, then, will be European consumers, who will have to pay higher prices for goods to which they have become accustomed. But there is every likelihood that mutual retaliati escalate, causing people on both sides of the Atlan become impoverished and creating a climate in which sensible agreements on the future pattern of free trade cannot be reached.

The prospect of a trade war in agricultural produce between Europe and the United States is, sadly, not the only ominous sign of the way in which modern Europe is tending. In the past few months, the European Commission has responded to the pleadings of European manufacturers by deciding unilaterally that Japanese exports of copying machines and electronic printers are too cheap, and has slapped restrictions on them as well. Japan has rightly decided to appeal against these arbitrary decisions, as GATT procedures allow, but that is a time-consuming and expensive business whose outcome must be uncertain.

Before that corrosive issue can be settled, there will no doubt be other European manufacturers pleading successfully for protection from imports from elsewhere which they consider are too cheap, meaning simply that the prices at which goods are offered for sale are inconveniently and unprofitably low. It may not be long before the manufacturers of civil aircraft, or computing machinery, lodge successful claims that they, too, should be protected from competition from elsewhere. While, in the short run, European manufacturers may enjoy the benefits of markets in which they are the sole suppliers, Europe as a whole will lose both the benefits of competitive prices and of underlying advanced technology.

Gloomy outlook

The outlook is all the more gloomy because the United States, the most likely target of European protectionism, is now equipped with domestic trade legislation that makes retaliation almost a statutory requirement. While the Reagan administration has steadfastly, over eight years, resisted attempts by the US Congress to protect particular industries from competition from elsewhere, it was forced last year to concede a provision that industries with cause to believe that their competitiveness in export markets is thwarted by foreign restrictions should have a right to demand retaliation. Already there is an awesome queue of claimants. It will be especially difficult for a new administration, needing to plead with Congress on the federal deficit, to keep these domestic demands at bay. In short, there is a serious prospect that the attempt to negotiate a new basis for an extension of GATT's terms of reference will be aborted by a trans-Atlantic trade war extending well beyond the field of agriculture.

If that is what happens in the months ahead, Europe will have to bear the chief responsibility. But, sadly, Europe is not a single entity, but rather a collection of twelve governments with different interests, most of which are narrow interests. Decisions made in Brussels by the European Commission ultimately reflect the way in which particular governments are able successfully to plead their own causes. That is the reason why the common market fully specified by the Treaty of Rome has not yet come about — and why there remain serious dangers that the creation of the single market now planned for 1992 may itself be aborted by strategems not yet conceived. The same narrow view of European affairs offers an explanation as to why it has been so difficult to move towards a rationalization of the agricultural policies that are Europe's self-inflicted burden.

The next few years unfortunately offer narrow-minded European governments too much opportunity for insisting that further moves towards internal free trade must be accompanied by economic protection from outside competition. The ironical result of that will be a Europe which will be self-contained and inward-looking — one in which Europe's founding fathers would prefer not to live. □

International expedition studies Arctic ozone

- Differences in Arctic and Antarctic depletions
- Specially designed aircraft to be used

Washington

An international expedition to study stratospheric ozone concentrations in the Arctic begins this week in Stavanger, Norway. Led by the United States, the six-week expedition will employ balloons, satellites, high-altitude aircraft and an international data network to obtain a clearer picture of how Arctic ozone concentrations are affected by the unique conditions at the pole.

Arctic stratospheric ozone concentration exhibits some seasonal variation, but nothing like the severe declines observed over Antarctica. Nevertheless there are indications that similar processes are at work in the Arctic stratosphere, leading to a measurable depletion of ozone. More puzzling, according to Daniel Albritton of the National Oceanic and Atmospheric Administration (NOAA) Aeronomy Laboratory in Boulder, Colorado, is a discrepancy between observed ozone depletion and predicted levels based on models that account for Antarctic depletions, suggesting that some other mechanism is at work in the Arctic.

Two specially designed aircraft will be used to collect data on gas concentrations in the stratosphere. A National Aeronautics and Space Administration (NASA) ER-2 aircraft, a modified U2 reconnaissance aircraft, will carry instruments as high as 20 km for seven-hour flights up to 80 degrees North. A DC-8 will operate during the same period, its greater range allowing it to survey the polar vortex. NASA's Robert Watson, chief program officer for the expedition, says that ozone measurements from the Nimbus 7 satellite will help to develop flight plans for the aircraft.

Of particular interest is how chlorine compounds — primarily from chlorofluorocarbons — react with ice crystals in polar stratospheric clouds to form free chlorine which destroys ozone. Because the Arctic is on average warmer than the Antarctic, there are far fewer of these ice-containing clouds. Albritton says this may partly explain why the decrease in stratospheric ozone is not nearly as large as in the south. Albritton is hoping for a cold polar winter so there will lots of polar stratospheric clouds to test the ice crystal hypothesis.

NASA, NOAA and the National Science Foundation together are contributing some $10 million to the expedition. Additional support, comes from Norway, the United Kingdom, West Germany and the Soviet Union. **Joseph Palca**

Computer smugglers too quick

Washington

Last week's arrest in Miami of a Dutch man accused of attempting to smuggle a Vax 8800 computer to Bulgaria highlights the difficulties the United States is experiencing in stopping advanced computer technology from reaching eastern-bloc countries. The difficulties will get worse, according to a new report* on export controls and computer technology released this week by the US National Research Council, as computers become ever smaller and more powerful and international computer networks flourish.

The nations of the Coordinating Committee for Multilateral Export Control (CoCom) have managed to maintain a five-to-ten-year lead in computer technology over the USSR and eastern-bloc countries, claims the report, but far more "focused and flexible" controls will be needed in the future. The biggest problem is that "computer technologies advance much faster than most bureaucratic processes".

A clumsy bureaucracy will end up stifling industry if it does not distinguish between products that can be controlled and those that cannot — such as computers available from foreign sources and computers that are so cheap or small that their trade cannot be effectively halted. "More timely, rapid and expert" reviews are the answer, according to the report.

To help stop the industrializing Asian nations of Singapore, Hong Kong, Taiwan and South Korea from supplying their own increasingly sophisticated hardware to the eastern bloc, the report urges their integration into the CoCom programme.

The rapid development of computer networks has provided an easy conduit for the export of software. The report calls for "further study" to control transborder flow via computer networks.

Software is intrinsically difficult to protect and most should be freely traded, according to the report, with tight controls reserved for military software and for software tools that could help create military software. **Alun Anderson**

**Global Trends in Computer Technology and Their Impact on Export Control*, published by the National Academy Press, 30 December 1988.

Ecologist murdered

Washington

Last week's murder of the prominent Brazilian environmentalist and union organizer, Francisco Mendes Filho, at his home in Xapuri, in Acre province, is expected to increase pressure on the World Bank and Inter-American Development Bank to demand environmental safeguards before they lend money for large-scale development projects. Through his efforts to organize and protect poor rubber-tapping families Mendes, 44, inadvertently found himself allied with ecologists who wanted to stop the destruction of the rain forest for cattle ranching. His murder, allegedly at the hands of local land barons, has provoked an international outcry and a campaign in Brazil to stop foreign loans until justice has been done. Last year, Mendes received the Global 500 award from the United Nations for his efforts to save the rain forest. A.A.

Shuttle complacency

Washington

Although the US space shuttle has successfully resumed flights, the final report of a special National Research Council panel evaluating the redesign of the shuttle's solid rocket booster concludes that there are still problems with the booster.

In addition to specific, minor problems that cropped up on the two recent shuttle flights, the final report, transmitted in a 21 December letter from panel chairman H. Guyford Stever to National Aeronautics and Space Administration head James Fletcher, suggests there is still work to be done. The report warns that budget, time and complacency will push NASA towards a relaxation of quality control. Although the "relaxation" may be justified, the report urges that it be a planned, deliberate process, and calls for continuous system performance checks to establish a data base against which the shuttle's future performance can be judged. J.P.

Animals' legal rights

Washington

A group of animal rights organizations, led by the Animal Legal Defense Fund, has filed suit against three US government agencies. The group is accusing the Department of Agriculture (USDA), the Department of Health and Human Services, and the Office of Management and Budget of "unreasonably delaying" the establishment of regulations to protect animals used in research which were stipulated by the 1985 amendments to the Animal Welfare Act. The amendments would require researchers to anaesthetize animals subjected to pain, and to provide dogs and primates with living environments conducive to their well-being. The USDA says it is still sifting through the roughly 8,000 comments it has received. C.E.

'Virus-proof' computer security system

Boston

CAN computer operating be made safe from invading viruses, worms and determined hackers? Two computer scientists think the answer is "yes", and they have developed a computer security system which they claim is invulnerable to computer viruses such as the one that recently struck networks across the country (see *Nature* **336**, 97 and 301; 10 and 24 November 1988).

The system, designed by Michael Rabin, a computer scientist at Harvard University, and his former student Douglas Tygar, now assistant professor in the School of Computer Science at Carnegie-Mellon University, is an adaptable set of programs designed to regulate access to information on computer systems.

The system, called ITOSS (Integrated Toolkit for Operating System Security), is the culmination of a four-year effort by Rabin and Tygar. Among its features is a battery of built-in 'sentinels' which can be employed either to warn away users from high-security data, or to record every access to sensitive data files without users' knowledge. A 'fingerprinting' algorithm can also alert system operators to any changes made to programs on the system. Included in the program's design are a 'minimum security' protection for all files against 'trojan horse' programs that might come into the system illicitly, hidden in innocuous messages, and a 'maximum security' feature which requires a specified number of system operators each to input commands in order to make any far-reaching changes in the system.

New systems to protect computers are likely to be necessary if computer operators are to gain the upper hand over hackers. Last month, officials at Lawrence Livermore Laboratory gave up their battle with a hacker who had repeatedly infiltrated low-level security files on the laboratory's computer system. Instead, they left an invitation for the hacker to make direct contact with the laboratory's computer security manager. The hacker accepted the invitation and has now promised to stop his attacks. An FBI investigation is nevertheless under way.

Increase for West German ocean research

Munich

A SIZEABLE increase in support for ocean and polar research in West Germany was recommended last week by the influential Wissenschaftsrat, an independent science advisory board. The board recommended that an additional DM240 million should be spent over the next few years, with the money to come from both the federal and *Länder* governments.

The largest new investment recommended is for a DM75 million research centre in Hamburg which would bring together researchers from the University of Hamburg, the Max Planck Institute for Meteorology, the German Climate Computing Centre and the Federal Biological Research Establishment at Heligoland.

Research should be concentrated, the board says, on interactions between ocean and atmosphere as well as on the study of structure and function of marine ecosystems. The four institutions involved, which are funded out of as many different purses, would have to agree on how to carry out such an integration. Two new institutes are recommended for the Oldenburg/Wilhelmshaven area, one to study the chemistry and biology of the ocean and the other to study coastal wetlands. Together they would cost DM40 million.

The Wissenschaftsrat also praised the Alfred Wegener Institute for Polar and Ocean Research in its first eight years as a *Grossforschungseinrichtung* (large research establishment). The leader of the Bremen institute, Gotthilf Hempel, wants to broaden its focus to include Arctic as well as Antarctic research and to include even more international cooperation. Hempel is chairman of the Arctic Ocean Sciences Board.

Steven Dickman

£520 million plans for UK science park

London

EVERY British university is trying to broaden its funding base and to forge links with industry. With that aim, a business park with a science centre at its core is planned for a 500-acre site near the University of Bristol. Details of the plans were released on 19 December.

The £520-million venture will include facilities for research, development and manufacturing, with space for 22 companies. These will have access to the 150 researchers based in the science centre who will come from the Universities of Bristol and Bath and the Polytechnic of Bristol. Each institution has a 5 per cent stake, which is paid for in kind, with the provision of researchers and support staff.

A public inquiry must be held before the venture is approved because the site is on land released from environmental protection regulations. But Don Carleton, of the University of Bristol and director of the development company proposing the plans, says the planning authorities support the plans. He expects construction to begin next summer, and the park to create 14,000 new jobs. **Christine McGourty**

Tanks to hold more than fuel

Washington

THE US space shuttle's giant external fuel tank will some day carry scientific experiments of its own, according to a memorandum of agreement signed last week between the National Aeronautics and Space Administration (NASA) and the Space Phoenix Program of the University Corporation for Atmospheric Research.

In his 1988 Commercial Space Initiative, President Ronald Reagan offered the external fuel tanks to anyone who could think of something interesting to do with them (see *Nature* 331, 550;1988). At present, the tanks are unceremoniously dumped into the ocean after providing the propellants to boost the shuttle into orbit.

There is an unpressurized, 5,000-cubic-foot space between the fuel and oxidizer tanks that can hold a pallet containing scientific instruments. According to Peter Riva, a spokesman for the Space Phoenix Program, that space can easily accommodate relatively large, low-technology experiments that can be loaded just before launch. Some experiments now being considered are gas releases into the upper atmosphere and detailed studies of the thermosphere.

Initial plans call for using the external tank during sub-orbital flights, but ultimately the Space Phoenix Program would like to find a way to place the tanks in more permanent, slow-decay orbits. There is no fixed timetable for when the external tanks will be used to carry experiments, but Riva expects the first flight will be sometime in 1991.

Joseph Palca

Neuroscience Center

Boston

THE Harvard-affiliated Massachusetts General Hospital has opened a new $18 million interdisciplinary Neuroscience Center. The centre, made up of 11 separate laboratories and with a staff of more than a hundred scientists, students, fellows and technicians, is financed by a $6.4 million grant from E.R. Squibb and Sons, a $5 million grant from the National Institutes of Health, and by a number of other private sources.

Dr Joseph Martin, professor of neurology at Harvard Medical School, will direct the new centre. Martin stresses the interdisciplinary approach of the centre, saying that chronic neurodegenerative diseases might best be tackled by "understanding their causes at the genetic level" rather than a "shotgun" approach of focusing only on particular symptoms of individual diseases. The centre will house the hospital's neurogenetics laboratory where molecular genetic techniques are being used to study Huntington's disease and Alzheimer's disease.

20th-century smugglers use biotechnology

Sydney

In a cloak and dagger operation that could have been lifted from the pages of a spy thriller, a group of wily Australians have combined the traditional trickery of smuggling with high-technology embryo implantation techniques to try to break South Africa's near-monopoly of the $200 million market for mohair wool.

Mohair wool comes from angora goats, the finest of which are bred in South Africa. Exporting them without the permission of the South African National Angora Breeding Society is banned. But in 1986, three Australian farmers raised A$600,000 from Australian goat breeders to try to lay their hands on a herd.

In South Africa they succeeded in buying 269 top quality Angora and Boer (meat) goats. Waiting until Christmas Eve, when they guessed official diligence would be low, they loaded the herd into trucks and set off at night for a 47-hour trip to the border with Zimbabwe. One farmer flew ahead of the convoy in an aeroplane, smoothing out paperwork at more than 20 checkpoints along the way. At the border, customs inspectors were persuaded the trucks contained sheep rather than goats, a move one of the men involved in the trip agreed was "against the spirit of the South African angora industry regulations".

In Zimbabwe, the Australians bred the goats and collected almost 400 embryos which were frozen and flown to the Australian Government offshore quarantine station on the Cocos Islands in the Indian Ocean. The plan was to implant the embryos into surrogate mothers on the Cocos Islands and keep the kids in quarantine. But the original partnership broke up and the frozen embryos were instead sold to Embyrotech, a Western Australian company. Embryotech transported the frozen embryos to New Zealand, which has already built up a herd of 74 Angora kids and 24 Boer kids.

With multiple ovulation and embryo-transfer technology, the number of offspring can be rapidly increased. Once seven years of quarantine are up — essential to ensure the herd is free from the scrapie disease agent — Embryotech has just announced that it will sell all the offspring to Australian farmers, giving them a chance to cash in on the lucrative angora wool market.

Three other angora herds have also been 'imported' to New Zealand from South Africa. In 1987 South Africa introduced legislation that allows the government to confiscate the farm of anyone collaborating in illegal exports. Tania Ewing

A certain uncertainty awaits in Washington's new year

Washington

CELESTIAL mechanics guarantees that in August this year the Voyager space probe will make a historic encounter with the outer planet Neptune. But apart from that, nearly every other scientific endeavour of 1989 is tinged by an uncertainty not felt for 8 years: from 20 January a new man will be in the White House, and although President-elect George Bush is of the same political cloth as his predecessor, there are already indications that new priorities can be expected.

During his campaign for election, Bush promised to raise the status of the White House science adviser to the rank of presidential assistant, but by the year's end when — nearly — all cabinet appointments had been announced there was still no word about who will fill that new position. This may be an indication that science will not in fact receive its promised new importance, but it could just as easily be evidence that Bush has found — as have others before him — that the political and bureaucratic complexities of bringing in a new team can foil the best intentions.

Adding to the uncertainty are a spate of new faces in important congressional appropriations committees. This month, Congress will receive the 1990 budget blueprint prepared by the Reagan administration, but that will certainly be modified by both the Bush administration and Congress before the start of the new fiscal year.

In addition to establishing budget priorities that could spell the end of big science projects such as the Superconducting Super Collider — now scheduled to make Waxahachie, Texas the mecca of the high energy physics world — and the National Aeronautics and Space Administration (NASA)'s Space Station, Congress will also continue to grapple with the issue of scientific misconduct.

The arcane question of the specificity of the Bet-1 reagent may be the central theme of hearings scheduled for early in the year, as a powerful committee led by Representative John Dingell (Democrat, Michigan) resumes its inquiry into a paper appearing in *Cell* co-authored by, among others, Nobel laureate David Baltimore, that has raised complicated issues of how the propriety of scientific data should be investigated. Another committee chaired by Representative Ted Weiss (Democrat, New York), will continue hearings probing conflict-of-interest issues for scientists who work at academic institutions but are supported by private industry.

For NASA, 1988 was a good year, and 1989 promises to be even better. The space shuttle returned to service in September, and a second successful flight followed. Three major scientific missions are scheduled for launch this year; the Magellan Venus radar mapper, the Galileo mission to Jupiter and the Hubble Space Telescope. If, however, the Bush administration decides not to go forward with the space station, NASA will be searching for a new identity, as military and commercial space activities have already been moved elsewhere.

NASA will certainly have a role studying the environment, a topic that will occupy centre stage in 1989. Last summer's drought and heat wave convinced many that greenhouse warming was worth serious study, and finding ways to limit the production of greenhouse gases, including renewed consideration of nuclear power, will be a constant theme.

If new commercial nuclear reactors are still some way off, the Department of Energy must nevertheless finalize plans for a new defence production reactor to restore US capacity to produce tritium and plutonium for nuclear weapons. By the end of 1988, all US reactors capable of producing tritium had been shut down, and a constant stream of newly discovered threats to safe operation of the ageing reactors threatened any early restart.

The National Science Foundation (NSF) is still hoping to see its budget double by 1992, an increase promised by the last administration, but probably out of reach. NSF has moved ahead by providing money for 11 new science and technology centres, and more may be authorized in 1989.

Coping with AIDS will continue to be a major preoccupation of the US Public Health Service and its subordinate National Institutes of Health (NIH) in Bethesda and Centers for Disease Control in Atlanta. Also in Bethesda, the NIH human genome office, led by James Watson, will get into full swing next year, and W. French Anderson, along with colleague Steven Rosenberg, should begin the first-ever experiment involving the introduction of genetically engineered cells into human subjects.

Biomedical research will continue to face stiff challenges from two well-organized lobbies. Animal rights activists will continue to push for restrictions on the use of animals in research, and anti-abortion groups will seek to prohibit the use in research of fetal tissue from induced abortions. But Bush's choice of Louis Sullivan for Secretary of Health and Human Services has at once outraged anti-abortion lobbies and proved that what was past is not necessarily prelude.

... agreement with China ... the scene for 1989

New Delhi

IN India, 1988 was seen out with the signing of a new agreement with China on cooperation in science and technology. After having having been cut off from one another for 30 years, scientists of the two countries will now cooperate "on the basis of equality and mutual benefit".

Set alongside increasing technological ties with the Soviet Union — including a promise to aid construction of two nuclear reactors on India's east coast — the agreement may signal a trend for Indian scientists to forge closer ties with colleagues in the communist world. Indo–US cooperation reached a low point in 1988 with disputes over patents and protection of intellectual patent property rights.

The five-year science pact with China is one of the three agreements signed during Prime Minister Rajiv Gandhi's pre-Christmas visit to Beijing. The agreement will provide a framework within which Indian and Chinese institutions can conclude protocols and research contracts. Agriculture and industry will take priority but other forms of technological cooperation may be mutally agreed upon. The agreement also provides for exchange of scientists, documents and journals, and holding of seminars and workshops. From a broader political viewpoint, this agreement and two others on culture and trade are seen as a prelude to an accord on the contentious border issue.

Earlier in 1988, India's success with its first remote-sensing satellite (IRS-1) was offset by the failure of the ASLV-3 launcher and the trouble with communications satellite INSAT 1-C.

India's ambitious space programme hinges on the next flight of ASLV-3 and the May 1989 launching of INSAT-1D. The heavy launch vehicle programme could even be terminated if India decides to concentrate instead on the hyperplane, the Defence Department idea for a space-plane that collects oxygen fuel in flight. Soviet help has been sought.

Indian scientists scored a success with their first low-cost parallel-processing computer and by predicting accurately the behaviour of the monsoon for the first time since the creation of the meteorological department. The government will now launch a three-year project to build a supercomputer.

In the medical field, the birth control vaccine developed by the National Institute of Immunology will enter phase-two trials this year. Another vaccine for sterilizing stray dogs and unproductive cattle has been developed by the same institute and is now for sale.

Materials science, biotechnology and energy are key areas for funding in 1989. The first wave-power plant is being built on the southern coast and a plant is to be set up in Gujarat to extract gas from coal without mining. One nuclear plant will be commissioned in 1989 and 20 more will be built over the next 11 years. The Department of Atomic Energy will have no problems with funds but will find it increasingly difficult to overcome opposition from environmentalists.

On the science policy front, Gandhi has still not acted on his advisers' suggestion for a national commission to integrate science and technology with economic planning. Two controversial decisions on liberalizing seed import and permitting entry of Pepsico in the beverage market have been blamed on the lack of a well-defined technology import policy.

Gandhi has asked scientists to help solve India's problems through technology missions. Telecommunications has provided the first success. India has built its own electronic telephone exchange for cities and the mission intends to supply one exchange every day to rural areas. Over the next few years, backing will be given to missions for drinking water, immunization, cattle improvement and mosquito control. But as yet there is no mission to relieve the sufferings of the thousands of Bhopal gas victims who observed the fourth anniversary of the tragedy on 3 December by burning effigies in front of the Union Carbide factory.

K.S. Jayaraman

Still no hope of a coherent Australian science policy

Sydney

AT the end of 1988, Australian scientists finally found their voices. Dissatisfaction over reduced funding and the constant calls by the government to make science more commercial angered scientists sufficiently for them to reject the label of "wimps" given by Minister of Science Barry Jones and come out of their laboratories and protest.

Hopes had been raised that a coherent long-term science policy would emerge from the reports of a government inter-departmental committee (IDC) set up to look into funding and policy needs and from the Smith committee investigating university research requirements, even though the former contains no members from the scientific community.

But scientists seem likely to be further disappointed. The IDC report was presented to the cabinet in December and, although it has not yet been made public, details of its recommendations are known. The report acknowledges the problems of Australian science: poor funding, increasing student-to-staff ratios and the reduction in graduate students, but warns that any general topping-up of funds might be interpreted as "too little too late . . . The Government (would be seen to be) wavering in its policy directions".

In response to criticism that the administration of science is too fragmented, the report recommends a permanent committee of senior bureaucrats reporting to the Minister of Science to co-ordinate policy and funding. A "distinguished scientist" would also be appointed for a two-year term as Chief Science Adviser to the minister.

The IDC report allocates A$20 million to meet the most urgent needs for laboratory equipment in the year ending June 1989. But the funds cannot be given out until the Smith committee reports in late March 1989. The amount is much less than that requested by scientists. CSIRO alone requested an extra A$75 million for next year.

The government seems relentless. A spokesperson for Senator John Button, the Minister for Industry, Technology and Commerce said "we are trying to force scientists to get funding from the private sector. Historically scientists go away and set their own priorities. They will just have to get used to living in the real world."

But big business may not be interested. Dr Max Whitton, chief of entomology at CSIRO, said "science cannot attract commercial funding if there isn't the viable operating base to attract partners". Professor David Penington, vice chancellor of the University of Melbourne, agrees. "Industry keeps its distance from us rather than developing a vigorous partnership. The idea that this could be resolved through a directive from Canberra is nonsense. Incentives and deregulation are needed."

Australia's scientists are fearful that in 1989 the downward spiral for research funding will continue. The Federation of Australian Scientific and Technological Societies (FASTS) with 60,000 members is determined to have science funding put on the political agenda, particularly with a federal election likely at the end of the year. Professor Frank Larkins, president of FASTS, said: "Fundamental science is the foundation of applied science.

"If the government wants science and technology to pay economic dividends, we need increased funding and a five- to ten-year policy."

Tania Ewing

Too many students, too little cash in German universities

Munich

1988 ended on a note of uncertainty in West Germany with students demonstrating at 40 universities to protest against overcrowding and lack of funds. Overcrowding is at record levels, with at least twice as many students registered as the universities are designed to handle.

A new DM2,100-million government 'emergency programme' announced in mid-December will help, but will make a real difference in only a few faculties. And even if the height of the *Studentenberg* begins to come down in 1989, many professors will continue to be hard-pressed to find time for their research.

University researchers have also been hit by a budget squeeze. The Deutsche Forschungsgemeinschaft (DFG) — the main university research funding body — found it could fund less than half the applications in its priority programmes (*Schwerpunktprogramme*). Overall, DFG turned down more grant applications than ever before, raising worries that young people will forced out of research careers. But DFG takes heart from the better quality of grant proposals.

Researchers at the Max Planck Society are better off. A modest increase in the 1989 budget comes on top of Nobel prizes in 1988 for three of its researchers: Hartmut Michel, Johann Deisenhofer and Robert Huber. Michel has since moved to Texas, but Deisenhofer and Huber remain at Max Planck Institutes.

The Large Research Establishments (*Grossforschungseinrichtungen*, GFE), like the Max Planck Institutes, do not have to worry about the annoyance of too many students. But both associations have promised to cooperate more with the universities, in keeping with the recommendations released in May by the science council (*Wissenschaftsrat*). The council fears an increasing division between universities and research institutes.

In 1989, GFE are likely to place greater emphasis on health research now that Harald zur Hausen of the German Cancer Research Centre is chairman. They have also announced their intention to work more closely with researchers in other European countries.

International cooperation is also the theme for West Germany's burgeoning space programme. The Research and Technology Ministry (BMFT) will increase its investment by 11.8 per cent to more than DM1,300 million in 1989, keeping pace with France and the other members of the European Space Agency. BMFT has stepped up its efforts on its second space laboratory, to be launched by the US shuttle in late 1991. West German groups have also sent payloads on a Chinese rocket and on the Soviet probe to Phobos.

Cooperation may come harder in areas where ethics are involved. Differences began to appear in 1988 between West Germany and other European Community members about research on human embryos and the sequencing of the human genome. Both are emotive issues that will command more attention in 1989.

AIDS was less of a public issue in the second half of 1988, but the liberal policy of the West German government towards AIDS carriers may be in for some changes in 1989 under a new and untried Health Minister, Ursula Lehr, who replaced the veteran Rita Süssmuth in November. Peter Gauweiler, a hard-line conservative, lost the AIDS portfolio in a Bavarian state government reshuffle. On the research front, a modest BMFT programme to establish centres of excellence for AIDS research has yet to bear fruit.

1988 began and ended with nuclear 'scandals' of different kinds. In January, hundreds of mislabelled barrels of nuclear waste turned up unexpectedly at nuclear waste storage sites across West Germany. In December, public trust was dealt another blow when a reactor mishap at the Biblis nuclear plant near Frankfurt was found to have been covered up. Nevertheless, Chancellor Helmut Kohl's centre-right coalition government held fast to its nuclear programme, just as it had after Chernobyl.

1989 will find legislators watching the clock as the Kohl government's second term winds down. The next elections for the Bundestag (parliament) are not due until 1990 but five Landtag (state parliament) elections in 1989 will set the stage for the big campaign. **Steven Dickman**

Return to the good old days of plenty for French researchers

Paris

FRENCH scientists began 1988 facing cutbacks in basic research spending and with instructions to begin paying homage to industry. That, said President Jacques Chirac and science minister Jacques Valade, was the way to bring France into a united European market in 1993, creating the opportunity to compete with Japanese and US technology. But elections in the spring brought a change of government and, with it, hopes of a return to the good old days. Radical changes were made by the incoming socialist government, but it was a long time before a coherent policy was formulated.

Minister for Research and Technology Hubert Curien's first move was to rectify "flagrant deficiencies" in research funding. A $195 million handout was given in June, doctoral bursaries were increased and 150 new research posts created. In the autumn Curien finally gave substance to President François Mitterrand's promises with an extra $484 million increase in his 1989 budget, a 7.5 per cent increase over 1988 and way ahead of inflation.

With the new government settling in during the summer, nothing new was done in the fight against AIDS, even though France continued to rank highest in Europe for the number of AIDS sufferers. Finally, in November, Curien gave researchers $24 million, saying that if it was not enough they would get more, while Health Minister Claude Evin launched a new $8 million AIDS information campaign. 1989 will show whether it succeeds in converting Roman Catholics to the condom, outlawed by the Pope.

The French space industry, major shareholder in the European Space Agency (ESA), continues to boom. Sixteen satellites have been launched in the past 15 months. Ariane 4, the new workhorse heavy-lift launcher, also successfully completed its maiden flight in 1988. Arianespace enters the new year with $2,240 million worth of orders for the launch of 36 satellites. Now all eyes are on Ariane 5, which will be used to send the Hermes shuttle on its way to Europe's Columbus contribution to the US space station, also finally approved in 1988. Work has started at ESA's Kourou launch site to build a new launch complex for Ariane 5, due to fly in 1995, to the chagrin of British space scientists whose HOTOL shuttle is still looking for a sponsor.

Reform, the unlucky buzz-word of the last government, has been replaced by 'evaluate'. The high levels of public spending needed to realize the new government's declaration of research and education as priorities will need careful housekeeping. Curien has introduced a new watch-dog committee to oversee the cost-effectiveness of research. 1989 will also see Jacques Benveniste's research on the 'molecular memory' of water scrutinized as part of a routine, but major 'in-house' review of his laboratory.

Besides 'evaluate', the government's will is to 'co-ordinate'. No major policy decision has been taken without an in-depth report with the emphasis on inter-ministerial co-operation. In France, 1989 will be the year of committees, but only time will tell if their designs produce horses or camels. **Peter Coles**

Japanese science looking to the West and thinking big

Tokyo

IN Japan, 1989 begins with increasing concern that the Recruit stock market scandal, which has already forced the resignation of Finance Minister Kiichi Miyazawa and top leaders in industry, will sweep away others in high places. Further revelations of influence peddling in the political world may mar a year in which Japan wanted to 'internationalize' its image, not least in science and technology.

1989 will be an important year for 'big science'. The Ministry of Education, Science and Culture (MESC) will make available several tens of millions of dollars to begin development of the world's largest helical fusion device at a new institute in Gifu Prefecture. And the Science and Technology Agency will pour similar sums into development of the world's largest synchrotron which is expected to be sited at a "technopolis" in Hyogo Prefecture, near Osaka. Both machines are scheduled to begin operation in the mid 1990s.

Japan will continue its modest but successful space programme with the launch of three satellites. The National Space Development Agency will put up a meteorological satellite (GMS-4) and a marine observation satellite (MOS 1-b). In February, the Institute of Space and Astronautical Science (ISAS) will launch a satellite (EXOS-D) into the 'bow wave' of the magnetosphere above the polar regions of the Earth to observe the formation of aurorae.

Eyes will be on the Space Activities Commission to see if (as is expected) it will grant a request from ISAS to increase the size of its rockets. For the past 20 years, ISAS rockets have been limited to a tail diameter of 141 cm under an agreement between the Science and Technology Agency and MESC. But larger rockets are needed to fulfil ambitious plans to send probes to the planets and beyond.

The first batches of young Western scientists invited under new postdoctoral fellowship schemes will begin arriving in Japan in the next few months. The government fellowships were introduced in the face of US pressure on Japan to open up its research system to Western (in particular US) scientists, and became available shortly after signing of the US–Japan Science and Technology Agreement in Toronto in June. But the schemes are suffering from a lack of applicants and it is uncertain if they can be expanded as planned in fiscal year 1989.

Japan's Human Frontier Science Program, which will be set up as a foundation in Europe in October, may fare better. A 'pilot' programme of five grants offered by the Ministry of International Trade and Industry (MITI) last summer received a flood of applicants from scientists of the summit nations.

The grants, for research on higher-order brain functions or molecular-level recognition and response, are open to scientists in institutions located in three or more summit nations, one of which must be Japan. When the foundation opens in Europe, the grant programme will be expanded and the foundation will also award postdoctoral fellowships and stage international workshops.

It remains to be seen how much control the Japanese government will maintain over the foundation. MITI projects have tended to suffer from inflexibility; much will depend on the make-up and nature of governing bodies to be established for the programme.

Speedy internationalization will be seen in the private sector. In May a consortium of UK, US and Japanese companies headed by Britian's Cable and Wireless and C. Itoh of Japan will begin international telecommunication services in competition with Japan's Kokusai Denshin Denwa (KDD). The consortium will also begin laying a trans-Pacific optical fibre cable to compete with a new KDD cable that will come into operation in March.

Research and development will begin to move abroad with the opening of an institute sponsored by electronics giant NEC at Princeton in May. The institute is expected to set a trend, as is a three-year joint agreement between Hitachi and Texas Instruments to develop 16-megabit dynamic random access memory chips.

The Recruit scandal is thus all the more damaging because it comes at a time when Japan is trying to improve its image overseas. The Recruit saga reveals that 'money politics' still rules Japan and little has improved since the Lockheed scandal of the 1970s which brought down former prime minister Kakue Tanaka. Many questions remain unanswered, particularly regarding the involvement of former prime minister Yasuhiro Nakasone in the affair. And although Prime Minister Noboru Takeshita is now riding high because of the successful passage of a major tax reform bill, he is not immune from attack.

Takeshita's strategy will be to try to put Recruit behind him by launching his pet 'home town' plan for the development of the regions and decentralization of Tokyo. But the popularity of his administration has plummeted and he will have much to do if the party is to choose him to continue as prime minister in the autumn.

David Swinbanks

Glasnost doing *perestroika* in

London

DURING 1988, the Soviet Union had to come to grips with *glasnost*. From the February fire at the Academy of Sciences library in Leningrad, through the posthumous revelations of Valerii Legasov about the Chernobyl disaster, and up to questions as to why, after so much research investment in earthquake prediction, Spitak and Leninakan were unprepared, people in authority have had to accustom themselves to the unfamiliar sensation of being publicly questioned.

In science and technology, passing responsiblity for failures back and forth between the research and production sectors will no longer do. The All-Union Academy of Sciences has completed its replacement of superannuated personnel (and elected Andrei Sakharov to its presidium), but has had its own scandal: the destruction of a major archaeological site for the building of its Crimean rest home. There have been major reassessments of history, many posthumous rehabilitations and 'rediscoveries' of disgraced party leaders, scientists, and scholars.

Yet *perestroika* (restructuring) is running slower than *glasnost*. Self-financing for industry and family leasing for agriculture have yet to show their economic results, and some publicized reforms have failed to materialize. Many managers still seem beset by the 'gigantomania' of the Brezhnev years. The most promising development of the year — an education reform that, it is promised, will at last allow excellence to flourish — was announced only in its closing days.

A major feature of 1988 has been the increase of 'national' demands throughout the 15 constituent republics of the Soviet Union. Some of the demands — such as the development of scientific vocabularies for the 'national' languages based on 'universal' rather than Russian roots, or the establishment of a separate Academy of Sciences for the Russian Federal Republic — should not prove too difficult to satisfy. Nor should some demands of environmentalists — such as the campaign against the chemical works in Erevan. But recent local campaigns in the energy sector require a change in policy.

Opposition to nuclear power has grown and several major projects — including the Minsk nuclear power and district heating station, and the Vitebsk, Chynyryn and Crimean nuclear power stations — have been cancelled or converted to conventional fuel. The Armenian nuclear power plant will be phased out by 1990, and further extension of the Ignalina power station in Lithuania has been cancelled. But these concessions to local opinion still

better than Soviet Union

remain decisions taken in Moscow. The governments of the individual republics still have no say in the development of nuclear power within their territories, and so far only the Lithuanian Supreme Soviet has decided to defy Moscow and withdraw its financial support from nuclear energy.

There is no clear alternative to the Soviet Union's commitment to nuclear power. Large hydroelectric dams are increasingly seen as uneconomic and harmful to the environment, except perhaps single dams on mountainous rivers. But in the mountains of Soviet Central Asia, the local population is alarmed about the seismic hazards of large dams. Proposed solutions such as solar energy in Moldavia or wind farms in Byelorussia seem somewhat utopian.

In the coming year, Soviet energy planners will have to address the difficult problem of restoring confidence in the All-Union energy programme.

Confidence in the space programme also needs to be restored. Space 'achievements' are increasingly viewed by the Soviet public as wasteful attempts to gain international prestige. The partial failure of the Phobos mission did not help to arouse enthusiasm for a manned mission to Mars some time between 2010 and 2020, and a new society to stimulate interest in space among young people has so far failed to take off. The socialist allies feel excluded by the new Soviet commitment to 'international' projects involving France and neutral and non-aligned nations.

Perestroika has set a challenge to the socialist bloc. Reactions range from those of Hungary, where the breakaway Democratic Trade Union of Academic Workers is now a recognized part of the political scene, and Poland, where the Academy of Sciences has just rejected a government report on the environment, to Cuba, which opposes the whole idea of *perestroika*, and East Germany, which claims that reform is unnecessary. In between come Bulgaria, where lysenkoism has only just been finally dispatched with a massive change of personnel in the Academy of Sciences, and Czechoslovakia, where calls for restructuring remain largely on paper.

An encouraging development in 1988 was the holding of international conferences by two new non-governmental organizations based in the socialist bloc — the Hungarian-based International Association of Physics Students and the Bulgarian-based 'Ecoforum'. Both meetings attracted wide support from East and West and were hailed by Soviet 'establishment' participants as a manifestation of the recent trend in 'informal' initiatives.

Guarded optimism greets increased funds in Britain

London

BRITISH science enters 1989 on an optimistic note, even though 1988 saw no improvement in university finances nor in those of the research councils. The raised spirits in the research community stem from the money for science won from the Treasury by the Department of Education and Science. An extra £95 million is being added to the budget of the research councils for the year 1989–90, an increase of 16 per cent on 1988–89. Specific programmes will absorb much of that money, but, with the remainder, the research councils will be able to support some more research and fund a few more alpha-rated projects. Exactly how the money is to be spent will be announced soon.

Although the award is not extravagant, it is a real increase in science spending and reflects a change in the government's attitude towards science. That change was marked by a speech made to the Royal Society in 1989 by the prime minister, Margaret Thatcher, in which she expressed a commitment to the public funding of basic science.

But research dubbed 'near-market' suffered at the hands of the government in 1988, and the effects of this hit the research councils hard. A review of the work carried out by the Agricultural and Food Research Council (AFRC) identified research valued at £33 million a year as near-market. If the cuts are implemented in 1989, the council estimates that 750 jobs could be at risk.

The Natural Environment Research Council (NERC) was another victim of government policy regarding near-market research. In 1988, the council was forced to cut its support for university research by £2.6 million and to cancel the grants round for October. It announced 130 redundancies to take effect before April 1989, some of which will be compulsory. The council hopes that the worst is now over and that 1989 will be more stable. But the council's new chairman will be fighting to retain not just financial support but the council's identity as the year is likely to bring a merger with the AFRC.

The question of the structure of the research councils resurfaced in 1988 and two committees will report early in 1989 on what form support of the biological sciences should take. The House of Lords committee reviewing support for the biological sciences recommended a merger between the NERC and the AFRC in its interim report in 1988, but in its full report may recommend further evolution towards formation of a council for all the biological sciences which would incoorporate some research of the Science and Engineering Research Council as well as the Medical Research Council. A committee for the Advisory Board for the Research Councils will also give its view in the spring.

Biologists in the academic science community must be looking forward to 1989 with some trepidation. Following the reviews of the Earth sciences, chemistry and physics in universities, which were published in 1988, is the review of the biological sciences. A draft report is now ready; if, like the chemistry and physics reviews, it recommends a concentration of resources in departments of a minimum size, 1989 may witness the beginning of the end of the small science department.

Overseeing the restructuring will be the new Universities Funding Council (UFC), set up in 1988 to take over from the University Grants Committee. The new chairman of the council, Lord Chilver, is embroiled in controversy even before he takes up his post, declaring his view on access to higher education: courses should be available to those who value education highly enough to commit resources to it. His views will find favour in government, which made moves in this direction in 1988 with the publication of a policy document on student loans. Issues such as the repayment of loans and the involvement of commercial banks are still to be resolved, but the government aims to introduce the system in 1990. More protests from students — such as those resulting in clashes between students and police in the streets of London in 1988 — seem likely in 1989.

Dominating the work of the heads of universities in 1988 was the Education Reform Act. On the question of the abolition of tenure, the government emerged the victor — abolition will go ahead — but on the introduction of a system of 'contract funding', the universities' heads emerged victorious. They won a concession from the government that before any conditions are laid down on funds from the UFC, bodies representing the universities will be consulted. But the value of this victory was thrown into question when the Committee of Vice-Chancellors and Principals received from the Department of Education and Science a draft copy of the guidelines to govern the relationship between the government, the UFC and the universities, which described controls the government would have over universities' finances. While the government is encouraging universities to seek a broader base of funding, it seems determined to monitor those finances. Retaining their autonomy will still be high on the agenda of the universities in 1989.

Christine McGourty

History of 'biotechnology'

SIR—Although old uses of the word 'biotechnology' have been noticed[1], no satisfactory lineage has been traced. I should like to draw attention to a source that fulfills three strict criteria: a self-conscious claim to novelty, recognition from others of that novelty and noticeable use of the word.

In 1919, Kark Ereky, the Hungarian agricultural economist and, briefly, minister of food in the counter-revolutionary government, published an 84-page manifesto entitled: *Biotechnologie der Fleisch-, Fett- und Milcherzeugung in landwirtschaflischen Großbetrieb*. Following the precedents of chemical technology and mechanical technology, Ereky coined his new word to cover the interaction of biology with technology, connoting all production by means of biological transformation:

Auf Grund des gleichen Gedankenganges weist der Verfasser alle die Arbeitsvorgänge, bei denen aus den Rohstoffen mit Unterstützung lebender Organismen Konsumartikel erzeugt werden, dem Gebiete der Biotechnologie zu. [original emphasis][2],

which may be translated as: "On the same grounds the author classifies as biotechnology all the lines of work by which products are produced from raw materials with the aid of living organisms".

Ereky's book was well received and its originality recognized. *Die Naturwissenschaften* described the author' goal as a new branch of knowlege that he calls *Biotechnologie*[3].

Thereafter, the word biotechnology appeared in various contexts in the 1920s and early 1930s. Some applications clearly follow from Ereky's formulation. It appears immediately as a heading in *Zeitschrift für Technische Biologie*[4].

Other uses should not, however, be attributed to Ereky. The similiar word *Biotechnik* had come into use at about the same time, and although there is a difference in nuance, even in German the two words could be interchanged[5]. In English translation, the distinction is almost entirely lost. *Biotechnik* therefore spawned the alternative meaning of the English biotechnology. In one of the first English uses, *Nature* entitled a 1933 editorial "Biotechnology"[6]. Dealing with technology and the problem of maintaining the quality of the human species, its title seems to refer to the concept of *Biotechnik* presented by Goldscheid in his social biology of 1911[7].

Since then the word biotechnology has been reformulated many times: in 1947 to describe ergonomics[8], in 1962 as the title for a new journal dealing with biochemical and microbiological engineering[9] and in 1979 to describe the potential of genetic manipulation[10]. The distinction between different usages has often been overlooked because they do share an important connotation: a new biological approach to a great range of industries. This breadth was foreshadowed in the aftermath of the First World War by Ereky's formulation of the concept of biotechnology.

Primer availability

SIR—The possible applications of the polymerase chain reaction (PCR) (see ref. 1), which amplifies specific DNA sequences during successive cycles of DNA denaturation and extension of specific oligonucleotides (primers) by DNA polymerase, are enormous, both for basic research and for molecular diagnosis of inherited disease. In most laboratories involved in molecular diagnosis of genetic diseases, PCR will gradually replace routine DNA techniques of Southern blotting and hybridization with radioactive probes. A prerequisite to perform PCR, however, is the availability of the specific primers.

Recently, I requested primers for prenatal diagnosis of two common genetic diseases. On both occasions the answer was negative, although the papers describing the primer sequences and their possible applications had already been published. Costs of synthesis and distribution of the primers were probably the main factors hampering their release. If this becomes a general policy, laboratories will each have to face the problem of synthesizing the respective primers for all the different diseases they are studying.

Most companies charge $1,000–$2,000 to synthesize 10 micromoles of a 20–30 base pair oligonucleotide, which is enough to provide 100 laboratories with primer for 1,000 PCRs. With small fees ($15–$20) from each of the laboratories requesting the primers, costs for synthesis and distribution could easily be covered. It might be opportune, for logistic reasons, to centralize primer synthesis and distribution in an organization such as the American Type Culture Collection (ATCC), which has become a central depository and distributing organization for DNA sequences.

The free release of DNA probes to laboratories throughout the world has contributed largely to the exponential increase in our understanding of genetic diseases. For the future, it is essential to guarantee the availability of the necessary PCR primers.

Soviet refusniks

SIR—We appreciate the increase in the number of exit visas from the Soviet Union granted to Jews, including some long-term refusniks who want to emigrate.

But despite the sizeable increase in the number of visas, a substantial number of long-term refusniks have no foreseeable hope of leaving. Several of them have been waiting for more than 15 years, and some have been told that they will not be allowed to leave until 1992 or 1996.

In most cases, the reason given is that of having access to secrecy. For instance, the Uspensky family has been refused because Igor Uspensky's mother, who is in her late seventies, worked in the Ministry of Agriculture until she retired 12 years ago. She has been told that the reclassification of her secrecy will take place after 1996 (when she will be 84 years old). This not only prevents her from leaving but also her son, daughter-in-law and grandsons. If they were not so tragic, one could put such classifications in the realms of the 'Theatre of the absurd'.

Biblical criticism

SIR—The recent note (*Nature* **335**, 203; 1988) on the history of the survival of the Aleppo Codex describes the codex as the Hebrew Pentateuch, the first five books of the Old Testament. But the portion reproduced is of a passage from the Book of Judges (9:57 to 11:2). It includes the first part of the story of Jephthah — his exclusion from his paternal inheritance by his step-brethren because he was "born of another woman".

MYER H. SALAMAN

23 Bisham Gardens,
London N6 6DJ, UK

● The Aleppo Codex originally contained all the books which now constitute the Old Testament; about one-third of the text has been damaged or destroyed. Editor, *Nature*

Prospect for a new year

The temptation to guess what lies even immediately ahead must be resisted, as the prospects for fundamental physics show all too plainly.

PRETENDING to predict the future of discovery is not merely foolish, but a contradiction in terms. Discoveries are, of their nature, unexpected to some degree. What follows should therefore kindly be regarded not as a set of predictions but as a list of wishes. The exercise is worthwhile not for its content, but because it reflects the way that at any time there is a sense of expectation attached to some fields of research, and of dormancy to others. Perhaps a later Thomas Kuhn will think it worthwhile to compare these expectations with the realities that emerge.

Expectations are most vividly engendered by big machines, most of which are built to timetables advertised in advance. The year ahead should see the commissioning of two machines of great importance — the new electron-positron collider (LEP) at the European high-energy physics laboratory (CERN) at Geneva and the Hubble Telescope, which should at last be launched when the US shuttle is back in service and has room to spare. Curiously, neither machine has done as much to lift the spirits of those concerned as might have been expected.

The difficulty at CERN is that, this time, there is no obviously spectacular prize to win, such as the predicted discovery of the mesons that mediate the electro-weak force, and whose masses were predicted to be within the range of collisions between protons and antiprotons in CERN's super-synchrotron. Instead, as if discomfitted that the top quark has not turned up in the same range of energy, and as uncertain as ever where the Higgs particle may lie, people are now hoping that 'new physics' will provide LEP's fun and excitement. Nobody belittles the importance of being able to measure the electro-weak bosons in plenty, but the hazard of new physics is the difficulty of telling the difference between the real thing and spurious data.

The disappointments of the Hubble Telescope are different: frustration and continuing uncertainty. The fact that an instrument which, if it works half as well as planned, is likely to do more to change our view of the Universe than all this century's optical instruments put together should still be sitting on the ground at Los Angeles after three years, waiting for a firm launch date, may help researchers appreciate their properly modest place in the wider scheme of things, but it speaks wonders for the endurance of the human spirit in the face of frustration that the Space Telescope Science Institute and its principal investigators remain cheerful.

Some say the delay may have helped ensure success. The guide stars on which accurate pointing of the telescope will rely have been more accurately and comprehensively measured, while ground access has got rid of an optical misalignment together with a huge amount of unwanted dust. But the telescope has been frozen in design during a period when telescope designers have been more innovative than ever. There is also some concern that the modified shuttle may not be able to put the telescope into a safe orbit.

Either of these machines might help throw light on the great cosmological issues — but not in their first year. Appropriately, the Hubble Telescope should eventually provide a reliable distance scale for the Universe, and thus decide what Hubble's constant is, but everybody understands what painstaking work that must be. Even the issue of what quasars are will take time, though opinion does seem to be drifting towards the view that the nuclei of most kinds of active galaxies embody black holes; sadly, less attention is being given to questions such as the lifetime of the active phase and the related question of whether an active phase is an evolutionary stage of most, perhaps all, galaxies.

Expectations of the contributions likely to be made by particle physics to cosmological understanding are now less uniform than a few years ago, when the Big Bang seemed to many to be nature's practical demonstration that the particles of the known hierarchy (nobody calls them "fundamental" any more) are related to each other by the progressive breaking of a natural symmetry in a mass of expanding and thus cooling gas. Part of the trouble is psychological; no sooner had the particle theorists sketched in the details of the Big Bang in the first few seconds and minutes (with observationally important predictions of deuterium abundance and spatial uniformity in the early Universe) than, it seemed to cosmologists, they fell under the spell of string theory, which is a way of accounting for the differences between particles by means of dynamical variables in dimensions (most commonly, there are six of them) which are hidden from observation, or are "collapsed".

In principle, of course, particle physicists may justly say that the attractiveness of string theory does not imply an abandonment of the exciting vision of how particles run down the heirarchy in the Big Bang, transforming from one species to another in the process, but merely a quest for a more natural explanation of the relationships between particles.

But they have nevertheless damaged the simple view that particle physics and cosmology would come together through the Big Bang in at least two ways. First, the mere suggestion that there may be unobservable dimensions is an unsettling reminder of other conundrums, the quantization of gravity, for example. (The question whether the hidden dimensions may embody the hidden variables for which Einstein fought is too little discussed.)

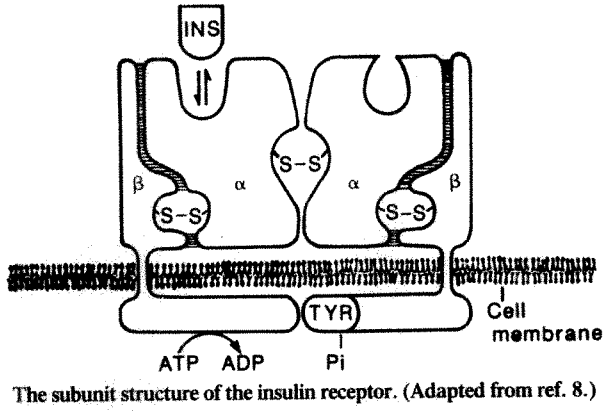
Second, if the dimensionality of space–time is to have a place on the agenda of discussion, should not attention also be paid to the arguments in the second half of Stephen Hawking's recent book *A Brief History of Time* that the Big Bang is an illusion brought about by occupancy of what is bound to seem a Universe in a corner of a larger structure?

It would be good if there were some progress in dealing with this muddle in the year ahead, because people's instincts are sound and the thinking will have to be done at some stage. On a less abstract but equally teasing plane, it does seem certain that 1989 will be the year of Berry's phase — the notion that for any mechanical system represented by a complex field (such as a common-or-garden electronic wave function), whose phase is supposed to have no physical significance, each characteristic of the system can be used to define a phase in such a way that supposedly identical states have different phases, which may be measured as, or inferred to be, different. Abrahamov and Bohm, independently of M.J.Berry, have shown that the supposedly insignificant complex phase of Maxwell's electromagnetic potential is measurable. Is this another way of importing hidden variables? People are now so busily generalizing Berry's argument that we should know what it means before the year is out. The Nobel physics committee would be well advised to plump for this trio before it is denied the topic by an embarassment of choice. After all, the looked-for explanation for high-temperature superconductivity cannot now be found before 1990.

John Maddox

Cell biology

Reception and transmission



Asser S. Andersen

THE activity of cell-surface receptors is in many cases controlled by their association state in the membrane, and the association state is in turn regulated by the attachment of the ligand. Rutter and his colleagues in San Francisco now show[1] that this ligand-dependent association can be mimicked in free solution by the extracellular domain of the insulin receptor. The precise relationship between receptor association and the biochemical events that the receptor controls in the cell is less well-defined, but here too there are some new pointers.

Cell biology and endocrinology have both come a long way since the first evidence that insulin can regulate the activities of a cell without actually going inside was met with incredulity. Signal transduction has now become almost a discipline of its own, and the insulin–insulin receptor system remains the prime example. The way it works is as follows. The insulin receptor, embedded in the cell membrane, is a heterotetramer of four subunits ($\beta\alpha\alpha\beta$) held together by disulphide bonds (see figure). Insulin binds tightly to the extracellular α-subunits, causing the activation of a tyrosine kinase activity which resides in the intracellular domain of the β-chains. The β-subunits then phosphorylate each other, leading to a rise in kinase activity. A still largely uncharacterized regulatory cascade is set in train, involving the phosphorylation of several cytoplasmic proteins. A review of these processes published some years ago was entitled "Insulin binds, and then something happens": although the frontiers of ignorance have been pushed back since then, there are areas that are still shrouded in fog.

To cell biologists, the question of greatest interest must still surely be how the binding of the insulin molecule activates the receptor, and here there has recently been great progress, much of it based on the introduction of alien insulin receptors into mammalian cells in culture. The α- and β-chains are synthesized *in vivo* on a single messenger RNA and then proteolytically separated and inserted into the cell membrane.

Johnson *et al.*[1] have transfected cells of a mammalian (CHO) cell line with complementary DNA encoding either the whole $\alpha\beta$ ensemble or truncated versions lacking most of the β-chain, so as to eliminate both the transmembrane and kinase domains. These secreted 'ectodomains' emerge with the correct quaternary structure (two disulphide-linked α-chains, each with its vestigial β-chain), and properly finished in terms of glycosylation. They bind insulin with fully developed affinity (which is not surprising, for the insulin-binding domain is intact). The striking observation of Johnson *et al.*[1] is that when insulin is added to a solution of purified ectodomains, these entities associate into small clusters or, depending on the concentration, long aggregates, which branch or loop back on themselves. The authors infer from the similar effect of epidermal growth factor (EGF) that the aggregation is a consequence of mere occupancy of a ligand site, rather than a specific effect of insulin. (On the other hand, although the EGF and insulin receptors are structurally related, and EGF does perturb biochemical responses to insulin in some cell types[2], it has never been found actually to compete with insulin on the insulin receptor.)

The subunit structure of the insulin receptor. (Adapted from ref. 8.)

Other groups have also tinkered with insulin receptors. In particular, Maegawa *et al.*[3] have introduced a truncated recombinant version of the human insulin receptor, devoid of kinase activity, into rat fibroblasts which have the normal (or even an increased) complement of functional receptors. It turns out that these alien and silent receptors do not interfere at all with the action of the endogenous receptors, up to the point of phosphorylation of the β-chain and stimulation of its kinase activity. But thereafter, things go wrong: the endogenous receptor fails to phosphorylate its cytoplasmic substrates, and the transfected cells show none of the normal physiological responses to insulin binding. An interesting (but by no means the only) explanation could be that receptor aggregates are needed to generate biological activity, and complexes of the active with the inactive sort are not functional. The CHO cells that make human insulin receptors in addition to their own[1] have yielded another morsel of evidence for the importance of receptor aggregation[4]: when there are more receptors, fewer insulin molecules are needed to generate a given response. This implies that the closer the receptors are in the plasma membrane the better they amplify the binding signal.

Using the more homespun methods of traditional biochemistry, the groups of Pessin[5] and of Kahn[6] have cast new light on the early steps of insulin action. Sweet *et al.*[5] find that mild reduction causes the heterotetramer to dissociate into $\alpha\beta$-dimers. When incubated with insulin under oxidizing conditions, these revert to the tetramer, showing again that extracellular ligand regulates association state.

Shoelson *et al.*[6] re-examine an old mystery — that trypsin can mimic the effects of insulin in various cells. Their observations suggest that a proteolytically induced relaxation of the α-subunit releases the steric constraints which normally keep the β-subunits from phosphorylating each other. Such a model is consistent with the properties of another engineered fragment: a truncated insulin receptor, lacking the insulin-binding domain, confers the complete gamut of insulin responses on the cell in which it is expressed, without the need for insulin[7]. So it seems that the function of the α-subunit is to keep the β-subunits dormant when there is no insulin to press the switch.

All this is progress indeed, but questions remain to be answered. For instance, when receptors are isolated from most cell types they appear to be exclusively in the $\alpha_2\beta_2$ form and phosphorylation, which is presumed to take place within the tetramer on binding of insulin[5], requires no further aggregation. What then are we to make of the aggregates of Johnson *et al.*? Is it possible that EGF can modulate the cell's response to insulin by altering the association of the insulin receptors? Does phosphorylation or some other kind of interplay between heterotetramers control a later event in the insulin response? □

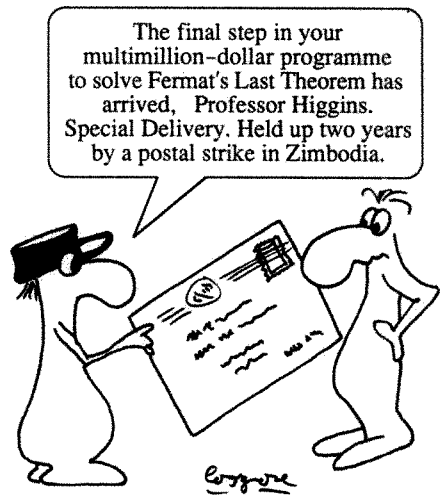
Computation

Highly distributed processing



Ian Stewart

WHAT is the best way to obtain raw computational power? A massive central supercomputer or a network of smaller machines? Both have their passionate devotees. A recent calculation in number theory has given a new meaning to the phrase 'distributed processing': it illustrates the possible advantages of a network for problems that can be broken into independent pieces. A 100-digit number, carefully screened for maximum difficulty, has been resolved into prime factors by the communal efforts of a dozen mathematicians in three countries using 400 separate computers simultaneously and communicating by electronic mail. The marathon calculation widely reported in the popular press (see *Nature* **335**, 658; 1988) was organized by Mark S. Manasse of the Digital Equipment Corporation's research centre at Palo Alto and Arjen K. Lenstra of the University of Chicago. It took less than a month: a supercomputer working non-stop would have taken at least a week and cost a great deal more.

The factorization of large numbers into primes used to be of purely theoretical interest. Today, however, the problem has important applications in cryptography and cryptanalysis. A well known method of encoding sensitive information, the RSA (Rivest–Shamir–Adelman) system, relies for its security on the conjectured difficulty of resolving an arbitrary number into its constituent primes. Any improvement in factorization methods is thus automatically of interest in a much wider sphere. The communal effort under discussion is in a sense most noteworthy for its *lack* of novelty. The actual method employed, known as the quadratic sieve, was invented by Carl Pomerance in 1982 (*Computational Methods in Number Theory Part I* (eds Lenstra, H. W. Jr & Tijdeman, R.) Mathematisch Centrum Tract **154**, Amsterdam; 1982), and was rapidly accepted as one of the fastest methods available.

The first thing to understand about prime factorization is that the most obvious method, trial division of the number N by each possible prime in turn up to the square root, is hopelessly inefficient for numbers with more than just a few digits. The number of primes less than $\sqrt{N}$ is approximately $2\sqrt{N}/\log N$, so the number of trials needed for a 100-digit number is roughly $2 \times 10^{50}/(50\log 10) = 1.7 \times 10^{48}$. At a million trials per second the computation would take about 5×10^{34} years, or at least 10^{27} times the age of the Universe. Variations on this technique, such as strategies for searching specific ranges of primes, like starting at $\sqrt{N}$ and working backwards, suffer from the same defect.

The solution is to apply more subtle methods, based on results in number theory. Suppose we wish to find the prime factors of a number N. If we can find just one of them, we can divide it out and repeat the process on the much smaller number that results. So the real problem is to find *some* prime factor. One approach is to look for two perfect squares whose

difference is a multiple of N. Let x^2 and y^2 be these squares. Because $x^2-y^2 = (x-y)(x+y)$, any prime factor of N must divide either $x-y$ or $x+y$. Suppose for the sake of argument that it divides $x+y$; then it also divides the highest common factor of $x+y$ and N. There is a very efficient method, known as the euclidean algorithm, for computing this highest common factor, which in general is much smaller than N. Because it is smaller, we can find its prime factors relatively easily; but these are also prime factors of N. The strategy is thus very much one of 'divide and conquer'.

It's a neat trick — but how do we find x and y? Michael Morrison and John Brillhart (*Mathematics of Computation* **29**, 183–205; 1975) realized that suitable candidates for x and y could be found by using the continued fraction for $\sqrt{N}$, a sequence of fractions p/q that approximate $\sqrt{N}$ ever more closely. Their proposal was to run along this sequence of fractions waiting for the denominator q to become a perfect square. When this happens, suitable x and y can easily be found. But there is a much better way. Instead of waiting for a square denominator to turn up, we can try to create one. Some upper limit is chosen and each denominator is checked to see whether all of its prime factors lie below this limit. If so, its factorization is stored as a sequence of zeros and ones: 0 if the corresponding prime factor occurs t even power, 1 if it occurs to an odd po In this way a huge matrix is built up, these sequences as its rows.

Some subset of all these denomina multiplied together, will form a squa provided that the corresponding s ences have, between them, an even n ber of ones in each column. This ca checked quickly by standard techni of linear algebra, known as gaus elimination. Having found a combina of denominators whose product is a fect square, numbers x and y such N divides x^2-y^2 are again easy to find. is the basic idea: the full-blooded quad sieve incorporates several further re ments, including strategies to cut shor computation if it is getting nowhere. detailed description see *Prime Num and Computer Methods for Factoriza* by Hans Riesel; Birkhäuser, Boston, 19

Manasse and Lenstra's collabora were from the United States, the Net lands and Australia. The matrix requ to apply the quadratic sieve turned ou have 50,000 rows and columns, a tot 250 million entries. The computatio the matrix was split into 400 pieces, results were assembled by electronic at Palo Alto, and the final gaussian el nation led to the discovery that the n ber had two prime factors, with 40 an digits. There are so many computers that much of their time is effectively f especially for low-priority jobs runnin background', and the tale bears dram witness to the capabilities of a networ small machines running in parallel.

The quadratic sieve is a highly refi and extremely clever technique, but by now become fairly standard. So sense the method is an example of br rather than brains. The particular styl brawn, large-scale international coop tion, is seldom applied in such an or nized manner. On the other hand, whole of mathematics is a large-s international cooperation, whose custo ary methods of communication are ofte good deal slower than electronic mail.

By pushing the present approach to limits, factorizations of 110- or perh 120-digit numbers might be achieved. factorize an arbitrary 150-digit numb say, still looks out of the question, the only hope is a completely new id This is not inconceivable; for exam Hendrik Lenstra (of Amsterdam Univ sity) recently suggested a new appro involving so-called elliptic curves (see News and Views article in *Nature* **325**, 1 1987), which can sometimes be extrem efficient. But no known method wo efficiently for the awkward cases as well the nice ones. In the world of prime f tors, nobody yet knows whether brain ultimately prove superior to brawn.

RNA processing

Splicing a spliceosomal RNA

David A. Brow and Christine Guthrie

Two fundamental questions that captivate the interest of those who study RNA processing are how interrupted genes acquired their introns and how the removal of introns from RNA is catalysed. Tani and Ohshima report on page 87 of this issue[1] a remarkable finding that may bear on both questions: they identify an intron within a gene encoding a spliceosomal RNA. The spliceosome is the structure responsible for removal of introns from nuclear pre-messenger RNA (Fig. 1). It is assembled from the pre-mRNA, four small nuclear ribonucleoprotein complexes (snRNPs) called U1, U2, U5 and U4/6, containing five small nuclear RNAs (snRNAs), and an as yet unknown number of additional proteins (see ref. 2 and the News and Views article[3] by M. R. Green). Because the intron discovered by Tani and Ohshima has the distinctive structure of nuclear pre-mRNA introns, it seems in this case that an snRNA is spliced by the very apparatus of which it is an important component.

The intron interrupts the single-copy gene encoding U6 snRNA in the fission yeast *Schizosaccharomyces pombe*, and contains perfect matches to the consensus sequences that have been identified at the splice sites and at the site of branch formation in nuclear pre-mRNA. Tani and Ohshima point out[1] that this strict adherence to the consensus motif, in an organism where these sequences are often rather divergent, suggests the U6 intron is under selective pressure for efficient removal. Indeed, Tani and Ohshima observe only fully spliced U6 snRNA *in vivo* under normal growth conditions. Although the participation of U6 in the removal of the U6 intron can as yet only be inferred, a consideration of the possible origin of this intron has interesting implications for the general role of U6 snRNA in splicing.

It is the snRNAs, rather than the proteins, that are believed by many to be the main catalytic elements of the spliceosome. This notion follows from the discovery of another class of RNAs, the group II self-splicing pre-mRNAs, in which excision of the intron and ligation of the remaining exons occurs via a pathway that is mechanistically very similar to that of nuclear pre-mRNAs, but does not require proteins[4,5]. Indeed, it has been suggested that the spliceosome evolved from such autocatalytic RNAs[6]. Thus, in the study of spliceosome-mediated intron removal, much effort is being directed towards attributing specific catalytic functions to the snRNAs.

U6 snRNA is by far the most highly conserved spliceosomal RNA[7], and so is expected to have a fundamental role in splicing. Yet, unlike the U1, U2 and (probably) U5 snRNA-containing snRNPs, which recognize the conserved intron elements (Fig. 1), the function of the snRNP containing U4 and U6 snRNAs is unknown. U4 and U6 are strongly associated with one another by base-pair interactions that form two contiguous stems (Fig. 2, stems I and II). Curiously, these stems lie within the most highly conserved segment of U6, consisting of 49 nucleotides with at least 80 per cent identity between yeasts and mammals. Normally, paired bases exhibit phylogenetic covariation, changing their identity but maintaining complementarity (for example, A–U changes to G–C). This paradox could be resolved by the surprising observation that the stable U4/6 interaction is disrupted during splicing *in vitro*, as judged by the loss of U4 from the spliceosome before or during the first nucleolytic step[8-10] (Fig. 1). Thus, the conservation of U6 within the stems could reflect an additional role for this region when it is unpaired. Indeed, the timing of U4 dissociation with respect to the generation of splicing products suggests that this highly conserved region of U6 may be involved in catalysis. U4 could thus be viewed as an anti-sense RNA that negatively regulates U6 activity.

The intron identified by Tani and Ohshima is located precisely in the middle of the highly conserved region of U6, bifurcating interaction stem I (Fig. 2). Its presence in a U6 gene is particularly surprising as this is the first example of a pre-mRNA-like intron in an RNA polymerase III transcript[11,12]. The fact that half a dozen

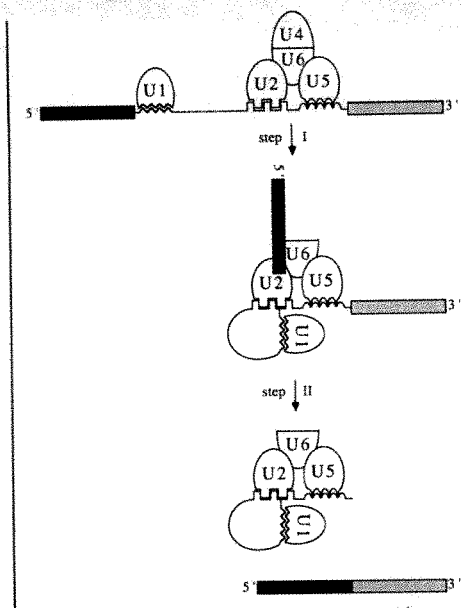

Fig. 1 Nuclear pre-mRNA splicing pathway. The 5′ and 3′ exons are represented as dark and light boxes, respectively, and the intron as a thin line. Top, fully assembled spliceosome, with U1, U2 and U5 snRNA-containing snRNPs interacting with conserved sequences at the 5′-splice site, branch point and 3′-splice site, respectively. Middle, during or before the first nucleolytic step of splicing, U4 dissociates from the spliceosome, which now contains free 5′ exon and the branched 'lariat' intermediate. Bottom, step II produces spliced mRNA and free intron lariat, still bound by snRNPs. (Contacts between snRNPs do not imply proven associations.)

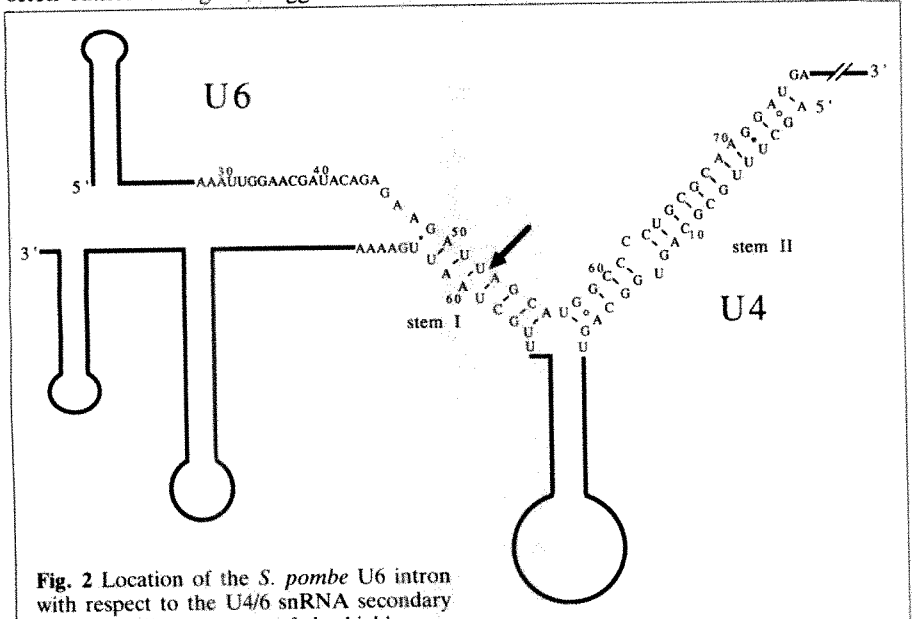

Fig. 2 Location of the *S. pombe* U6 intron with respect to the U4/6 snRNA secondary structure. The sequence of the highly conserved region of U6 (from mammals), and the region of U4 with which it pairs[7], are shown. Other stems are shown as adjacent parallel lines. Arrow, site equivalent to the *S. pombe* intron insertion site described by Tani and Ohshima[1].

other sequenced U6 genes (including two from the budding yeasts) contain no intron, together with the obvious 'chicken-or-egg' problem presented by an intron in a spliceosomal RNA, suggest that the intron was not present in the progenitor U6 gene, but may have been acquired more recently in evolution. Given that the U6 intron does not appear to be a transposable element[1], how did it arise?

An intriguing possibility is that the *S. pombe* U6 intron arose from a mishap during pre-mRNA splicing. Perhaps, during its excision from pre-mRNA, an intron inserted into the U6 RNA molecule present in the spliceosome. The resulting product was presumably reverse-transcribed and its complementary DNA then replaced the chromosomal U6 gene. If this scheme is correct, the site of intron insertion would probably reflect the proximity of that part of U6 to the catalytic centre of the spliceosome. The picture of U6 that emerges is of a central, possibly catalytic site flanked by conserved sequences positioned to interact, directly or through other snRNPs, with the pre-mRNA near the 5′ and 3′ splice sites.

Insertion of an excised intron into RNA is not unprecedented: it has recently been found that autocatalysed splicing of a group I pre-ribosomal RNA (which proceeds by a mechanism somewhat different from that used by the group II and nuclear pre-mRNA introns[6]) can run backwards, with the intron reinserting at the site of its excision (S. Woodson and T. Cech, personal communication). Although the origin of the intron discovered by Tani and Ohshima is a matter for conjecture, a significant step in advancing these ideas from the realm of speculation may come from further sequence analysis. Identification of an intron at the same site in the U6 gene of an organism unrelated to *S. pombe* would support the proposed mechanism of insertion and its implications for U6 function. □

Submillimetre astronomy

Different views of the Universe

Glenn J. White

ONE of the few remaining unexplored regions of the electromagnetic spectrum accessible to ground-based astronomical observations lies at wavelengths between 1 and 0.3 mm. Using the new generation of large submillimetre-wave telescopes which have recently been completed in Hawaii, Europe and Chile, astronomers have been actively studying a wide range of astrophysical problems related to the Solar System, the physics of star formation, the chemical and dynamical evolution of the interstellar medium, the structure and evolution of galaxies, and the nature and energetics of active galactic nuclei and quasars. This spectral region is well suited to the study of gas and dust in the interstellar medium, particularly in its ability to sample regions which are highly opaque at optical wavelengths. The first results from these new telescopes, especially those relating to the interstellar medium, were discussed at two recent meetings*.

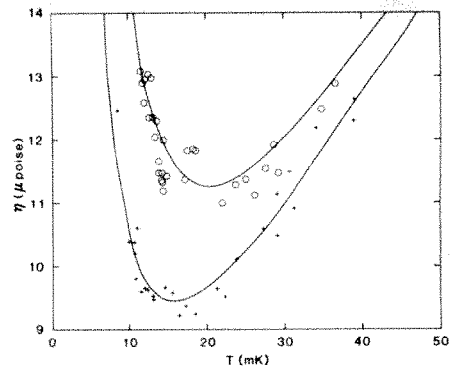
An accurate determination of the mass of material in the interstellar medium is crucial to many astrophysical studies, including those of the structure and dynamics of molecular clouds and their subsequent formation of stars. Most of this mass is in the form of hydrogen, which remains very difficult to observe from the surface of the Earth. Consequently it is necessary to infer its presence from observations of other molecules such as carbon monoxide, which undergo frequent collisions with it. These collisions excite rotational (J) transitions in the molecular species, which are observable throughout the millimetre and submillimetre wavelength part of the spectrum. As part of the continuing controversy about the $N(H_2)/W(CO)$ ratio (column density of H_2 over integrated intensity in the CO $J=1$–0 transition) in interstellar gas in our Galaxy and external galaxies, new observations indicate that the value of this ratio is about six times larger in the Large Magellanic Cloud than in our own Galaxy (T. Dame, Harvard–Smithsonian Center for Astrophysics), and up to 25 times larger in the Small Magellanic Cloud (M. Rubio, Harvard–Smithsonian Center). To explain these discrepancies, it was suggested that scattering of CO radiation in the low-density envelopes of clouds may in part account for the discrepancies between $N(H_2)$ determinations from CO, ^{13}CO and $C^{18}O$ in galactic clouds (M. Guélin, Institut Radio Astronomie Millimétrique).

In addition to the hydrogen gas, about 70 other molecular species have been detected in the interstellar medium as minor constituents. These are subject to a complex range of chemical interactions, which also influence the thermal balance of the gas and ultimately the structure and stability of molecular clouds. With the extremely high angular and spectral resolution now available in the millimetre and submillimetre wavelength region, detailed studies are possible which trace variations of both chemistry and excitation throughout molecular clouds. New evidence shows that ultraviolet radiation can penetrate interstellar clouds to a much greater extent than previously realized, because of the clumpy nature of material in molecular clouds. This can lead to an increase in the rate of photodissociation of the molecules, and modification of the local chemical equilibrium. These results, based on submillimetre wavelength observations of C I and C II (neutral and singly ionized carbon) emphasize the increasing importance of high-frequency observations (J. Stutzki, Max Planck Institut für Astrophysik, Garching).

One important consequence of this higher radiation field is to speed up the chemical processing and evolution of molecular clouds (W. Langer, Princeton University). The models, however, are still unable to explain all the recent observational estimates of the abundances of various molecules. Consequently, the importance of time-dependent gas-phase chemistry (E. Herbst, University of Cologne), and grain-surface reactions, particularly for hydrogenated amorphous carbon (W. Duley, York University) were discussed to account for the long-chain hydrocarbon molecules observed in regions like the Taurus molecular cloud.

After the gravitational collapse of a molecular cloud, stars may ultimately be born out of the gas, with some of the residual debris going on to form 'planetary' systems. Although it is perhaps remarkable that ground-based observations of rather 'average' stars in the Galaxy can still hold many new surprises, recent observations have confirmed the presence of dust shells around stars such as Vega, α PsA and β Pic (E. Becklin, University of Hawaii). The submillimetre wavelength fluxes, however, fall well below those predicted from an extrapolation of the Infrared Astronomical Satellite (IRAS) measurements, suggesting that the particles are mostly less than 100 μm diameter. The most likely explanation is that they have been generated since the formation of the star, probably as a consequence of cometary or asteroid collisions.

For molecular clouds to collapse to form stars, a delicate balance between



* *The Physics and Chemistry of Interstellar Molecular Clouds*, Zermatt, 22–25 September 1988 and *Millimetre and Submillimetre Astronomy*, Kona, Hawaii, 3–6 October 1988.

their internal pressure and the opposing force of gravity regulates the rate at which stars will be formed. Until recently it has been extremely difficult to estimate the strength of magnetic fields inside dense regions, although this has now become possible at millimetre and submillimetre wavelengths, in particular by measuring the amount of polarized radiation emitted from the interstellar dust. Measurements of the magnetic fields in several molecular clouds suggest that the magnetic contribution to the internal motions and energy of many of these clouds is crucial for cloud dynamics, cloud evolution and star formation (P. Myers, Harvard–Smithsonian Center; R. Hildebrand, University of Chicago). In addition it has been suggested that hydromagnetic waves may be responsible for inducing density fluctuations throughout the interstellar medium (R. Pudritz, McMaster University), and examples of large-scale filamentary and ordered structures can now be seen in extensive maps of regions such as the Orion molecular complex (J. Bally, AT&T Bell Laboratories). The size scales of these large structures, which can extend over many tens of square degrees on the sky, emphasize the unique role which can be played by small telescopes, whose large beams make it possible to map extensive areas of the sky rapidly (P. Thaddeus, Harvard–Smithsonian Center).

The Galaxy is a large place, and it remains difficult to build up a detailed view of the large-scale processes occurring during stellar formation. However, the physics of star-formation across a whole galaxy can be uniquely viewed in nearby face-on spiral galaxies. Using a millimetre wavelength interferometer, new observations of M51 have been made which reveal the presence of giant molecular complexes having sizes of around 400 parsecs and masses greater than 10^7 solar masses. The velocity structure of the molecular material shows systematic gradients across individual galactic spiral arms, where the star formation efficiency is also found to be strongly enhanced. This suggests that density waves are responsible for triggering star formation on a galactic-wide scale (S. N. Vogel, Rensselaer Polytechnic Institute: see Vogel, S.N., Kulkarni, S.R. & Scoville, N.Z. *Nature* **334**, 402–406; 1988).

The millimetre and submillimetre wavelength regions are important to the study of objects such as ultraluminous galaxies. These objects, first detected by IRAS, may in some cases go on to form quasars. Using a synthesis of recent results and new observations in the CO line, it was suggested that the collision, or merger, of two spiral galaxies, can result in removal of angular momentum and allow an infall of gas towards their centres. This rapid accretion leads to a star burst in the nucleus, and then the aggregation of gas and stars into a massive central stellar cluster. The subsequent nucleation of this core, and a continued infall of material from the outer parts of the merger may lead on to the formation of an active galactic nucleus or quasar (N. Z. Scoville, California Institute of Technology). □

Measurements of the viscosity η of a 0.1-per-cent ^{3}He–^{4}He solution as a function of temperature T in zero magnetic field (+) and in a magnetic field of 10 tesla (○). The lower solid curve represents a fit of theory to the data with the strength of the interaction between the ^{3}He atoms as an adjustable parameter; the upper curve is a prediction by the same theory without any further adjustable parameters. (From Owers-Bradley *et al.*.)

Low-temperature physics

Viscosity of ^{3}He–^{4}He solutions

P.V.E. McClintock

Liquid helium thickens slightly when subjected to a strong magnetic field at very low temperatures. The latest measurements of this intriguing effect, which occurs only in liquid ^{3}He–^{4}He isotopic mixtures or in pure liquid ^{3}He, are reported in a recent issue of *Physical Review Letters* (**61**, 1619–1622; 1988) by J.R. Owers-Bradley and colleagues at Nottingham University.

The new experiments were performed on a dilute solution containing 0.1 per cent of the rare helium isotope ^{3}He dissolved in the common isotope ^{4}He. The properties of liquid ^{3}He and liquid ^{4}He at low temperatures are markedly different, and a solution of this kind is a rather strange material. Liquid ^{4}He, a so-called boson system in which there is no restriction on the number of particles that may occupy any given energy state, becomes superfluid below a temperature of 2.17 K: it loses all its viscosity and objects can move through it without experiencing the drag found in conventional liquids.

Liquid ^{3}He, on the other hand, is a fermion system in which there is a rigorous restriction that forbids more than one particle from simultaneously occupying any given energy state. (It too becomes superfluid, but must be a thousand times colder before the transition occurs.) When dissolved in ^{4}He, ^{3}He atoms move effortlessly through the superfluid. In fact, the superfluid ^{4}He just constitutes a kind of ethereal background, often termed a mechanical vacuum. The ^{3}He atoms in it form an almost ideal gas and, for most purposes, the presence of the superfluid background can be ignored.

Because of the restriction on the occupation of energy states, it is characteristic of fermion systems that they possess a great deal of energy, even at 0 K. The system tries to get into the lowest allowed energy configuration, which means that every permitted state is occupied from zero up to a maximum energy known as the Fermi energy, E_F; all states above E_F are empty. The magnitude of E_F depends on the density of fermions and, in the case of a ^{3}He–^{4}He solution, can conveniently be adjusted simply by changing the concentration of ^{3}He.

The ^{3}He nuclei carry tiny magnetic moments which, according to quantum mechanics, align either with or against an applied magnetic field, the two alignments having different energies. When a magnetic field is first applied to the cold liquid, half of the ^{3}He atoms suddenly have their energy increased relative to the other half so that, in effect, each group momentarily has a different Fermi energy. Relaxation processes then occur in which some of the higher-energy atoms make transitions to the lower-energy aligned states, until the value of E_F is again common to both groups. The liquid becomes polarized, there being more atoms aligned with the field than against it. At sufficiently low temperature, the degree of polarization achievable by this 'brute force' method depends on the relative magnitudes of the magnetic and Fermi energies. By using a dilute ^{3}He–^{4}He solution, making E_F relatively small, Owers-Bradley *et al.* obtain a much higher degree of polarization in a given magnetic field than was the case in the earlier experiments of, for example, G.A. Vermeulen *et al.* (*Phys. Rev. Lett.* **60**, 2315–2318; 1988) using pure liquid ^{3}He.

Because the interactions between pairs of ^{3}He atoms depend on whether their nuclear magnetic moments are parallel or antiparallel to each other, the properties of a polarized ^{3}He–^{4}He solution are expected to differ markedly from those of an ordinary unpolarized one. The interaction is stronger between pairs of atoms whose moments are antiparallel, and these

obviously become fewer as the solution polarizes. The mean free path of the atoms consequently increases with polarization, generating corresponding changes in the transport coefficients, including an increase in viscosity. From the measured magnitude of the change in viscosity it should be possible to derive parameters of the interaction between the ^{3}He atoms.

Following a technique described by D.S. Greywall and M.A. Paalanen (*Phys. Rev. Lett.* **46**, 1292–1295; 1981), Owers-Bradley *et al.* used measurements of second sound — a density wave in the gas of ^{3}He atoms — to deduce the viscosity. They investigated standing waves of second sound in a resonant cavity and, after making appropriate allowance for other dissipative processes, determined the viscosity of the liquid from the measured widths of the resonances. The results (see figure) show clearly that the viscosity increases on application of the field, the increase becoming substantially larger as the temperature is reduced. The results should be more accurate and reliable than the earlier ones of Greywall and Paalanen who worked with a resonator which produced a distorted line shape owing to a hole in the cavity wall needed to assist cooling of the sample inside. In the new resonator, the inner wall is made of sintered silver, whose large surface area allows the sample to be cooled directly without any need for a hole to the exterior refrigeration arrangements.

An interesting feature of the results is that, unlike in an earlier experiment by D.A. Ritchie *et al.* (*Phys. Rev. Lett.* **59**, 465–468; 1987), there seems to be no evidence of 'slip' at the walls: rather, there was a boundary layer of effectively stationary ^{3}He at the walls, as would be expected with an ordinary viscous fluid. The authors suggest the difference may arise because Ritchie *et al.* used a smooth-walled chamber, quite different at the microscopic level from the rough, porous, sintered silver walls of the present experiment.

The lower curve of the figure represents a fit of a theory, based on ideas originally developed by E.P. Bashkin and A.E. Meyerovich (*Adv. Phys.* **30**, 1–92; 1981), to the zero-field viscosity measurements, using the strength of the interaction between the ^{3}He atoms as an adjustable parameter. The agreement is excellent and in itself suggests that the deduced form of the interaction is probably correct. The real test, however, is seen in the upper curve which is a prediction of the behaviour at 10 tesla without recourse to any additional adjustable parameters. Again, the agreement is excellent, apparently confirming the validity both of the theory and of the interaction deduced by fitting it to the zero-field data. □

Sickle cell anaemia

A simple disease with no cure

L. Luzzatto and P. Goodfellow

MOLECULAR biology has explained the basic defect in sickle cell anaemia and has provided the tools for prenatal diagnosis, but the treatment of afflicted patients undergoing crisis has not correspondingly improved. For the pessimist, this fact poses the general question of the efficacy of molecular approaches for treatment of genetic disease; and this echoes previous debates about the reductionist approach of molecular biology. Be that as it may, a positive step was taken by the Wellcome Trust in the sponsoring of a Sickle Cell Workshop, held in London on 4 November 1988, to consider new approaches to the treatment of sickle cell anaemia.

No genetic disease could be simpler than sickle cell anaemia. A single base pair in the β-globin gene is mutated from adenine to thymine producing a corresponding change in the sixth amino acid of the protein from glutamic acid to valine. Under conditions of low oxygen tension, the abnormal deoxyhaemoglobin polymerizes and eventually leads to a change in red blood cell shape termed sickling. When distorted red blood cells occlude small blood vessels, this can result in 'crisis', a term that dramatically describes a wide spectrum of events, from relatively brief painful episodes to massive thrombosis leading to infarction in bone, lung or brain. The organ damage is potentially crippling and the crisis may be life-threatening.

Following the theme of "know your enemy", G. Serjeant (MRC Laboratory, Jamaica) described the natural history of sickle cell anaemia. The trigger for crisis is not clear, but its onset is often associated with a drop in environmental temperature (Redwood, A.M. *et al. Br. med. J.* **i**, 66; 1976). Exposure to cold may divert blood flow from the bone marrow, causing local necrosis and 'bone' pain. Exploration of this hypothesis will require quantitation of the environmental factors triggering crisis and measurements of blood flow to the bones of patients suffering crisis. The entire physiology of the microcirculation in bone and bone marrow requires investigation, especially because the rheology of blood is affected by the presence of sickled cells and also by the numbers of white cells (I. Smaje, Wellcome Trust), which are often increased during crisis.

Although all patients with sickle cell anaemia have exactly the same genetic defect, there is wide variation in clinical expression of the disease. D. Weatherall (Oxford University) considered genes that modify the phenotype. Some of this variation results from the coexistence of a deletion in another globin gene, α-thalassaemia (see Dover, G.J. *et al. Blood* **69**, 341; 1987). Thus a typical mendelian disorder has some of the features of a polygenic disorder. Other hypothetical compensatory mutations may affect the intraerythrocytic level of diphosphoglycerate (DPG), the main physiological regulator of the oxygen–haemoglobin dissociation curve. In other chronic anaemias, an increase in DPG levels improves oxygen delivery to tissues (Torrance, J. *et al. New Engl. J. Med.* **283**, 165; 1970); but in sickle cell anaemia this adaptive response backfires because the extra deoxygenation of haemoglobin favours sickling. Another component favouring sickling could be a *p*H-dependent ouabain-insensitive potassium channel that is apparently more active in the young red cells of sickle cell anaemia patients (C. Ellory, Oxford University). This channel may contribute to dehydration of red blood cells and the consequent promotion of irreversibly sickled cells. Both this potassium channel and the enzyme diphosphoglycerate mutase, which regulates the DPG level, are potential targets for drug therapy.

Treatment strategies can be broadly divided into five categories: anti-sickling agents; vasoactive drugs; promotion of persistence of fetal haemoglobin; bone marrow transplantation; and gene therapy. The first three approaches have failed so far, but there is increasing interest in the last two. Transplantation is available only to patients who have a suitable sib donor and the risks associated with the procedure and with graft-versus-host disease are still too high for this approach to become generally applicable in the treatment of sickle cell anaemia. But it is worth noting that bone marrow transplantation has been used successfully to treat about 200 children suffering from the more severe anaemia, thalassaemia major.

Gene therapy would avoid the problems associated with transplant rejection and graft-versus-host disease. Two approaches can be envisaged: replacing the mutated β-globin gene by homologous recombination; or insertion into the genome of haemopoietic cells of an additional copy of the normal gene. The ideal approach is the former, but it requires a substantial improvement in the isolation and culture of pluripotent stem cells as well as in the efficiency of homologous recombination. The second approach also requires technical advances in stem cell culture and the development of suitable

gene-transfer methods. In the meantime, the recent identification of a control element 60 kilobases upstream of the β-globin gene (F. Grosveld, National Institute for Medical Research, London) has solved the problem of obtaining high-level, tissue-specific expression of human β-globin in transgenic mice. Nevertheless, if gene therapy is going to be a cure for sickle cell anaemia (and many other diseases), a serious investment of resources must be made in this area.

Sickle cell anaemia has always been the paradigm for molecular analysis of genetic disease and the disappointing progress in treating it could be a warning for those studying other diseases. As is clear from the example of sickle cell anaemia, avoidance of this fate will require continued studies on the natural history of diseases and the physiological interactions in the whole organism: perhaps a true anti-sickling agent will then turn up.

The development of novel treatment strategies could be greatly facilitated by animal models, and it would seem to be a high priority to adopt the new techniques of embryonic stem cell manipulation to create a mouse model of sickle cell anaemia (see Rubin, E.M. *et al. Am. J. hum. Genet.* **42**, 585; 1988). In some cases, mutations in the mouse models have failed to mimic directly the human disease. Notable examples include deficiency of the enzyme HPRT for Lesch–Nyhan disease and the *mdx* mouse models for Duchenne muscular dystrophy, respectively. But this serves only to emphasize the importance of physiological studies and provides an opportunity for discovering key steps in the disease process. Finally, if somatic gene therapy is going to be a viable approach for treatment of genetic disease, much more must be learned about the biology of stem cells, be it in muscle, brain or bone marrow. □

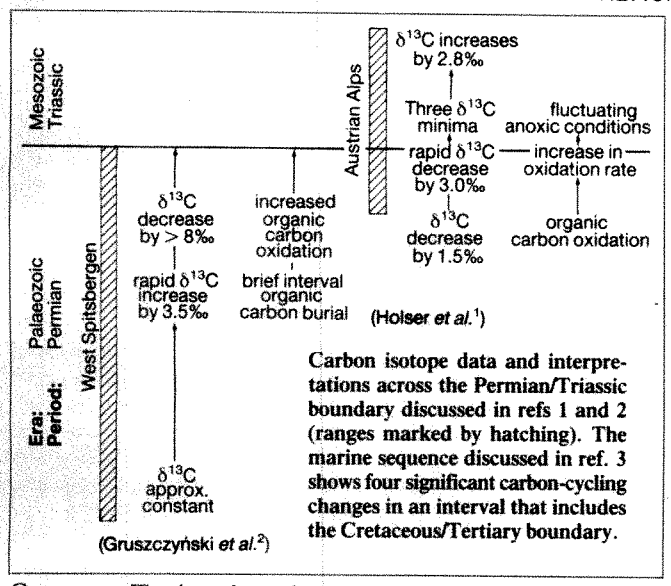
Geological boundaries

Extinctions and carbon cycling

M.L. Delaney

ARE mass-extinction events causes or consequences of changes in global carbon cycling? Reports on marine sequences by Holser *et al*[1], Gruszczyński *et al.*[2] and Zachos *et al.*[3] on pages 39, 64 and 61, respectively, of this issue conclude that substantial shifts in carbon partitioning among and within major sedimentary reservoirs occurred before, during and after extinction events defining the boundaries of the Mesozoic era. But the nature of carbon cycling associated with these mass extinctions, as recorded in the oceanic carbon istope composition, is unique to each boundary. The Permian/Triassic mass extinction, about 250 million years ago (Myr), followed a prolonged interval of greatly increased net organic carbon oxidation. By contrast, the Cretaceous/Tertiary extinction (about 66 Myr) apparently resulted in the rapid cessation of oceanic primary productivity. After both boundaries, despite their different natures, recoveries of oceanic carbon isotope systems to more typical conditions took a substantial time.

Organic matter, formed in oceanic surface waters where light and nutrients are available for primary productivity, has a lower ratio (by about 2 per cent) of the rare, heavier stable carbon isotope (^{13}C) to the more abundant one (^{12}C) than the dissolved inorganic carbon. Therefore, dissolved inorganic carbon in surface waters, where organisms have used most of the available dissolved nutrients and preferentially taken up the lighter carbon istope, is relatively enriched in ^{13}C. The ^{13}C-depleted organic matter falls through the water column and is recycled back to its dissolved, inorganic constituents at depth, giving the dissolved inorganic carbon in deep waters a relatively low ratio of ^{13}C to ^{12}C. This surface-to-deep difference in the ratio of the two forms of carbon is thus generated by the cycle of primary production in surface waters and organic matter regeneration in deep waters. Consider a case where primary productivity in surface waters was greatly reduced (while nothing else about the ocean changed); $^{13}C/^{12}C$ ratios in surface and deep waters would become more similar, with the surface-to-deep gradient in carbon isotope ratio reduced.



Over longer timescales, the important carbon sources and sinks for the ocean as a whole are weathering of material from and burial of material into two sedimentary reservoirs: organic carbon, relatively depleted in the heavier isotope, and calcium carbonate, relatively enriched. Estimates are at present that the burial rate of carbon in the carbonate sink is four times that in the organic carbon sink. The average ratio of the two carbon isotopes in the ocean at any time reflects the balance of these geological cycles. For example, an increased supply to the ocean of carbon from organic carbon weathering, all else being equal, would result in a lower ratio of ^{13}C relative to the lighter isotope in the ocean overall.

Surface-to-deep carbon isotope patterns can be studied by comparing the carbon isotope ratios in the calcite shells of surface and deep-dwelling organisms, as this material forms with little difference between its carbon isotope ratio and that of dissolved inorganic carbon. Long-term changes in carbon cycling affecting the ocean, such as decreases in organic carbon burial or increases in weathering, can be monitored by the ratio of the two carbon isotopes in shell material or in bulk carbonate sediments, reflecting the oceanic inventories of the two isotopes. Mass extinctions should result in dramatic decreases in primary productivity, and thus in carbon cycling within the ocean and relative to its sources and sinks[4]. The surface-to-deep gradient in ^{13}C to ^{12}C should be greatly reduced and the ratio of ^{13}C to ^{12}C in the ocean should decrease temporarily. The decreased surface-to-deep carbon isotope ratio has been previously noted for several Cretaceous/Tertiary boundary sequences, and a negative carbon shift has been observed for both of these extinction boundaries. The contributions[1-3] discussed in this article make clear the complexity of these transitions and the extended nature of the changes in oceanic carbon cycling, as recorded in carbon isotope records (see figure).

Holser *et al.*[1] present a detailed carbon isotope record from a continuous marine sequence in the Austrian Alps spanning the Permian/Triassic boundary, the most dramatic extinction event in the Phanerozoic. They conclude that this boundary was preceded by at least several million years of net oxidation of global reservoirs of organic carbon, and was followed by several anoxic episodes resulting from the long-term increase in the oxidation of organic carbon. The identification of these episodes of anoxia is supported by iron, sulphur and other minor-element data. But whether anoxia occurred globally or locally is unclear without data from other locations. The recovery to more typical carbon isotope values, and presumably to more normal oceanic oxidation–reduction conditions, took at least a few million years, indicating the complexity and long duration of this transition.

Gruszczyński *et al.*[2] use a carbon isotope record from brachiopod calcite from West Spitsbergen (present-day Arctic Ocean) to argue that the late Permian had a relatively brief interval of greatly increased organic-carbon burial before the start of the record presented by Holser *et al.* . The subsequent carbon isotope decline in their composite record is the largest yet observed in the late Permian. They suggest that the increased oxidation of organic carbon may have affected oceanic nutrient and atmospheric oxygen levels sufficiently to result in the mass extinctions.

Zachos *et al.*[3] conclude that the

Carbon isotope data and interpretations across the Permian/Triassic boundary discussed in refs 1 and 2 (ranges marked by hatching). The marine sequence discussed in ref. 3 shows four significant carbon-cycling changes in an interval that includes the Cretaceous/Tertiary boundary.

Cretaceous/Tertiary boundary was preceded by an interval of around 200,000 years of reduced net organic-carbon fluxes to the ocean. The boundary itself is marked by an extremely rapid cessation of oceanic primary productivity over less than 10,000 years, consistent with a bolide impact cause for these extinctions and apparently not related to the preceding shift in carbon isotopes. The drastic reduction in primary productivity persisted for at least half a million years at this low-latitude North Pacific site, with carbon isotope gradients between the surface and deep ocean not recovering to fully normal until about a million years after the boundary. This interpretation of these primary-productivity changes is enhanced by records of calcium carbonate accumulation and preservation and barium accumulation (as a proxy for organic carbon) at this site. Confirmation of the ocean-wide duration and intensity of these events requires more widespread geographic sampling of marine sequences spanning this boundary.

These three reports suggest intriguing links between carbon cycling and extinction events, with both events influenced by and resulting in changes in organic carbon cycling. Sea level seems to exert an important control on net rate of carbon oxidation and burial, with regressions favouring oxidation over burial[1,3]. Better knowledge of the relationship between sea level and carbon cycling, along with unambiguous records of sea level, is required to document the impact of sea level changes.

There is a limit to what records of oceanic carbon isotope composition, used so effectively in these reports, can reveal about mechanisms and results of extinction events. As discussed above, the distribution of carbon between carbonate carbon and relatively ^{13}C-depleted organic-carbon sedimentary reservoirs controls the average oceanic carbon isotope ratio, with the surface-to-deep gradient determined by organic-carbon formation and regeneration. Dissolved phosphate, a critical, limiting nutrient supplied to the oceans by continental weathering, is incorporated in organic matter in primary productivity and recycled back to the dissolved state by organic matter regeneration in deep waters. Surface waters have relatively low dissolved phosphate concentrations, therefore, and deep waters are phosphate-enriched.

Net organic-carbon burial in the sedimentary reservoir is an important sink for phosphate, estimated to account for 40 per cent of the total removal at present. Organic carbon is thus an important phosphorus carrier in the water column and an important removal mechanism for phosphorus from the oceans; any carbon cycling change has to affect oceanic phosphate inventories and distributions. For example, the marked decline in primary productivity inferred at the Cretaceous/Tertiary boundary should result in a more uniform water-column distribution of phosphate concentrations. The increased phosphate concentrations in surface waters, considered alone, should in turn result in increased rates of primary production, which would tend to re-establish the water column phosphate gradient.

Also, the increased weathering of organic carbon before the Permian/Triassic boundary probably would have resulted in increased phosphate inputs to the ocean. These increased phosphate inputs should result in higher rates of primary productivity in the water column, if oceanic turnover times were similar. This in turn could result in higher rates of organic-carbon burial, negating the effects on the carbon isotope composition of increased weathering. Obviously, the mechanisms relating phosphate inventories, carbon isotopes and primary productivity are more complex than these simple examples. Carbon-isotope signatures alone cannot reveal linked changes in oceanic nutrients and primary productivity. Geochemical tracers indicating nutrient concentrations and productivity variations are needed to unravel oceanic carbon cycling changes around extinctions; Zachos *et al.*[3] take a first step by using barium fluxes as indicative of organic-carbon fluxes. Ultimately, because organic-carbon weathering and burial influence atmospheric carbon dioxide and oxygen levels[4,5], an understanding of the links between these cycles will help to quantify atmospheric changes which can influence climatic changes. □

RNA structure

Unwinding with a vengeance

Robert A. Lamb and Gideon Dreyfuss

UNTIL very recently, the old rule was that by examining the sequence of the genome template the RNA product could be predicted. The new rule is that the old rule is not quite good enough any more. In the past two years, a plethora of findings have underscored the tremendous plasticity of RNA molecules and the amazing variety of reactions they undergo. Recent examples include the two apolipoprotein B messenger RNAs, one of which has a uridine (U) residue instead of a templated cytidine (C)[1,2]; the extensive addition of non-templated U residues to kinetoplastid mitochondrial mRNA in trypanosomes[3]; and the addition of two non-templated guanosine (G) residues to a paramyxovirus mRNA[4]. Now, in the 23 December issue of *Cell*[5], Bass and Weintraub report a striking addition to this new collection of modifications that change RNA structure. These investigators have discovered that a previously known[6–8] ATP-dependent unwinding activity also covalently modifies double-stranded RNA substrates by converting adenosine (A) to inosine (I) residues. This modification weakens the capacity for base-pairing and brings about essentially irreversible separation of the strands.

Other double-stranded (ds) RNA unwinding activities, both ATP-independent (for example, ref. 8; and several pre-mRNA proteins, see below) and ATP-dependent (such as the eukaryotic elongation factor eIF-4A, ref. 9) have been described in many organisms, but so far none of them has been shown also to involve modification of the RNA. As such, this novel activity described by Bass and Weintraub[5] accomplishes the task with a vengeance, as the change to the structure and composition of RNA is both profound and irreversible.

The dsRNA unwinding/modifying activity was detected by careful but

serendipitous observations during studies on anti-sense RNA. What might be the normal purpose of this irreversible process? The most obvious answer might be an antiviral defence mechanism. All RNA viruses have to go through a dsRNA intermediate in their life cycle. Although it is well established that one general defence response triggered by the dsRNA form is the induction of interferon, the unwinding and irreversible modification of RNAs that are in a dsRNA form could complement the interferon effects. But does this in fact happen?

It is conceivable that the footprints of an antiviral dsRNA unwinding/modifying activity may have been left with unexpected and disastrous consequences, and may even have caused a human disease. Measles virus, a member of the paramyxovirus–morbillivirus family, has a negative-stranded RNA genome that is transcribed in the cytoplasm by the virion RNA transcriptase into a series of positive-strand mRNAs. In very rare cases of measles virus infection, a persistent infection occurs that is thought to involve defects in functions related to viral assembly, but not to RNA replication. This can lead to subacute sclerosing panencephalitis (SSPE), a progressive disease of the central nervous system.

Recently, Cattaneo *et al.*[10] reported nucleotide-sequencing studies on cloned mRNAs isolated from autopsy material of SSPE brain. In one case they found that a discrete measles virus mRNA, whose protein product (M protein) is essential for virus assembly, has more than 50 per cent of its U residues changed to C. Although biased hypermutation caused by infidelity of the viral RNA transcriptase while transcribing only the M gene cannot be excluded as a mechanism for this[10], it now seems plausible that the establishment of the persistent infection that led to SSPE results from the newly described dsRNA unwinding/modifying activity. If, during transcription of the viral genome, the M gene mRNA fails to leave the template, the dsRNA unwinding/modifying activity could change the A residues on the template RNA to I. In the next round of transcription of mRNA these I residues are copied to C residues. This two-step conversion mechanism could explain the extensive U to C changes found in the mRNA. It should be emphasized that this is not the sole explanation for persistent infections of measles virus. But the strong mutagenic potential of the dsRNA unwinding/modifying activity may have far-reaching consequences.

Another possible function of this novel activity could be its capacity to change specific RNA molecules, or groups of RNA molecules, including mRNAs. This could be accomplished by expression of complementary RNAs (such as small-nuclear RNAs) either to specific regions within introns of pre-mRNAs, which could lead to alternative splicing patterns, or by modifications within the exons to bring about changes in the coding specificity. For example, a complementary small RNA that base-pairs to a region of an intron of a pre-mRNA which specifies its splicing pattern could stimulate the dsRNA unwinding/modifying activity to alter the relevant sequence such that it alters its normal splicing pattern. It is also possible that the activity found so far is merely one of many such activities and that other related ones with greater specificity lead to changes such as that found in the apolipoprotein B mRNA[1,2]. Perhaps the activity is a general way of ensuring that segments of RNA that have the tendency to form double-stranded structures (intra- or inter-molecular) are maintained in single-stranded form. Should this not be reason for those in the field to look for inosine in their RNAs?

What could regulate dsRNA unwinding/modifying activity and prevent it from modifying most RNAs in the cell? Two general categories of regulation can be considered. First, there may be specific regulatory components that interact with it but which were separated from it during fractionation. Second, there probably exist activities that can counter the unwinding component of the activity, such as annealing–promoting proteins and proteins that block and protect regions of dsRNA from dissociation. A potent annealing activity has recently been described in nuclear extracts[11]. Furthermore, RNA molecules exist in cells as RNA–protein complexes with RNP proteins. The recent finding of a complex assortment of RNA-binding proteins in pre-mRNA RNP complexes is an illustration of the abundance and diversity of RNP proteins[12]. Many of them, being RNA-binding proteins[12], can function in unwinding and annealing of RNA molecules, and can bind to specific RNA sequences[13], perhaps protecting them, and thus decisively influence RNA structure. Taken together with the sequence of the RNA itself, the interplay among all these factors will determine the structure and thereby the function of RNA in the cell. □

Daedalus

Fictitious fat

As many would-be slimmers know, the body has a preferred weight which it defends stubbornly. Even if forced to unload fat, it does so in a specific sequence, which (as in the case of the dreaded 'pear-shape syndrome') may not correspond to the desires of the slimmer. An adult body has a fixed number of fat cells; a successful slimmer succeeds in emptying some of them, while others nearby remain full. This, says Daedalus, makes good chemical sense. A droplet of fat in a cell is potentially metastable. If metabolic demand begins to shrink it a bit, its radius will decrease, its internal pressure will rise, its free-energy balance will shift towards further shrinkage, and the process will accelerate until the droplet is completely metabolized. So a fat cell can have only two stable states, full and empty. It is in fact a digital information-storage element. And this, says Daedalus, is how the body knows how heavy it is. Even within a fat deposit, the cells fill up in a preferred sequence, and it need only record the position of the currently active cell to know how far the process has got. This 'full up to here' signal is presumably relayed by the nerve connection from the cell.

This theory explains the digital accuracy with which some people maintain a steady weight despite their chaotic eating habits. It also suggests a new, powerful, and effortless way to lose weight. You merely generate a false 'full up to here' signal, suggesting to the body that a specific fat deposit is far fuller than it really is. It will then shed fat from that deposit, in an effort to restore the proper apparent loading.

So DREADCO volunteers are being gorged on a wildly calorific diet, and subsequently starved back to normal weight, while an NMR tomographic-imaging system maps the preferred sequence of filling and emptying of their fat cells. Daedalus will thus locate the last cell to be filled in each fat deposit. A false 'full up to here' signal from this cell would imply that the deposit is utterly full. So mild electric shocks at this exact location should induce rapid and effortless slimming. Indeed, a commercial shock-slimming system, claimed to work by stimulating the muscles, probably owes its sporadic success to this effect. But DREADCO's version will launch its false signals with reliable accuracy, giving far more dramatic results. Conversely, a false signal launched from the first-filled cell of a fat deposit will cause that deposit to gain weight.

Thus DREADCO's Programmed Electric Body Sculpture will reshape the user's fat deposits under full control. The pear-shape syndrome will be banished forever!

David Jones

Seal vaccination success

SIR—In providing evidence that the primary cause of the epizootic of distemper with high mortality among harbour seals (*Phoca vitulina*) in the North and Baltic seas was canine distemper virus (CDV) or a closely related morbillivirus[1], which has since been claimed to be a new morbillivirus christened phocine distemper virus (PDV)[2,3], we heralded our evaluation in seals of a subunit CDV vaccine, shown to be effective in dogs[4]. If seals can be protected by the vaccine, it would not only confirm the close relatedness between PDV and CDV, but it would also provide final proof for this morbillivirus as the primary cause of the recent epizootic in seals. We now report our initial success with two different vaccines.

We used animals belonging to a breeding group of harbour seals kept in isolation for many years. So far no signs of phocid distemper have been observed in this group. For ethical and practical reasons the study was limited to eight adult animals. Six of these were vaccinated twice intramuscularly at two-weekly intervals followed by a third vaccination four weeks later. Two received a candidate subunit iscom CDV vaccine, prepared in collaboration with Coopers Animal Health Ltd (Berkhamsted, UK) as previously described[4]; the other four were vaccinated with a candidate inactivated whole virus CDV vaccine, kindly provided by Duphar BV (Weesp, The Netherlands). The other two animals were sham-vaccinated with an antigen-free preparation.

Before vaccination, CDV-neutralizing serum antibodies were undetectable (titre below 10) in these animals. After the third vaccination all six CDV-vaccinated animals had antibody titres ranging from 300 to 1,000. Ten days later all eight animals were transferred to a closed swimming pool and challenged, intraperitoneally or oculo-nasally, with a suspension of organ material from seals that had died during the outbreak.

Given similarly, this material produced clinical disease and the development of CDV-neutralizing serum antibodies in dogs[5].

The two sham-vaccinated seals showed signs of acute respiratory disease and mucopurulent nasal discharge about two weeks after challenge and died on days 14 and 18. Viral antigen was detected in the spleens and/or lungs of both these animals with an enzyme-linked immunosorbent assay, using a monoclonal antibody which recognizes the F protein of both CDV and PDV[3-5]. No clinical signs were noted in any of the vaccinated animals (I. Visser, to be published). A threefold or higher (average 15-fold) increase in CDV-neutralizing serum antibody titres observed in all vaccinated animals two weeks after challenge suggests that some replication of PDV had taken place. As is often the case in the natural disease, CDV-neutralizing antibodies were not found in serum samples collected after the death of one of the two seals, probably because of the acute nature of the disease. The other had developed a CDV-neutralizing antibody titre of 30.

Although the number of animals studied is small, the data warrant the conclusion that seals can be protected from phocid distemper by vaccination with certain inactivated CDV vaccines. Since the disease was only produced in animals not vaccinated against canine distemper, the last of Koch's postulates has also been fulfilled, reconfirming that infection with CDV or a closely related morbillivirus is the primary cause of the epizootic.

Superconducting single crystals

SIR—Were large single crystals of the high-temperature superconductors of the type $La_{2-x}A_xCuO_4$ available (where A represents Ba or Sr), their physical and structural properties might provide insight into the still unknown mechanism of high-temperature superconductivity. By use of the travelling-solvent floating-zone method[1], we have grown such crystals and determined their superconducting properties, which we report. The anisotropy of their magnetic and electrical properties will be described elsewhere.

Appropriate amounts of La_2O_3, CuO and $SrCO_3$ powders were mixed in ethanol, dried and calcined in air at 1123 K for 12 hours. The calcined powder was formed into a cylindrical shape, 6 mm in diameter by 50 mm in length, and compressed at a hydrostatic pressure of about 100 MPa. This rod was sintered at 1273–1473 K for 12 hours in oxygen gas and was then used as both the feed and the solvent rod. For crystal growth we used a double-ellipsoidal infrared heating furnace (Nichiden Machinery Ltd) heated by two 1.5-kW halogen lamps[1]. Growth conditions involved growth rates of 1.0–3.0 mm per hour, solvent compositions of 55–80 mol% CuO and a growth atmosphere of 0.2 MPa O_2 (to prevent vaporization of copper oxide from the melt zone).

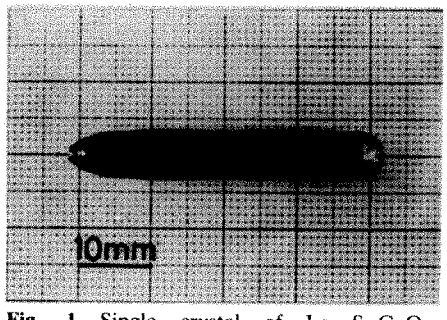

Fig. 1 Single crystal of $La_{2-x}Sr_xCuO_4$. Dimensions are ~ 6 mm diameter and 40 mm length.

A sample of $La_{2-x}Sr_xCuO_4$ in this way, using a solvent of 75 mol% CuO, is shown in Fig. 1. The black, lustreless region at one end comprises a two-phase mixture of La_2O_3 and $La_{2-x}Sr_xCuO_4$, but the remaining portion, black with a metallic lustre, is single-phase $La_{2-x}Sr_xCuO_4$. This region exhibits two facets parallel to the growth direction. Back-reflection Laue X-ray diffraction of these facets gives sharp diffraction spots, confirming the single-crystal nature, and reveals a fourfold rotation axis, identifying the crystallographic plane of the facets as (001). Although the samples contained some cracks, single crystals of about 6 mm in diameter by 15 mm in length could be obtained.

The lattice parameters of the tetragonal

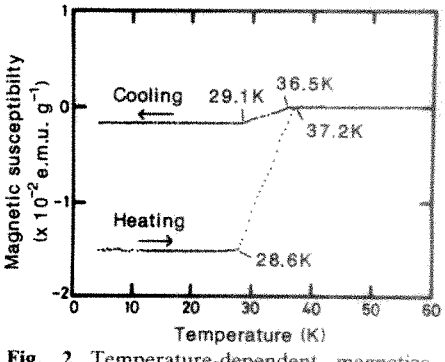

Fig. 2 Temperature-dependent magnetization of $La_{2-x}Sr_xCuO_4$ single crystals. The upper curve is for cooling in a field of 0.936 Oe; the lower curve is for heating in 0.936 Oe after cooling in zero field.

P 36,658

$La_{2-x}Sr_xCuO_4$ crystals, measured by powder X-ray diffraction using Si as a standard, are $a=3.793\pm0.003$ Å and $c=13.20\pm0.02$ Å, which are consistent with values obtained from a sintered $La_{1.88}Sr_{0.12}CuO_4$ feed rod ($a=3.792\pm0.003$ Å, $c=13.21\pm0.02$ Å). Electron probe microanalysis indicates that the Sr content is uniform throughout the crystal, with $x=0.12$; for the feed material, $x=0.15$.

Figure 2 shows the magnetic susceptibility of $La_{1.88}Sr_{0.12}CuO_4$ as a function of temperature, measured using a SQUID magnetometer. The transition temperature observed on cooling the sample in a magnetic field of 0.936 Oe agrees well with that from heating the zero-field-cooled superconducting phase through the transition in the presence of the same field; but the magnetization differs considerably between these two cases. The transition onset temperature and the end temperature are 37 K and 29 K respectively, so that the width of the transition, ΔT_c, is 8 K. This transition is considerably sharper than both that for sintered $La_{2-x}Sr_xCuO_4$ (ref. 2), and that reported previously for a $La_{2-x}Sr_xCuO_4$ single crystal. We found a Meissner effect of 13%.

Isotope dating of the Australian regolith

SIR—The work reported[1] by Bird and Chivas is based on three assumptions: (1) that materials recognized as forming deeply weathered profiles have been formed at some time in the past, on landscapes of low relief under tropical conditions; (2) that the date of such intense periods of weathering can be established by a method of sufficient accuracy to calibrate their oxygen isotope results; and (3) that the clay minerals used for oxygen-isotope analysis were formed during the intense weathering process.

We investigated the first assumption at two sites. The first site was the laterites and deeply weathered profiles on the Hawkesbury Sandstone near Sydney. These materials are generally regarded as erosional remnants of a fossil soil, formed in the Miocene and/or Pliocene, under intense tropical weathering, on a surface of low relief [2,3]. Our mineralogical, geochemical and palaeomagnetic investigations[4-6] demonstrate that these laterites and associated deep-weathered profiles were formed during the gradual stripping of the impervious cover of the Wianamatta shales, which provided the necessary environmental conditions for the mobilization of iron. In other words, all the laterites are the result of a time-transgressive process controlled by the rate at which the Wianamatta shale is being stripped from the Hawkesbury Sandstone, whereas the deep-weathering profiles are explicable in terms of normal bedrock variability.

Our second site was in the Cobar region of central western New South Wales, where silcretes and associated deep-weathered profiles had been recognized[7,8] as having developed on a Tertiary pediplain. Detailed mineralogical and geochemical investigations of these materials[6,9] show that the quartzitic Palaeozoic bedrock of these sites has remained essentially unaltered since a late Palaeozoic deformation and that both silcretes and deep-weathered profiles can be explained in terms of normal bedrock variability.

Thus, even though the materials at these two sites have all the characteristics of deep-weathering profiles and associated laterites and/or silcretes, there is no necessary connection between such characteristics and their formation under some past tropical conditions.

Taking their second assumption, Bird and Chivas themselves[1] doubt the application of stratigraphic and palaeomagnetic methods. Yet they used these methods to calibrate the oxygen-isotope results. They do not comment on how the difficulties were dealt with to make the calibration meaningful. For example, in commenting on the use of stratigraphic methods, Bird and Chivas refer to Exon *et al.*[10] to support the view that previous attemtps to date Australian regolith have often been unsatisfactory. That paper, however, is only the last of a series which throws light not only on dating problems, but also on definitional problems.

The use of palaeomagnetism as a method of dating seems to be similarly flawed, for our investigation of iron in the Hawkesbury Sandstone[5,6] suggests that no past intensive period of iron deposition coinciding with a period of deep weathering can be identified. What is indicated is that iron mobilization and deposition has occurred at a fairly uniform rate over the whole basin since the late Tertiary at least, and this is more than sufficient to explain any of the present-day iron accumulations. Our work casts doubt on studies that have established intense periods of iron deposition at some time in the Tertiary, and in particular on the determinations used by Bird and Chivas to establish the age of periods of deep weathering.

Finally, the long-term stability of the oxygen-isotope composition of kaolinites is fundamental to their use by Bird and Chivas in identifying the time of formation of clay minerals. If this is so, it can equally be used to support the contention that in any weathering mass there is inevitably a contribution from inherited clay minerals, which, as we have shown for the materials derived from the Triassic Hawkesbury Sandstone and the Palaeozoic rocks of Cobar, can be the dominant factor. Even though the degree of inheritance is less in profiles developed on igneous rocks, inherited material will always be present. Bird and Chivas do not appear to have considered this factor.

These doubts about the application of the methodology to the dating of deeply weathered regolith lead us to question the significance of the three ages of weathering identified by Bird and Chivas. Such weaknesses must be resolved before any further progress can be made in the study of deeply weathered Australian regolith.

T.R. PATON
P.B. MITCHELL
P.A. HUNT

School of Earth Sciences,
Macquarie University,
North Ryde, Sydney,
New South Wales 2109, Australia.

BIRD AND CHIVAS REPLY—We fully agree with Paton *et al.* that the Australian regolith is a spacially and temporally complex entity, and that weathering remains a major surficial process on the Australian continent. Many of the points raised are valid, indeed obvious; but stringent space requirements precluded full discussion[1]. We discuss these points in detail in a forthcoming paper[11], so here we will only correct some of the misconceptions held by Paton *et al.*

Their statement of the suppositions on which the study was based is erroneous. The supposition we make is that the isotope composition of meteoric waters in Australia has been changing with time.

We do not state that lateritization/deep-weathering requires tropical conditions and low-relief landscapes (although such conditions may aid the process); in fact, a major conclusion of this and our other studies[12] is that tropical conditions are not required. We do state that such weathering requires humid conditions and unimpeded drainage, and that as a result, infiltrating waters are not likely to have been subject to evaporative modification of their isotope composition.

We do not believe that such profiles can be independently dated with great accuracy (except in exceptional circumstances, such as dated weathered basalt overlain by basalt) which is why we have delineated only three age groups, spanning probably 200 million years.

We are aware that weathering can be an episodic or continual process, that weathering 'events' can be superimposed in a single profile, and that clay minerals can be inherited from the parent rock (although large quantities of kaolinite are

not common in most metamorphic or igneous rocks). But the increase in the isotope composition of meteoric waters with time means that low $\delta^{18}O$ clays (grossly out of equilibrium with modern waters) must have formed in ancient and cooler weathering regimes.

The division between fields B and C does not require the rejection of the independent age constraints, because in most cases the only independent constraint is simply that the weathering is older than mid-Tertiary. The division among pre-mid Tertiary samples is made on isotope grounds because the low $\delta^{18}O$ clays could not have formed during the comparatively warm climate of the late Mesozoic and early Tertiary in Australia. The isotope composition of the few samples of demonstrably pre-late Mesozoic age (such as kaolinite from regolith profiles beneath the Jurassic Wisanger Basalt, +10.2‰ and Jurassic Algebuckina Sandstone, +12.3‰) confirms the subdivision.

We are aware of the complexities involved in the palaeomagnetic dating of iron accumulations and, as indicated in our paper, we do not believe that there is necessarily a genetic or temporal link between the formation of a clay assemblage and an iron-rich zone in a regolith profile. We did not rely heavily on palaeomagnetically dated profiles for the reasons stated by Paton *et al.*, but in cases such as the Morney profile in south-west Queensland[13], the palaeomagnetic date can be taken as a minimum age for the development of the clay mineral assemblage.

With reference to the work of Paton *et al.* on the Cobar region, note that a kaolinitic sample collected from a roadcut 23 km south of Enngonia (which did not have any independent age control) yielded a $\delta^{18}O$ value of + 18.1‰ (post mid-Tertiary), consistent with the conclusions of those authors.

Finally, Paton *et al.* comment on the paucity of data points, particularly in the post-late Tertiary group, having previously described in detail the difficulties inherent in finding suitably unequivocal localities to sample. The post-late Tertiary samples we analysed were largely obtained from regolith developed on the late Tertiary–Quaternary volcanic provinces of Victoria and north Queensland. If Paton *et al.* wish to point out other such unequivocal localities, we would be glad to sample them.

Origin of life

SIR—Miller and Bada[1] have made a valuable contribution to the understanding of the organic chemistry of high-temperature hydrothermal systems. They are, however, incorrect in citing my work[2] as supporting the hypothesis that life began in vents at mid-ocean ridges[3]. This important hypothesis has stimulated much debate[4] and is extremely interesting, but the evidence is strong[2,5,6], as Miller and Bada[1] have confirmed, that conditions are probably too extreme in submarine ridge vents.

The much more likely candidate for our birthplace is in subaerial (that is, land) hydrothermal systems. In them, temperatures at high level are commonly around 40 °C, with *p*H fluctuating, often even mildly alkaline. Closely juxtaposed parts of a system may vary greatly in temperature, and both water-dominated and relatively dry gas-dominated conditions are possible, often in rapid succession in the same place. There may be rapid influx of fluid of very different chemistry, from considerable depth. Many potential mineral catalysts occur. It is for these reasons that I concluded[2,5,6] that the likely setting of an RNA world would be in a subaerial, meteoric water hydrothermal system. Perhaps nowhere else in the Archaean world were conditions so favourable for that extraordinary event, the origin of life.

E. G. NISBET
Department of Geological Sciences, University of Saskatchewan, Saskatoon S7W 0W0, Canada

1. Miller, S.L. & Bada, J.L. *Nature* **334**, 609–611 (1988).
2. Nisbet, E.G. *The Young Earth* (Allen and Unwin, Winchester, Massachusetts, 1987).
3. Corliss, J.B., Baross, J.A. & Hoffman, S.E. *Oceanologica Acta* **4**, Suppl. 59–69 (1981).
4. Joyce, G. *Nature* **334**, 564 (1988).
5. Nisbet, E.G. *Nature* **321**, 206 (1986).
6. Nisbet, E.G. *Episodes* **9**, 83–90 (1986).

MILLER AND BADA REPLY — Nisbet proposes that the origin of life took place in 40°C vent waters rather than 350°C vents. Russell *et al.*[2] have also claimed that lukewarm vent waters were the site of important prebiotic reactions. The vent waters that are referred to are apparently hydrothermal waters cooled by mixing with sea water or by loss of heat to rocks. Because the high-temperature conditions would decompose all the organic compounds, the vent waters mixed with sea water would have less organic material than the ocean as a whole.

It is not clear what is to be gained from this process over heating parts of the primitive ocean to 40°C on a beach or in a lagoon. An alternative is to heat the primitive sea water to 40°C, but not much higher, by circulating it through heated rocks. This apparently does not occur near submarine vents, but may take place near volcanoes (H. Craig, personal communication). Again there seems little to be gained by invoking this type of process. The chemical reactions taking place at 40°C are more rapid but still similar to those at 0°C, with a few exceptions (for example, template polymerizations may not work at 40°C because of the melting of the helix). Taking the heat of activation of a reaction as 20 kcal mol^{-1} and assuming that 1 part in 10^5 of the ocean is at 40°C, then 99.9% of the reaction would occur at 0°C and only 0.1% at 40°C.

Russell *et al.* refer to the reported detection of glycine in Red Sea hydrothermal brines[2] as evidence that a biotic synthesis occurs in mild hydrothermal vents. This glycine is a contaminant, however, which bleeds from the Chelex resin[3-5] employed in the analytical scheme. In addition, no other amino acids were reported[2], which would be usual for a prebiotic synthesis.

If lukewarm vent water, and not the ocean as a whole, came in contact with minerals that catalysed critical prebiotic reactions, as proposed by both Nisbet and Russell *et al.*, our argument could change. It is not feasible to evaluate this possibility until the minerals and reactions are named. It is to be noted that an important role in prebiotic chemistry for minerals and clays has so far not been demonstrated. As for the role of hydrophobic surfaces a primitive oil slick[5] may have been more important than the mineral surfaces suggested by Russell *et al.*

Barnacle taxonomy

SIR—Crisp and Fogg[1] attack what they consider "mere changes of opinion" in establishing and changing names of taxa above the species level. To alleviate attendant inconveniences, at least among the barnacles, they offer a remedy of

compromise between the classification of Linnaeus, in which all species were lumped under *Lepas*, and a current system[2,3]; namely, return to Darwin's classification of 1851–54 (ref. 4) and limit formal appellation of subsequently recognized species–group taxa to the subgeneric level.

It is possible, for some taxonomic reason or another, that a current genus might be more appropriately recognized as a subgenus. But it does not take a monkey wrench thrown into the gears of an entire system, as Crisp and Fogg have proposed, to enact such changes; when fine tuning is necessary, it can be made on an individual basis. No precedent would be set for, after all, "the despised" subgeneric category is still in use among the barnacles. Therefore I would like to offer the following rejoinder.

Darwin's attempts to estimate relationships between taxa, and concomitantly their patterns of diversity, were clearly hindered by taxonomic inadequacies and perceptions prevailing at the time. Many biological species were lumped as single species and, concomitantly, many now well recognized genera were lumped as single genera. Of *Balanus concavus* he wrote[4], ". . .a good instance of the amount of variation which seems especially to occur in most of the species which have very extensive ranges." But this and the half dozen other 'variable' species he recognized have all turned out to represent several to numerous species[5–7]. Thus, with their diversity and relationships poorly understood, it is no wonder Darwin found barnacle biogeography of "no particular interest, for the species are not sufficiently numerous; and, what is still more adverse, the genera, with unimportant exceptions, range all over the world; so that there is no scale of difference, and it cannot be said that these two regions differ in their species".

Thus knowledge of much of the diversity and our perception of the biogeography of barnacles languished for the more than a century after Darwin, despite the results of numerous expeditions and collections from deep as well as shallow water, and the advances in our understanding of the species concept and ecology. It took major systematic revisions to reach the point where barnacles became biogeographically interesting, and then to where they began not only to corroborate but to elucidate general principles in marine biogeography[8–11].

What Crisp and Fogg fail to appreciate is that taxonomic recognition of the relationships between species and species groups, at and above the generic level, is necessary if evolutionary pathways and patterns are to be recognized. Continuing adjustments to such a system, usually enacted when knowledge has increased to the point where relationships are no longer being accurately portrayed, are inevitable inconveniences. If someone eventually comes up with a better method of handling such a database, fine, but in the meantime the remedy of compromise proposed by Crisp and Fogg[1] does not satisfy these prerequisites.

Antigen presentation by B cells

SIR—The recent letter of Lassila *et al.*[1] clearly demonstrates that B cells cannot be the antigen-presenting cells that lead to priming of helper T cells. This contrasts with data from several laboratories[2–4] demonstrating that B cells are required for the priming of $CD4^+$, class II MHC-restricted T cells that proliferate in response to antigen as discussed by De Franco[5]. We would like to offer the following explanation for these apparently conflicting results.

CD4 T cells belong to two separate subsets that differ in their functions[6–9] and in their requirements for priming[2–4,8–10] and accessory factors[11]. One subset of CD4 T cells (helper T cells, or Th2) is effective in helping B cells make antibody, while the reciprocal subset of CD4 T cells (inflammatory T cells, Th1) is active in T-cell proliferation assays, cytolysis, macrophage activation, delayed type hypersensitivity and in fact will suppress B-cell responses[12,13].

Studies in B-cell-deficient mice indicate that B cells are required for the priming of the subset of CD4 T cells that proliferate in response to antigen[2–4], but are not required for the priming of the subset of CD4 T cells that help B cells secrete antibody[8–10]. The data also demonstrate that the B cell required for priming the proliferating CD4 T cell must be antigen-specific and MHC matched to the CD4 T cell[4].

By contrast, the clonal expansion of the Th2 subset requires IL-1[10,11], a molecule expressed abundantly on macrophage membranes but not on B cells or dendritic cells. Thus, the macrophage is almost certain to be the cell that presents antigen: self MHC complexes required for the priming of this CD4 T cell subset[8,9].

Given these facts, it is not surprising that in the experiment of Lassila *et al.* the subset of CD4 T cells that helps B cells could not be primed in the absence of syngeneic macrophages. However, this observation cannot be taken to mean that no priming of CD4 T cells has occurred. Had they measured priming of the CD4 T cell subset that participates in *in vitro* proliferative responses, one would expect such priming to have occurred. Likewise, the seemingly paradoxical observation that transgenic mice fail to make antibody responses if they have B-cell but not macrophage class II MHC expression[14] is probably due to the requirement for macrophages in helper T-cell priming. Finally, if Th1 tend to be suppressive of antibody production, the problem of avoiding the priming of helper T cells by B cell idiotypes, on which the Lasilla *et al.* letter is based, may be moot.

The paper of Lassila *et al.* is an elegant demonstration of the fact that B cells are ineffective at priming those CD4 T cells that can help B cells. It will, however, require further study to determine whether this inability of B cells to prime CD4 helper T cells applies to all CD4 T cell subsets. Unlike the virgin CD4 T cells of Lassila *et al.*, we are certainly turned on by the idea that macrophages are required only to activate the subset of CD4 T cells that is most effective at helping B cells make antibody, while B cells almost certainly can prime those CD4 T cells that mediate inflammatory responses such as cytotoxicity, macrophage activation, or delayed-type hypersensitivity, as well as suppression of antibody responses[9,12,13].

Improving on Darwin

Niles Eldredge

Evolutionary Processes and Metaphors. Edited by Mae-Wan Ho and Sidney W. Fox. *Wiley:1988. Pp.333. £35.95, $85.*

EVOLUTIONARY theory continues to be characterized by sharp dissent and often acrimonious debate. The 'synthesis' — that relatively tranquil period that began roughly in 1930 and ended in the mid-1960s — in retrospect seems anomalous. Since its birth in the 1850s, the subject has for the most part been a battleground; controversy is nothing new, but rather the normal state of affairs.

Many modern evolutionary biologists, myself among them, have proclaimed the dissension to be healthy. After all, the very essence of the scientific process entails questioning the received wisdom of the past. Yet at times the dialogue seems to transcend the simple search for a deeper, more accurate description of nature. Sometimes the theme is less one of correction and building upon a body of accumulated knowledge and more a clarion call to throw out the old — often with little clear development of what might take its place. The multi-authored contents of Ho and Fox's *Evolutionary Processes and Metaphors* tread a precarious path along the border between the bright search for a better understanding of evolution, and the darker quest to expunge modern biology of what are perceived as the evils built into Darwin's original ideas. The book's lowest moments come when darwinian thought is presented as at best an outmoded metaphor (shades of Jeremy Rifkin's *Algeny*) and at worst the personification of evil, as when competition rather than cooperation is seen to be central to a description of biological nature. This, and the repeated calls for a 'new paradigm', are the least prepossessing features of the book. How often one wishes that scientists would not take Thomas Kuhn so literally: no one wants to be guilty of doing mere 'normal science', so the search for new paradigms to overthrow the old becomes the norm.

But, for all its flaws, *Evolutionary Processes and Metaphors* is not just another exercise in Darwin-bashing — although those in whom the response is reflexive to defend reigning orthodoxy will have little difficulty finding enough absurdities and false characterizations of darwinian evolutionary biology to dismiss the book outright. If David Hull is right[1], and science (and indeed the entire world of ideas) proceeds in a fashion that basically mimics natural selection, more can be accomplished by dwelling on what seems to be promising in the book under review than complaining about the more flagrant red herrings it contains.

There are two basic sources of progress in scientific discourse: new data pertaining to phenomena previously unexplored; and conceptual clarification of phenomena previously considered, in some instances prompted by new data that reopen old issues. For example, several authors broach the topic of 'self-organization' in various biological systems, reflecting a resurgence of interest in this theme in evolutionary biology. And a number of the 15 essays touch on the recently re-opened issue of Weismann's 'barrier'. Received wisdom, stemming from Weismann, held the distinction between germ line and soma to be inviolate, thereby ignoring the otherwise well-established facts that germ line is generated afresh from somatic tissue in plants, and is hardly 'sequestered' to the extent conventionally supposed in many animal phyla[2]. The weismannian distinction of soma and germ line, with its asymmetric causal emphasis that the germ line determines the soma, but that what happens to the soma cannot affect the germ line, became the central dogma of molecular biology.

That somatic change can indeed become heritable naturally affects views on how the evolutionary process works. Thus I was particularly struck by Cullis's essay reviewing heritability of somatic mutations in flax, which poses the very real possibility that "higher plants have a genetically controlled variation generating system". Cullis takes pains not to claim that such induced variation arises as a response to organismic needs (a core neodarwinian postulate is that variation is generated without regard to organismic needs, that is, it is random with respect to selection). Yet in the very next essay, which is otherwise a balanced and useful account of the evolutionary implications of "new genetic mechanisms", Pollard asserts that the flax evidence indicates that germ-line DNA can develop "genetic variation *in response to the modified condition*" (emphasis mine) — thus, in nuance at least, going rather farther than Cullis in posing a more severe if apparently unsubstantiated challenge to orthodoxy.

Natural selection, perhaps unsurprisingly, provides much of the book's thematic continuity, as much in the guise of 'metaphor' as 'evolutionary process'. Several authors question the propriety of the very term 'selection', as (they claim) nothing in nature is actually doing the selecting. It is, according to Ho (as but one example), as if natural selection had merely been substituted for Paley's Divine Watchmaker: Darwin fashioned natural selection as a mechanistic, naturalistic substitution for a concept of a supernatural Creator in order to explain organismic design in nature. While this is so, complaining that selection is an inappropriate term because there is no selector ignores the parallel with *artificial* selection that Darwin had in mind. It was simply a terminological parallel that led to the choice of word. The critique does not speak to the real issue: is there anything to the notion of natural selection as evolutionary process?

Some of the essays in the book, notably those by Ho, come close to concluding 'no'; because natural selection is an outmoded metaphor, it seems we are to conclude that it is not a process that occurs in nature, at least to any extent that would be helpful in understanding evolutionary history. In trying to emphasize the positive contributions of this book, though, let us consider a related theme — 'holism' — that seems to hold more promise. Some contributors complain that traditional selection theory treats organisms in a passive manner: organisms are commonly portrayed as being at the mercy of their environment. More strongly, a number of them feel that the organism has (in theory) been inappropriately divorced from the environment when actually organisms and environment form a holistic unity. Thus development, and phylogenetic changes in developmental patterns, can be seen as arising from interaction between organism and environment in a dynamic fashion that is not fully taken into account in conventional views of the relation between environment, adult phenotype and development — views in which natural selection plays, of course, an important role.

This line, when developed well (as in Oyama's essay) is thought provoking. Yet too often the conceptual lumping together of ontologically separate entities leads to confusion rather than clarity. The best example may be natural selection itself. Darwin saw that organisms are both economic and reproductive 'machines' (itself a loaded metaphor; in their introductory essay, Ho and Fox proclaim emancipation from just this sort of 'mechanical' world view). How well organisms within a local population fare economically, in a world of finite resources where not all offspring can survive to reproduce, is bound to affect their relative reproductive success. Yet the term 'fitness', defined holistically simply as probability of reproductive success, overlooks

Reader Service No.2

and obscures the various elements that may contribute to differential reproductive success. It is useful, in other words, to distinguish economic from reproductive activities within single organisms, the better to understand what causes affect reproductive success. Similarly, eliding the distinction between organism and (physical and biotic) environment threatens to obscure causal pathways, whether they be the role of environment in 'selection', or the effect organisms have on their 'environments'. No one denies that organisms and environments are intimately linked — no more than anyone denies that organisms are individuals, despite the usefulness of distinguishing their economic and reproductive functions when it comes to understanding the nature of natural selection.

Many essays in the book appear to be summaries of past work, in particular those devoted to the implications of phenomena newly apprehended. Especially at the molecular level, knowledge of such phenomena can only enrich our understanding of evolutionary process. The assumption that molecular mechanisms that bias genetic transmission somehow call into question the validity of other biasing mechanisms posed in the past — natural selection, say — is fortunately only vaguely hinted at in some contributions. The essays I found most appealing (those by Hailman and Gray on methodological issues in teasing apart process from results in evolutionary studies; by Gordon and by Bateson on evolutionary aspects of behaviour; by Cullis on variation; and by Oyama on development) propose links to the darwinian paradigm on which they quite naturally wish to improve. Theirs seems the better grasp of the past; and they write with the implicit realization that, rhetoric aside, improvement in the conceptual basis of any science usually involves keeping what's right, fixing what's not and adding the apparent implications of newly gained knowledge. □

Highs and hopes

Roger Guillemin

Messengers of Paradise: Opiates and the Brain. By Charles F. Levinthal. *Anchor Press/Doubleday, New York:1988. Pp. 229. $16.95.*

COMING after Abrams's *The Milk of Paradise* (1962) and Wright's *Dark Paradise* (1982), we now have Levinthal's *Messengers of Paradise*. Levinthal's purpose in this non-technical little book is to recount the story of the discovery in 1975 and 1976 of the enkephalins and endorphins, molecules found in the human brain (and in fact that of all vertebrates) which have the biological activities of opiates, and having done so to tell us how our own endorphins are responsible for the bits of paradise that occasionally come our way throughout life.

Levinthal, a professor of psychology at Hofstra University on Long Island, New York, first provides a short and entertaining history of the use of opium from antiquity to these days of massive illicit use. But why should the human brain have highly specialized receptors for the opiate molecules in the sap of the poppy? Because — so went the hypothesis — opium molecules possibly resemble some substances that are made normally by the brain and are involved in its dealing with those very same phenomena — pain and mood — that are modified by opiates. The next step was to prove it.

In yet another among many attemps to emulate Jim Watson's *The Double Helix*, Levinthal goes on to tell the story of the search for these endogenous ligands of the opiate receptors, and their final characterization. But the difference between Watson's book, and all the others that have purported to describe the high adventure and competition involved in the making of scientific discoveries, is that Watson was centrally involved in the work that led to the proposal of a structure for DNA. He knew what he was talking about. His imitators have generally had only second- or even third-hand knowledge of what they have described, and the resulting books, although plausible to the lay public, have been deeply flawed.

Such is the problem with this part of *Messengers of Paradise*. I do not remember Levinthal's name in the literature dealing with the opioid peptides in the days when I was active in that field. Thus, the chapters that are meant to describe the intellectual process involved in the research, as well as the accompanying human drama, are unsatisfactory. Here readers may be easily entertained, but they will not become well-informed. This is not a work of scholarship. An accurate and complete historical study requires considerable time and devotion, and above all a scholarly sense of purpose in the endeavour (for a superb and rare example, see H. F. Judson's *The Eighth Day of Creation*, 1979).

So much for the messengers. What about paradise? Simple: paradise is a form of bliss, or vice versa, that is entered or glimpsed thanks to endorphins *à toutes les sauces*. Struggles over pain, social comfort, alienation and addiction, the quest for coherence and certainty, ecstasy, and finally creativity and laughter, are the subjects of a series of vignettes in which

everything is explained or proposed to be explained by too much, too little or just the right amounts of opioid peptides in our triune brains. After all, Somerset Maugham, in an exquisite essay on Zurbaran as a mystic painter (published in *The Vagrant Mood*, 1952), said plainly that mystical ecstasy, "generally the result of prayer and mortification", "may also arise through the influence of a drug, opium, for instance".

I have a lot of sympathy for some of the ideas and proposals described by Levinthal, and nothing would please me more than to be convinced that they are substantiated or even substantiable. There is little doubt that the opioid peptides are involved, somehow, in our homoeostatic handling of a variety of painful events. But even here I say *somehow*, as there are still many unanswered questions. For instance, I do not know of a definitive demonstration that acupuncture 'works' exclusively through the endorphin system. The 'proof' in such statements is usually that the expected effects are allegedly prevented by prior administration of naloxone, a powerful opiate antagonist. In the hands of critical investigators, such studies are difficult to perform and even more difficult to control. Moreover, we now know of effects of opioid peptides which are not naloxone-reversible.

A characteristic of many of these facile interpretations is the persistent confusion between the significance of blood levels of endorphins (which represent levels of endorphins of pituitary origin) and what happens or may happen in brain levels of endorphins, in one system of neurons or another. We have, so far, practically no way of knowing what is going on in such systems, even in laboratory experiments let alone the clinic. Intravenous injection of massive amounts of β-endorphin into animals or man has no effect whatsoever on measured functions of the central nervous system, because peptide molecules of this type do not penetrate the blood–brain barrier. Thus, relating the long distance runners' 'highs' to their blood levels of endorphins is meaningless.

Yes, the discovery of the chemical structure of the endogenous opioids found in our brains was a remarkable achievement. But it is still too early to know what to make of it, as basic knowledge or in daily life. Most of the original questions about the role(s) in health or disease of the enkephalins, the endorphins, and the other opioid peptides that were recognized later, still remain wide open. For all I know, some of Levinthal's enthusiasm — and, let's face it, that of most of us originally involved in these discoveries — may still be vindicated. □

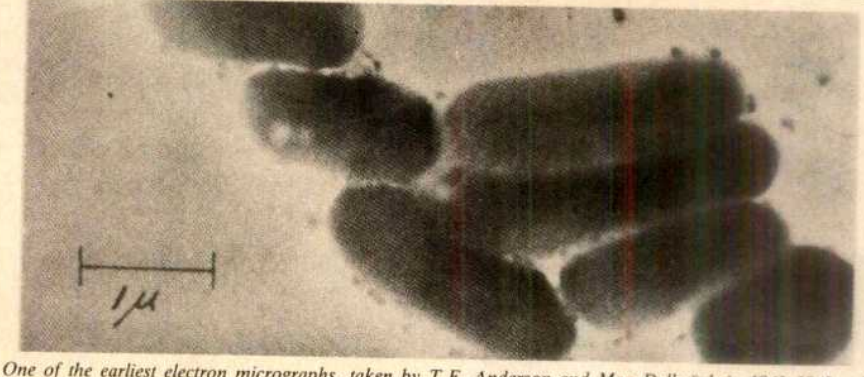
A growing sphere of knowledge

Ghillean T. Prance

Biodiversity. Edited by E. O. Wilson. *National Academy Press: 1988. Pp.521. Pbk $19.50. Distributed in Europe by Wiley, £16.80. To be published in hardback next month, £27.85, $32.50.*

UNTIL recently, 'biodiversity' — short for biological diversity — was a term used only by a few biologists. Today it is the subject of bills in the US Congress and of US Aid funding, and it was the central concern of a special meeting of the Pontifical Academy. Biodiversity has become the dominating theme of many scientific conferences, as it was at the August 1988 meeting of the American Institute of Biological Sciences held in Davis, California.

There is good reason for this rapid upturn of interest in the topic. In the past two years, alarming details have emerged of the rates of destruction of the tropical rainforest that harbours some 50 per cent of the world's biological diversity. Satellite photographs have shown that, in 1987, 204,000 km^2 of forest were burned in Brazil, and for 1988 the estimate is near to 250,000 km^2, much of the loss being of primary rainforest. A few years ago, environmentalists were called to task for suggesting that the annual worldwide total of rainforest destruction was 50 km^2. But the proven rate of destruction, the patent effect on climate and the number of species that are in danger of extinction have now combined to make biodiversity the centre of scientific and political attention.



Biodiversity, the book under review, is based on a national forum which took place in September 1986 at the Smithsonian Institution, under the auspices of the US National Research Council. Made up of 57 chapters written by specialists, it is a thorough review of the many aspects of the subject. Although the emphasis is on tropical rainforest, the threats to many other ecosystems, such as grasslands, oceanic islands, coastal zones and oceans are covered. Two of the main facets of biodiversity are stressed — species diversity, and habitat and ecological diversity. Genetic diversity is not considered in any detail.

There is a particularly useful section of five chapters on the value of biodiversity, and another on the contribution science and technology can make. Here, the role of botanical gardens and zoos is given prominence. Other topics covered include agroforestry and other sustainable systems of management, political aspects of protecting diversity and ethical issues. The contents of the final section, "Ways of Seeing the Biosphere", vary from a native American account from New Mexico giving the viewpoint of a Pueblo Indian, to a description of the Earth as a living organism by James Lovelock, the creator of the Gaia hypothesis.

Each contribution is brief and to the point, the most of them have references to further work on the particular subject dealt with. The book does not contain many new ideas or concepts; rather, its value lies in bringing together an appropriate diversity of human talent to address a topic that is vital for the survival of life on Earth. It is written in such a way as to be understood by the general reader and, with its broad scientific content, will be used for teaching courses.

In the two years since the national forum was held, immense amounts of further evidence of the threat to biodiversity have been gathered. Yet with its comprehensive treatment the appearance of this book remains timely. It deserves wide notice. □

A walk on the wilder side

A. Rupert Hall

Let Newton Be! A New Perspective on His Life and Works. Edited by John Fauvel, Raymond Flood, Michael Shortland and Robin Wilson. *Oxford University Press: 1988. Pp.269. £17.50.*

Isaac Newton, an eccentric professor of mathematics at Cambridge unaccountably chosen for the chief office of the Royal Mint in 1696, was author of two books, published posthumously, *The Chronology of Ancient Kingdoms Amended* and the *Prophecies of Daniel and John*. Further, he left behind a vast quantity of manuscripts dealing with his business at the Mint, his views on the doctrine of the early Church, and alchemy. As scholar, theologian and monetary expert Newton was neither original nor up to date, and in these fields his work has been passed by without ever receiving much consideration.

If this had been Newton's obituary, it is doubtful that he would be of more interest today than Archbishop Ussher, even to scholars. But in fact Newton also wrote the *Principia*, *Opticks* and *Optical Lectures*, a large number of papers in *Philosophical Transactions* and several mathematical texts. It is a truism to affirm that if he has any place in the history of civilization, it is because of his scientific writings.

This elegantly produced collection of papers — with an appalling dust jacket — tells us more about the eccentric don than about the experimenter and mathematician known to scientists. It is all, or nearly all, quite true: Newton (like other mathematicians) did look into 'equal temperament' in music and he did have (to us) bizarre ideas about the reappearance of the harmonic ratios in other parts of physics, such as the optical spectrum (as Penelope Gouk relates). He did (as P.M. Rattansi and she report) draft learned pages on the Pythagoreans' ancient knowledge of the deeper principles of physics, such as the inverse-square law of gravitation. He did meticulously ascertain the life-span of the locust (species unstated) in order to calculate the prophesied length of the expansion of Islam. And he did (as J. Henry and J. Golinski explain) painstakingly copy out the (apparent?) gibberish of the alchemists, with their fanciful symbolic pictures, and himself experiment on the volatility of metallic salts and the reality of Diana's Doves.

As Keynes wrote long ago, Newton's mind was complex and strange. He accepted as unquestionable the priority of Hebrew learning. He was equally confident that ancient texts were pregnant with metaphors and codes, whose meaning could not appear to the unlearned. Only by discovering it, and so disclosing and restoring the pure wisdom of the infant world, could men perform their duty to God by understanding his Creation and Providence and so prepare for his Son's second advent. As P.M. Rattansi says, natural knowledge was but one element in Newton's *weltbild*, of whose theological character a strong hint is conveyed in the final scholium of the second *Principia* (1713).

Since Keynes (and so many others afterwards — nothing here is really new) read the pages that Newton would have kept hid, our knowledge of him has become richer but more confusing. Scholars are in danger of writing about the Newton who was insignificant to the neglect of the Newton who transformed thought. To be dismissive of Newton — as Whiteside, Westfall and Cohen, for example, have *not* been — is absurd. We see in this book two pictures of Harpo Marx representing Isaac Newton in the 1957 film *The Story of Mankind*, and many images taken from the books of the mystic 'platonist', Robert Fludd; it is doubtful if any of these is relevant to either Newton, the open or the concealed. Nor was Newton himself muddled about the natures of the diverse studies he pursued with equal ardour.

We need to be cautious about the inference that the scientific Newton drew inspiration and principles from the esoteric reading of his other self. My impression is that when experimenting or measuring or developing a structure of geometrical theorems, Newton was as much a 'scientist' as if he had had no other interests. In this book the investigations of the scientific Newton are well described, though necessarily in elementary language, by John Roche (*Principia*), C. Hakfoort (optics) and Jon Pepper (mathematics) — no place here for the kind of technical article ("Newton and the Calculus of Variations") that seemed appropriate 60 years ago. □

Pollen stations

John Birks

Paleopalynology. By Alfred Traverse. *Unwin Hyman: 1988. Pp.600. Hbk £50, $75; pbk £24.95, $34.95.*

Palaeopalynology is the study of fossil pollen grains, spores and other organic microfossils (excluding diatoms and nannofossils) preserved in rocks and sediments. Among the objects of interest are acritarchs, dinoflagellates, microforaminiferal inner tests, chitinozoans, scolecodonts, selected algae, fungal, bryophyte and pteridophyte spores, and, of course, pollen from the recent past to the Precambrian. With such an enormous taxonomic diversity and stratigraphical range, it is inevitable that palaeopalynologists tend to be divided according to their specific stratigraphical or taxonomic interests, or both. And it is not surprising that, until now, nobody has written a book in English that sweeps across the subject as a whole.

Alfred Traverse, of Pennsylvania State University, has done just that. His book covers what palaeopalynology is and why it works; the basic biology and chemistry of palynomorphs; the stratigraphical palynology of the Precambrian and all the way through to the Quaternary; the production, dispersal and deposition of modern pollen; and applied palaeopalynology and laboratory techniques. It is profusely illustrated and has an extensive and up-to-date bibliography. Despite the enormous amount of information included, it is easy to read, with fascinating comments about many of the pioneers of the subject.

The book's greatest strength lies in the wealth of practical information it contains — the appendix on laboratory procedures is a monograph in itself and provides palynologists with an invaluable illustrated account of preparation techniques. The chapter on pollen morphology abounds in common sense and sound judgement, and includes a helpful synthesis of the different morphological terminologies and philosophies that are involved in understanding pollen-wall structure, along with an excellent account of the neglected topic of pollen orientation. The 30-page glossary is important for everyone concerned about precise terminology.

Traverse has maintained an admirable balance between the chapters on stratigraphical palynology and has avoided the temptation to put undue emphasis on the Tertiary (his main speciality). The book's weaknesses are the inevitable result of its breadth — some topics seem to my Quaternary palynological eyes to be covered too superficially. For example, there is virtually no mention of pollen-analytical studies of the effect of prehistoric man on vegetation, one of palynology's great success stories in Europe; and little is made of palynology's contribution to climatic reconstructions in the Quaternary or to modern plant ecology.

Traverse's book contains much of interest to all palaeopalynologists and it will, I hope, help to narrow the gaps between the different sub-disciplines. I urge all pollen analysts, novice or expert, to acquire and read it, and to share the author's manifest enthusiasm for his subject. □

Eighteen eighty nine and all that

W. F. Bynum and J. L. Heilbron

An anniversarial cornucopia featuring rubber gloves, Louis Ilosvay de Nagy-Ilosva, the Eiffel Tower, nuclear fission, the Swedish Academy of Sciences, J. Willard Gibbs, the omega minus meson, Antoine Laurent Lavoisier, Timothy the tortoise and much, much more.

In continuance of the public service begun here last January, we again fill the slate of impending anniversaries according to the decimal system. In this we have subordinated our own preference, which runs to base 60, to the wishes of our many correspondents. The century remains our unit; boldface numbers in parentheses indicate multiples of a hundred years. The progress of science cannot be arrested for long, however. We observe, as a hint for the future, that 'hundred' has signified 106 in counting sheep, 120 in counting balks, boards and bomspars, 124 in counting cod or haberdine, and 225 in counting onions and garlic.

In the mundane reckoning, the French Revolution (**2.0**) may occupy pride of place. The storming of the Bastille on 14 July 1789 was greeted variously throughout Europe and the New World, but time has softened the passions and mellowed the emotions. We can hope that *liberté, égalité, fraternité* will be practised as well as celebrated in 1989. Science and technology, too, can claim their revolutions, both intellectual and social. Among the biggest of conceptual revolutions was that in chemistry, which flowered in the city of the Bastille in the year of its storming; Lavoisier, the prime mover in the one revolution, became a victim of the other. Among the social–technological revolutions on which we can reflect in 1989 are those founded on photography, nuclear fission, the jet engine and miracle drugs.

Towering achievement — a contemporary Punch *caricature of Alexandre Gustave Eiffel (Mary Evans Picture Library).*

1889 (1.0 centenary)

This year, in Spring, admirers of gigantism have to celebrate the hundredth anniversary of the completion of the Eiffel Tower. Built for the international exposition of 1889, the tower at 985 feet rose twice as tall as the tallest structure then in existence; it stood and stands for the height of wrought-iron technology. It has also been an instrument of scientific experimentation. In 1909 (**0.8**) Thomas Wulf designed a quartz-fibre electroscope especially suited to detect the presence of ionizing radiations. The following year he carried it to the top of the Eiffel Tower and found that its rate of discharge did not decline with height as expected. Confirmation and extension of this result during balloon flights by Victor Hess and others led to the discovery of cosmic rays. The underlying assumption of the measurement, that the leak of an insulated body exposed to the air does not in general arise from failure of the insulation, had been demonstrated definitively 20 years before (**1.0**) by C. V. Boys.

Shortly after the Eiffel Tower peaked out at 300 metres, Ludwig Mond — born 1839 (**1.5**), died 1909 (**0.8**) — found a cheap way to make replicas of it in nickel. This was the discovery of nickel carbonyl, which gave wings to the heavy metals (as Kelvin put it) and also much profit to Mond enterprises, because it led to a cheap way to extract nickel from poor ores. The profit in turn gave wings to British scientific and cultural life through Mond's benefactions, which included gifts to the National Gallery, the Royal Institution and the Royal Society.

Further towards higher things, 1889 was a fine year for students of the stars. Edward Charles Pickering (died 1919 — **0.7**), a passionate photographer of the heavens above Harvard, discovered the first known spectroscopic binary — a double star not resolvable by the telescope, but detectable by the periodic doubling of its spectral lines. Astronomers then residing on Mercury and facing the Sun would not have discovered this interesting phenomenon, nor, indeed, would they ever see any star but ours; for, as Giovanni Virginio Schiapparelli observed 100 years ago, Mercury constantly keeps the same surface towards the Sun. One of us insists on adding here that the total solar eclipse of New Year's day, 1889, was visible in California, and that a month later gratified observers founded the Astronomical Society of the Pacific. The total solar eclipse visible in Guiana just before Christmas does not seem to have inspired a similar organization.

With all this we have not mentioned the items of 1889 that showed science at its most promising, to one observer at least. In 1917, a Hungarian writer, Louis Ilosvay de Nagy-Ilosva, predicted a glorious development of science after the Great War. He rested his case for creative post-war scientific activity on a list of discoveries made after the Franco–Prussian War. For 1889 he gave the invention of organotherapy by Charles-Édouard Brown-Séquard (testicular injections which B-S believed had rejuvenated him); the demonstration by Nathan Zuntz that albumin, carbohydrates and fats are equally usable by the muscles; and the foundation by Albert I of the oceanographic museum of Monaco.

It might seem trivial to celebrate so humble a thing as the rubber glove, but modern surgery would not be the same without it. Rubber gloves had been possible since the vulcanization of rubber

National Museum of Photography, Film and Television

"Jabez Hogg and Mr Johnson", a daguerreotype taken in c. 1843. The picture is the earliest known of a photographer at work. Hogg is timing the exposure with his watch, holding the lens cap in his other hand; the head of Mr Johnson is supported by a rest, to help him to keep still for an exposure lasting as long as a minute. It is not known what part the caged bird had in the proceedings.

became practicable from 1839 (**1.5**); indeed various surgeons and accoucheurs had advocated their use thereafter, generally to protect themselves from nasty diseases from which their patients might be suffering. But the continuous history of the surgical glove dates from 1889, when W. S. Halsted asked the Goodyear Company to make two pairs, with gauntlets, for his scrub nurse, Miss Caroline Hampton (who married him the following year). Their original purpose was to protect Miss Hampton's hands from the disinfectant to which she was allergic, but the wearing of gloves gradually caught on for surgeons as well.

Halsted was the first professor of surgery at the Johns Hopkins Hospital, which opened in 1889 in anticipation of the Johns Hopkins School of Medicine (1893). Theirs will be a lengthy celebration.

No centennial list would be complete without mention of the transmigration of souls. In 1889 there died Michel Eugène Chevreul, aged 103, Warren de la Rue, James Prescott Joule and Maria Mitchell. The same year saw the births of Sewell Wright (who lived almost to witness his own centennial), Lord Adrian, Dirk Coster, Ralph Fowler, Beno Gutenberg, Edwin Hubble, Ludwig Wittgenstein and the historian of science Hélène Metzger. We have not been able to discover with certainty which souls went where.

1839 (1.5 centenary)

Let us hope that the productive mixture of science and art that gave us photography recurs in celebrations of the sesquicentennial of its invention. In August of 1839 Louis Jacques Mandé Daguerre — born 1789 (**2.0**) — painter of panoramas, proprietor of the Paris and London Dioramas, and careful chemist, announced his process for sensitizing metal plates, exposing them to light and fixing the latent image. The same year, William Henry Fox Talbot, Cambridge wrangler, philologist and frustrated landscape painter, made known his process for taking negative images on treated paper. Many far-reaching improvements perfected in the next half-century made photography an indispensable tool of science. By 1889 (**1.0**) the physiologist Étienne-Jules Marey could determine with its aid that a fly in flight flaps its wings 288 times a second, a busy bee only 190 times, a lethargic butterfly 9 times. And the physicist Friedrich Neeson could propose to investigate the details of a more sinister sort of flight, the speed and spin of artillery shells.

American physicists will want to do honour to their first great theorist, J. Willard Gibbs, born 11 February 1839 in New Haven, Connecticut, where he spent all his life after returning in 1869 (**1.2**) from three years of study in Europe. He made himself known by sending his precise and difficult memoirs on thermodynamics and statistical mechanics to the leading European physical scientists. Maxwell, Rayleigh and Ostwald read and admired: Helmholtz, Planck and Einstein read not, and had to recover Gibbs's results independently, and with difficulty. Gibbs's years in Europe overlapped those of his exact contemporary, Aleksandr Grigorievich Stoletov, who became professor of physics at the University of Moscow. His best-known work, which established certain regularities of the then-new photoelectric effect, is eligible for centennial observance.

Prophetic observers in 1839 might have read into the official opening of the Physiological Institute at the University of Breslau something of moment. At the least, they would have known that it was the first physiological institute within the burgeoning German university system and that its director and leading light, Jan Evangelista Purkyně (died 1869, **1.2**), had already made a number of important physiological and histological discoveries. Like any serious microscopist of his day, Purkyně had availed himself of the improved accuracy of the achromatic microscope: "With boundless eagerness I investigated within the shortest time all areas of plant and animal histology and concluded that this new field was inexhaustible".

After 1839, Purkyně could make use of a systematic theory of cells, enunciated in that year by Theodor Schwann, whose *Mikroskopische Untersuchungen* capped what had been five amazing years of experimental productivity. Schwann's cell theory is not our cell theory, for he postulated that these basic units of living organisms can be formed by a process analogous to crystallization from a non-living soup he called the *blastema*. *Omnis cellula e cellula* came a little bit later, and not from Schwann. He himself returned to the Roman Catholicism of his fathers, discovered the "God of the heart, not of reason", and sought enlightenment through mystical insights into the nature of things. Appropriately the Microscopical Society of London (now graced with Royal blessing) was founded in that year of microscopical revelation.

Geologists will want to note the death, on 28 August 1839, of William Smith, the surveyor and stratigrapher whose maps did so much to establish historical geology and palaeontology. Like virtually all geologists in the discipline's heroic age, Smith travelled indefatigably, although confining himself to the British Isles. Sir Roderick Impey Murchison's *Silurian System* of the same year limited itself to Wales and the west of England, although Murchison possessively investigated Silurian remains in Russia and elsewhere. Another travelling naturalist, Charles Darwin, also burst upon the Victorian reading public with his *Journal of Researches*, though with little hint of the ideas that were later to revolutionize the study of the natural world.

Our preoccupation with the health of the ozone layer may promote a sesquicentennial for Christian Friedrich Schönbein — born 1799 (**1.9**) — who in 1839 identified the origin of the odour around electrostatic machines and electrolytic oxygen as a new sort of gas. He

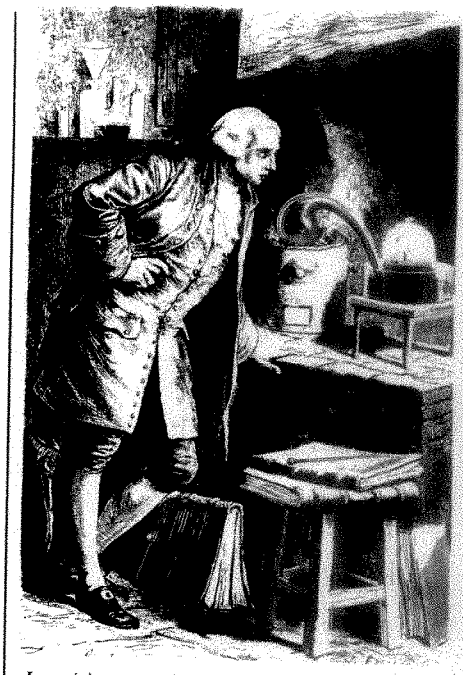
was then professor of physics and chemistry at the University of Basel, where he arrived following a curriculum vitae that included a strong dose of *Naturphilosophie* and an even stronger antidote, in the form of a year's stint as mathematics master at a boys' school in Epsom, Surrey. It took over a decade for Schönbein's colleagues to convince him that ozone is allotropic oxygen, and not, as he insisted, a chemical compound. As our next entry further illustrates, oxygen has not been an easy concept for its discoverers.

1789 (2.0 centenary)

Enlightened people wanted not only to talk well but also to talk correctly. French chemists shared and profited from this compulsion. In 1789 Antoine Laurent Lavoisier gave them a *Traité élémentaire de chimie* incorporating a nomenclature that was, in the buzz words of the Enlightenment, reasonable, natural and systematic. The revolution worked by his systematic vocabulary and the rules for applying it may best be illustrated by the substitution of words understandable by a modern chemist for terms now unintelligible, such as flowers of zinc and butter of arsenic. But just as even the most punctilious lexicographer sometimes fumbles etymologies, so Lavoisier invented some words that have proved unsuitable. Of these, 'oxygen', coined in the belief that dephlogisticated air is the principle of all acids, is perhaps the most interesting. Although Humphry Davy proved the etymology false in 1809–1810 (**1.8**) by demonstrating that muriatic acid (HCl) contains no oxygen, the misnomer survives. No one now has any difficulty with it; it is not necessary to know what a word means to use it correctly.

Another triumph of the natural and the systematic in 1789 was the publication of Antoine-Laurent de Jussieu's *Genera plantarum*, which presented botanists with an improved taxonomic system developed by the inbreeding of the ideas of three generations of Jussieus. This classification of flowering plants rested on correlation of a wide variety of characters and consideration of a very large number of specimens. Like Lavoisier's *Traité élémentaire*, Jussieu's *Genera plantarum* quickly became the cicerone in its field; although it has suffered many changes in its lower taxa, its arrangement of families has remained a part of botanical classification.

Jussieu was part of the increasingly professional tradition of French science, the Reverend Gilbert White a quintessential part of the amateur one in Britain. His book, *The Natural History and Antiquities of Selborne, in the County of Southampton* (1789), was a triumph of the local and parochial, couched with insight into the universal. Like Jane Austen, White lived through stirring times but mostly kept quiet about them. His observations on plants, birds, bats and his pet tortoise Timothy (who recognized the hand that fed him) continue to entertain, amuse and instruct.



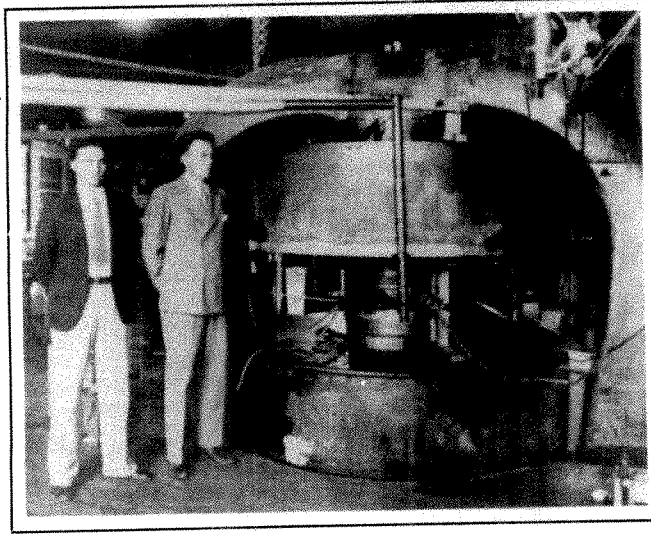
The year 1789 was a good one for the production of scientists named Bérard. Jacques Étienne Bérard, who died in 1869 (and so achieved a **2.0** and a **1.2**), is best known for his work with François Delaroche on the specific heats of gases at constant pressure. He later won a prize for discovering the effects of various gases on delaying the ripening of fruit. Joseph Frédéric Bérard, a physician, worked more in the classificatory and clarifying line. He began his short career with a *Plan d'une médecine naturelle*, and dedicated the rest of it to purging medicine of the misuse of words.

The greatest of French scientists born in 1789 was Augustin-Louis Cauchy, who gave the first comprehensive theory of complex numbers. His numbers were not his only complex. A little schizophrenia appears in his carrying to his first job, as engineer on the Napoleonic naval base at Cherbourg, Laplace's *Mécanique céleste* ("Sire, I have no use for that hypothesis") and Thomas à Kempis's *Imitatio christi*. In 1830 he chose religion over mathematics, refused the oath to the July monarchy, left his professorships and fled to the Jesuits in Fribourg. He returned to Paris in 1839 (**1.5**) and continued to pour out papers on all mathematical subjects; in less than 20 years no fewer than 589 (**14.0**) were published in the *Comptes Rendus* of the Paris Académie des Sciences.

1739 (2.5 centenary)

The year 1739 saw the foundation of the Swedish Academy of Sciences. It resembled the British, rather than the Continental, form of such societies in receiving from its king little more than the right to call itself royal. It emphasized practical arts as strongly as basic science. Among its earliest distinguished members were Anders Celsius, of the fixed-point centigrade thermometer (0° = temperature of boiling water and 100° = that of melting ice, a scheme that was later turned on its head); Carl Linnaeus, of the rigid-sex system of botanical classification; Mårten Triewald, who had learned his science and technology in England; and Emmanuel Swedenborg, who got his from angels. The Academy is now best known as the awarder of the Nobel prizes in physics and chemistry, and of the prize in Nobel's name in economics. In discharging this onerous responsibility, it can draw on 250 years' experience in balancing the pure and the applied, and on advice ranging from the angelic to the all-too-human.

The applied scientist might also celebrate 1739 for the publication of the second and last volume of Bernard Forest de Bélidor's *Architecture hydraulique*. This work rationalized civil engineering, in which shipbuilding and waterways then played a prominent part, with exemplary constructions and elementary arithmetic. Bélidor had previously written *La science des ingénieurs* — 1729 (**2.6**) — which deals almost exclusively with fortifications. It indicates an advance in professionalization, and also perhaps in civilization, that 'engineering' is no longer synonymous with 'military architecture'.



Lavoisier — prime mover in one revolution, victim of another.

1689 (3.0 centenary)

One of the greatest of all describers of disease, Thomas Sydenham (the 'English Hippocrates'), died on 29 December 1689. His happiest days had been spent as a young cavalry officer on the side of Parliament during the English Civil War, before settling down to become the leading London physician of his day. He described his own gout with especial feeling, but his portraits of smallpox, measles, hysteria and fevers mark him as a kind of Gilbert White of medicine. He brought an element of common sense into therapeutics, popularized the use of Peruvian Bark (which contains quinine) for intermittent fevers (the ague), invented a liquid preparation of opium (laudanum) and praised the value of fresh air and exercise. He had friends (including Robert Boyle and John Locke), but was not a clubbable man; above all, he believed in his own senses, which meant he had little truck with microscopes and other newfangled aids.

Consequently, Sydenham had no appreciation of the work of the Dutch lens grinder, Antoni van Leeuwenhoek, whose activity of 1689 included a study of the eye and the identification of the rods of the retina: seeing how we see. ▶

Lawrence Berkeley Laboratory

Man and machine — Ernest Orlando Lawrence (right) and the 37-inch cyclotron at the University of California, Berkeley, in 1936. This device was one of several of increasing power that Lawrence developed during the 1930s; his inventiveness was rewarded with the Nobel prize in physics for 1939.

1589 (4.0 centenary)

Armchair explorers should bestir themselves to celebrate the four hundredth anniversary of two books that immensely enlarged the knowledge and misinformation of the inquisitive reader of the late sixteenth century. One, Richard Hakluyt's *The principall navigations, voiages and discoveries of the English nation*, amounted to a handbook of the discoveries of the pushy navigators of Elizabethan England. Hakluyt understood the importance of acquainting his countrymen with the elements of geography; and for all the errors of his maps and reports, his readers knew more about the lie of the land than do most British and American high-school students, who cannot find London on a map or name the northern neighbour of the United States. The second mind-expanding book of 1589, Giambattista della Porta's *Magiae naturalis*, is a hodge-podge of recipes, parlour tricks, gee-whiz experiments and natural-philosophical claptrap. "Whatsoever was notable", says he, "and to be desired through the world, for curiosities and excellent things, I have abundantly found out"; which is the same principle on which this catalogue of anniversaries has been compiled.

1939 (0.5 centenary)

The fireworks have already started for the celebration of the fiftieth anniversary of the discovery of nuclear fission. As noticed in this column last year, Otto Hahn — born 1879 (**1.1**) — and Fritz Strassmann made and interpreted the critical radiochemical observations in December 1938. In February 1939, Lise Meitner and Otto Frisch — died 1979 (**0.1**) — published their idea of the physics at work, and appropriated the biological term 'fission'. Immediately physicists and journalists talked up the possibility of the practical application of atomic energy. Would it be Utopia or Armageddon? Also in February, Niels Bohr published his suggestion that the rare lighter isotope of uranium, uranium-235, was the source of the fission. It therefore appeared that the exploitation of the atom required the separation of heavy isotopes in bulk. Doubt about the possibility of effecting this separation persisted through the year, encouraging those who feared a bomb and frustrating those who hoped for power.

The Nobel prize in physics given during the bicentennial year of the Royal Swedish Academy of Sciences went to Ernest O. Lawrence for his invention of the cyclotron. By distinguishing the inventor of a machine and a method, rather than an investigator who made discoveries, the prize certified the arrival and the importance of the big, interdisciplinary, academic physics laboratory. The 1948 Nobel laureate for physiology or medicine was a chemist who made his observations in 1939. Paul Müller — born 1899 (**0.9**) — culminated his search for the perfect insecticide with the discovery that 4,4'-dichloro-diphenyl-trichloroethane satisfies many of the criteria. The patent on DDT, as he called it, was secured in 1940 and by the end of the Second World War the miracle chemical was available to help with programmes of insect control and disease eradication. The problems did not emerge until later. Other harbingers of the post-war world also appeared: in April 1939, RCA put its first television sets on the market; in August the German aircraft maker Heinkel flew the first jet aeroplane, too late to be operational for the Battle of Britain; and in December, a company incorporated to exploit Edwin H. Armstrong's patents for frequency-modulated radio, in good time to fight with RCA over the control of frequency bands.

It was already abundantly clear by 1939 that the war to end all wars had failed. Among those who did not live to see the horror of the coming years were Sigmund Freud, Harvey Cushing, Karl Friedrich von Auwers, George Barger, Frank Dyson, Søren Sørensen, Floyd Richtmyer and E. B. Wilson.

1914 and 1964 (0.5 ± 0.25 centenaries)

The celebrated experiments of James Franck — died 1964 (**0.25**) — and Heinrich Hertz, in which they measured the excitation potential of mercury vapour, took place in 1914. The fact that they at first misinterpreted their results as ionization potentials and hence as fatal to Bohr's new theory of the atom is less celebrated. In 1926 they received the Nobel prize "for their discovery of the laws governing the impact of an electron upon an atom", that is, for confirming Bohr's ideas. The detection of the omega minus meson in 1964 represents an entirely different sort of discovery, one driven by a theoretical prediction, in this case the system of quarks which won the Nobel prize for 1969 (**0.20**) for its inventor, Murray Gell-Mann — born 1929 (**0.60**). The discovery of CP violation, which also took place in 1964, showed that nature had not yet run out of surprises.

The Japanese contribution to modern science has been substantial. Many of the earliest pioneers who sailed from the Land of the Rising Sun to Europe went to learn the latest bacteriological techniques. Among them were Sahachiro Hata, Hideyo Nogouchi and Shibasaburo Kitasato. The latter worked with both Koch and von Behring and was the founder, in 1914, of the Kitasato Institute in Tokyo. On Christmas Day of the same year, in far-off Rochester, Minnesota, E. C. Kendall crystallized a substance which he called thyroxin. Crude thyroid extract was already used therapeutically but Kendall's achievement was to make possible the synthesis and elucidation of the molecular structure of the active thyroid substance. Kendall shared the Nobel prize in 1950: not for this research, important though it was, but for his work, with Philip Hench, on the isolation and therapeutic uses of 'Compound E' (cortisone), reported by them in 1949 (**0.4**).

We end, as we began, with the gargantuan. In 1914 the Panama Canal admitted its first ships after a decade of digging. Its completion required the conquest of yellow fever and the removal of 240 million cubic yards of earth. In 1964, the Verrazano Narrows Bridge, begun in 1959 (**0.3**), the longest single-suspension span in the world, opened for traffic. Each of its towers contains steel enough to make 18,000 automobiles, big ones, 1964-vintage; the entire structure weighs almost four times more than the Empire State Building. The atomic bomb exploded that year by the Chinese — their first — would have destroyed both the building and the bridge, had it been tested in Manhattan. □

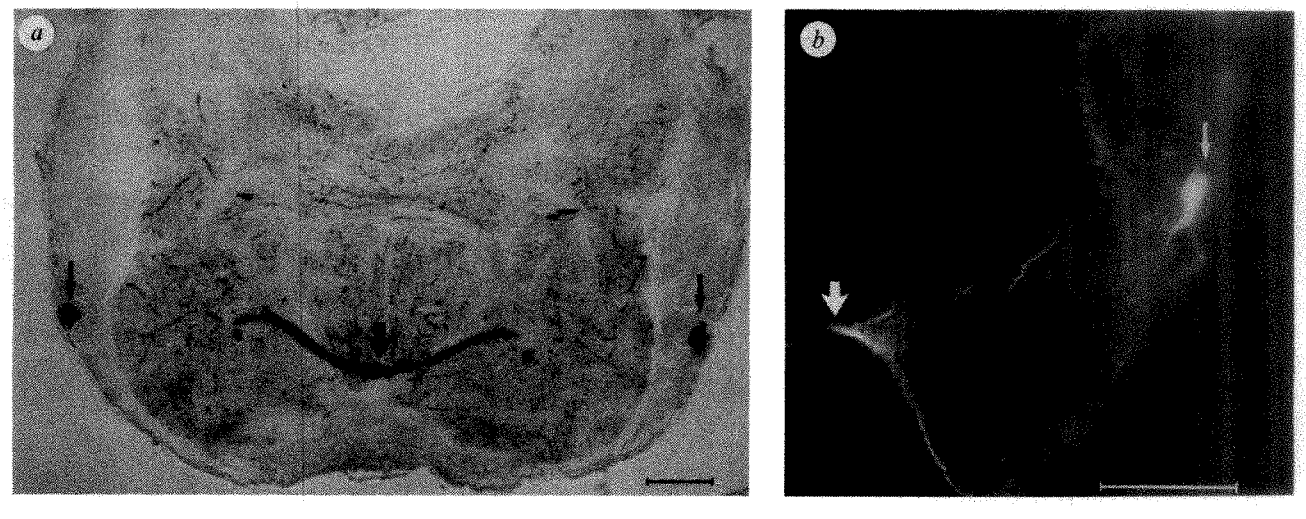
Chemical codes for the control of behaviour in arthropods

Gerd Bicker & Randolf Menzel

Institut für Tierphysiologie-Neurobiologie, Königin-Luise-Str. 28/30, D-1000 Berlin 33, FRG

Neuromodulators and hormones elicit and modify well-defined behaviours. Their mode of action can be studied to advantage in arthropods, where the natural releasing cells and neuronal target circuits are concisely identified. The coordinated actions of biogenic amines and peptides on both central and peripheral neural activity and metabolic processes bias the whole organism to perform a coherent behavioural routine.

THE Greek physician Galen believed that the brain, with its fluid-filled cavities, was mainly a secretory organ that regulated all aspects of health, mood and nervous function. The modern view of the brain stresses that its computational tasks are based on the connections between its constituent nerve cells. But chemistry plays a vital role in expressing this connectivity, the extent of which is only just being appreciated. Although the importance of chemical transmitters for mediating information transfer at the synaptic connections between neurons is well established, in the past few years it has become apparent that this transmission can be altered or modulated by other chemicals, also produced by neurons, known as neuromodulators.



The actions of neuromodulators at the cellular level and their effects on behaviour are known in some detail but it has been difficult to bridge the gap between these two levels. Here we review recent work on crustaceans and insects which is demonstrating how modulators affect the connectivity in neural circuits, tuning and orchestrating their outputs to fit the immediate needs of the animal.

The production of behavioural sequences requires the temporal and spatial coordination of many neural circuits. In addition, there has to be flexibility in the ways in which circuits can be combined because sensory, central and motor neurons can participate in various combinations in many different behaviour patterns. The work in crustaceans and insects is showing that neuromodulators promote this plasticity by concordantly altering the responsiveness of neurons and muscles, together with changes in metabolism. Through the interplay of several modulators, basic circuitry can be allocated in a variety of ways at different times.

Transmitters, modulators and hormones

The 'classical' transmitters such as acetylcholine, glutamate and GABA directly affect the operation of ion channels and thus rapidly either excite or inhibit the postsynaptic cell. In contrast, the neuromodulators, which include biogenic amines and peptides, act indirectly on the ion channels, modifying their responses to the classical transmitters on a longer time scale. The neurohormones, a third class of chemical messengers, work in a similar way to the modulators, but usually over yet longer times and on targets at a distance from their release sites.

In mammals, neuromodulators and neurohormones are involved in generating specific behavioural states; experimental alteration of neuromodulator levels can evoke specific body movements, postures and motivational states, and alter sensory processing. For example, depletion of the biogenic amine 5-hydroxytryptamine (5-HT, or serotonin) in the brain leads to an increase in arousal and motor activity, evidence that 5-HT normally has a depressing or braking effect on behaviour[1]. On the other hand, stimulation of pathways that release another biogenic amine, noradrenaline, increases activity and may

Neurons in the insect nervous system can be identified by a combination of immunohistochemistry and intracellular injection of a fluorescent dye marker. *a*, Serially homologous neurons in the suboesophageal ganglion of the bee that react with antibodies to 5-HT (peroxidase-antiperoxidase reaction). *b*, One of these neurons after intracellular injection with Lucifer yellow. Subsequent processing of this preparation with antibodies to 5-HT confirms that this is one of the neurons shown in *a*. These neurons may be involved in modulating the proboscis-extension reflex, discussed on page 37. Scale bar, 50 μm. Small arrows: cell bodies; broad arrows: commissural fibres. Fig. 1 Schematic drawing showing the organization of the segmented insect nervous system (*a*) and some pathways for information flow (*a* and *b*). The insect nervous system serves as a model of the arthropod nervous system, which consists of an anterior cerebrum (brain) and a ventral chain of segmented ganglia joined by paired connectives. The brain processes sensory information from the retina of the compound eye in the optic lobes and from sensory receptors on the antenna in the antennal lobe. Multimodal integration takes place in more central neuropiles, for example, the mushroom bodies, the output of which is transmitted to the motor centres of the ventral nerve cord by descending interneurons. The brain is linked by paired connectives to the suboesophageal ganglion (Sog) and connects to the hormone-producing neurohaemal organs, the corpora cardiaca (CC) and corpora allata (CA). The suboesophageal ganglion contains the motor circuits for feeding and collaborates with the brain in the initiation, maintenance and coordination of behaviours[71]. The ganglia of the ventral nerve cord contain the neural circuitry controlling behaviours such as flight, jumping, respiration, stridulation and oviposition, including the motor neurons that form the outputs to the muscles. These ganglia communicate with the brain through ascending neurons, so that the flow of information in the segmented nervous system is organized in a loop-like fashion[71]. Some identified classes of monoaminergic neurons interconnecting several neuropilar compartments, or even segments, are shown schematically in *b*. These include several 5-HT-immunoreactive neurons (5-HT-ir) in the optic lobes[72], a descending interneuron in the antennal lobe (DCG)[68] and segmentally homologous neurons (SH)[68,73]; and a cluster of octopamine-containing unpaired median DUM neurons[27-30] in each of the thoracic ganglia. Arrows indicate synaptic output areas; thickening of neurites indicates areas of synaptic input. Ant, anterior.

facilitate learning by acting on selective attention or alternatively on stimulus reinforcement[2]. The circuitry in the mammalian brain that regulates these behaviours is, however, so complex that it is difficult to investigate the facilitatory or depressing effects of a neuromodulator in terms of its influence on specific synaptic connections.

Arthropod preparations

In animals such as the crayfish, the lobster and various insects, the circuitry is much more accessible and the cellular mechanisms by which neuromodulators induce behavioural changes can be investigated directly. These animals display some sophisticated behaviours, the generation of which is reasonably well understood at the neuronal level.

The arthropod central nervous system (Fig. 1) is built on a clearly segmented plan and contains many neurons that can reliably be identified from one preparation to another. These are amenable to intracellular microelectrode recording and network analysis, and the interactions between modulatory substances and their target neurons and muscles can be studied on a cell-by-cell basis. In vertebrates the only comparable studies are of very simple behaviours, such as swimming in the lamprey[3].

Modulation of rapid-response circuits

In several invertebrate species the experimental activation of single interneurons can initiate complete behavioural acts. One of the best studied examples is the escape behaviour of the crayfish, which begins with a tail flip that propels the animals away from strong tactile stimulation of the tail fan at the end of the abdomen[4,5]. The inputs from the sensory receptors on the tail fan connect either directly or through a group of sensory interneurons with the lateral giant fibres that mediate the tail-flip response (Fig. 2*a*). When the tail fan is touched, the inputs evoke action potentials in the lateral giant fibres that in turn excite the motor neurons that drive the flexor muscles of the abdomen. The resulting tail flip pitches the animal away from the source of stimulation[4].

The threshold for triggering the response varies with the behavioural context: it becomes more difficult to evoke a tail flip when a crayfish is restrained or when it is feeding, and the threshold for triggering action potentials in the lateral giant neurons goes up under these conditions. In the sensory pathways, sensitivity can be altered by repeated tactile stimulation which leads to a gradual decrease in the probability that the reflex will occur. This so-called habituation results from depression of the synaptic transmission between the tactile input neurons and sensory interneurons[4]. Conversely, the probability of eliciting a tail flip can be enhanced or sensitized, if the animal is subjected to strong electric shocks, because the firing threshold in the largest sensory interneuron decreases[6].

Both habituation and sensitization can be mimicked by applying biogenic amines to the nervous system: 5-HT reproduces the depressive effects of habituation, whereas octopamine mimics the sensitization produced by a traumatic stimulus. Neither amine elicits or affects the performance of the escape behaviours but, rather, they modulate synaptic transmission in the sensory circuits. The excitatory postsynaptic potentials in the lateral giants produced by stimulating sensory neurons are reduced when 5-HT is perfused through the arterial system and enhanced by octopamine perfusion[7] (Fig. 2*a*); destroying cells that are immunoreactive for 5-HT with a specific neurotoxin also removes the inhibitory effect of 5-HT on transmission at the synapses[8]. From such results, it can be assumed that 5-HT and octopamine have modulatory roles in the escape response.

Once it is initiated by the firing of the giant fibres, the escape response goes automatically to completion, so it seems reasonable that only the synapses in the input circuits should be modifiable. In other behaviours, such as aggressive and submissive postures in the lobster, several levels both centrally and peripherally are modulated simultaneously[9,10]. The injection of

5-HT into freely moving lobsters evokes a sustained flexion of limbs and abdomen resulting in an aggressive-looking stance, whereas injection of octopamine leads to sustained extension producing a submissive-looking posture[9,10]. The posture evoked by 5-HT results from the contraction of the postural flexor muscles, whereas octopamine produces contraction of the antagonistic extensors. Application of both amines at the peripheral synapses between motor neurons and muscles, however, induces a more vigorous response in both flexors and extensors, so the antagonistic actions of the two amines must result from modulation of circuits in the CNS (Fig. 2*b*). Electrophysiological recordings show that the spike frequency in flexor motor neurons is increased by 5-HT and decreased by octopamine, and vice versa in the extensor motor neurons. A corresponding antagonism is also found in the excitatory and inhibitory motor neurons that innervate each muscle (unlike vertebrates, arthropods have direct inhibitory innervation of their muscles).

Immunohistochemistry shows over 100 cells reacting with antibodies raised against 5-HT, widely distributed throughout the nervous system; experimental attention has focussed on two pairs of these neurons that have cell bodies in the first abdominal ganglion and fifth thoracic ganglion (Fig. 2*c*). Their morphology[11] provides some insight into how the opposing motor patterns could be coordinated by actions at both central and peripheral sites: each has two separate sets of endings, one in the peripheral neurosecretory tissue, where chemicals released can enter the blood, and the other in the neuropiles of the CNS, where integration of information for the activation of the flexor motor programme takes place. The specificity for the action of the amine must be in the CNS, whereas the periphery is simply primed to be more responsive to the central command[9-11].

Modulation of transmission at the neuromuscular junction may be quite widespread. Cockroaches, locusts and crayfish all have some motor neurons that release the pentapeptide proctolin[12-14], as well as a classical excitatory transmitter, which is probably glutamate[15-17]. Proctolin does not depolarize the muscle membrane if applied alone; even though its detailed action is different in each animal, its general affects are to enhance contractions evoked by application of glutamate, or to cause sustained tension instead of a rapid twitch.

Selection of activity patterns

Many rhythmic behaviours result from patterns of activity in central pattern generators (CPGs) which consist of neuronal circuits capable of producing motor output patterns in the absence of sensory feedback. Sensory inputs are nevertheless essential for the activation and shaping of a precisely coordinated motor output. In the lobster, food is ground by three teeth in the anterior part of the stomach, known as the gastric mill, and is then pumped and filtered by the rhythmic constrictions and dilations of the posterior or pyloric end of the stomach. The muscles involved in the movements of the stomach are controlled by a CPG of about 30 neurons located in a small nerve centre termed the stomatogastric ganglion, together with some neurons in the commissural ganglia[18,19]. The rhythm-generating circuits in the stomatogastric ganglion are capable of producing many different output patterns in response to different transmitters in the input fibres[19,20] (Fig. 3), allowing a cellular analysis of the interactions between neuromodulators and their target neurons. Using an endoscope and video recordings, rhythmic patterns in the outputs of the isolated stomatogastric ganglion have been related to the movements of the gastric teeth in the intact animals[21]. Injections of proctolin into the blood of an intact animal alters the integration in the CPG circuit in such a way that several modes of chewing and grinding movements are produced in a dose-dependent manner. Neuromodulators such as proctolin may not only influence which output is produced but also modulate the strength of the interaction between the gastric and pyloric burst-generating

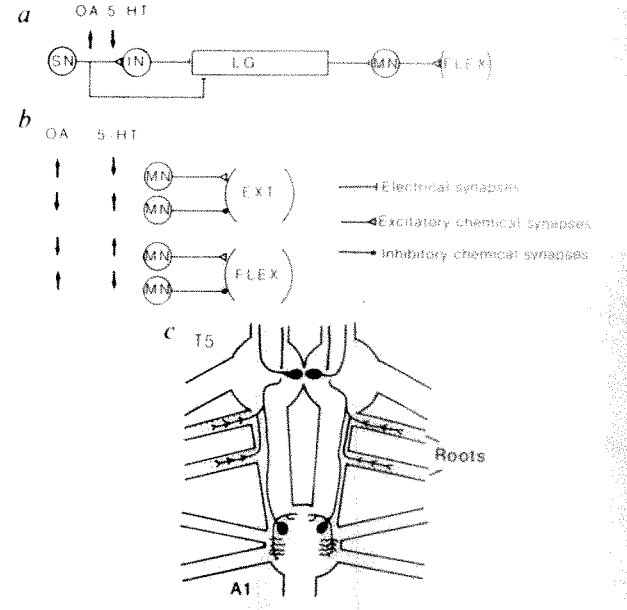

Fig. 2 Neuromodulation of rapid response circuits in crustaceans. *a*, In the crayfish tail-flip circuit, transmission at the synapses between the sensory neurons on the tail fan and the sensory interneurons is enhanced by octopamine and depressed by 5-HT and thus alters the threshold of the tail-flip response to tactile stimulation of the tail fan. *b*, Modulation of aggressive and submissive postures in the lobster by octopamine and 5-HT. The two amines have opposing effects on the excitation of the motor neurons of the flexon and extensor muscles. *c*, Schematic drawing of 5-HT immunoreactive cells in the lobster, with somata in the first abdominal ganglion (A1) or the fifth thoracic ganglion (T5). The cells innervate two separate release sites (stippled), a peripheral neurosecretory site in the nerve roots and central sites in the neuropile of the ganglion. circuits in the stomatogastric ganglion, thus promoting the integrated activity of the stomach when dealing with foods of different qualities.

Orchestration of behavioural units

Fully coordinated sequences of behaviour in several insects can be released by the injection of transmitters or their analogues either into the haemolymph or directly into the nervous system. In general, octopamine has a releasing or enhancing effect that is opposed by 5-HT.

Octopamine not only promotes the expression of a behaviour in insects but also helps to integrate performance at several levels of organization. In restrained locusts, for example, flight motor activity can be initiated by the iontophoretic application of octopamine into the neuropile of the metathoracic ganglion[22,23]. Octopamine also influences the kinetics of contraction in flight muscles[24,25], resulting in an energy saving increase in power output. During long flight sequences, octopamine induces the release of the adipokinetic hormones from stores in the corpora cardiaca, resulting in mobilization of lipid (see Fig. 1)[26]. Thus, this biogenic amine not only induces flight motor activity in the CNS but also mobilizes the metabolic fuel required for flight.

The main candidates for neurons that release octopamine in the ventral nerve cord of locusts are a group of approximately 90 dorsal unpaired median (DUM) neurons (Fig. 1). Most of these are local interneurons but a few of the larger cells have axons that bifurcate to innervate the musculature on both sides of the body[27-30]. Sombati and Hoyle[22] proposed that the release of octopamine from DUM neurons is causally related to the initiation and modulation of behaviour, because iontophoretical

administration in the appropriate ganglia elicits flight or rhythmic stepping movements of the legs, or suppresses the abdominal digging rhythm used by females during egg laying. As electrical stimulation of single DUM cells does not elicit any behaviour[22,31], the probability that a behaviour will occur may depend on the pattern of activity over the whole population of DUM cells. The resulting pattern of release in the neuropile could thus determine "which parts of which circuits are most likely to be thrown into (or out of) action"—the so-called orchestration hypothesis[22].

Indeed, application of octopamine and its receptor agonists, such as the formamidines, have strong behavioural effects; nocturnal moths become hyperactive during daytime[32], the male cabbage looper moth becomes hypersensitive to the olfactory signal that induces sex-pheremone mediated flight, and engorged ticks detach from their hosts[34]. In the fly and the bee, octopamine or its agonists enhances the reflex response to stimulation of sugar receptors on the feet or antennae with sucrose and causes the animals to feed twice as much as the controls (refs 35, 36 and R.M. and P. Schulz, unpublished results). Because formamidines disturb behavioural co-ordination[37-38], they may prove to be potent insecticides.

The antagonistic effects of octopamine and 5-HT have been demonstrated by injecting the amines into the haemolymph in several preparations. Octopamine and 5-HT induce opposite postures in males of the cabbage looper moth when they attempt to take off to fly in response to a sex pheromone[33]. In honeybees the two biogenic amines may act antagonistically in the visual system. In response to moved striped patterns, bees make direction-specific adjustments of antennal position, a reflex which is enhanced by application of octopamine and reduced by 5-HT in a dose-dependent fashion[39]. In flight behaviour, different amines may regulate different aspects of the control system: in the hawkmoth *Manduca*, octopamine evokes flight sequences, presumably by enhancing the efficacy of sensory transmission, whereas dopamine seems to have a direct excitatory effect on the interneurons of the flight motor and 5-HT surpresses flight motor output[40].

Hormonal orchestration of development

The natural release of hormones during the life cycle of an animal provides the most striking examples of the orchestration of behaviour by circulating chemicals over a time span of hours to days. In insects, hormone levels are known to affect reproductive behaviours, such as courtship in crickets[41] or the division of labour in the honeybee hive[42].

A cellular approach to hormone-mediated behavioural changes during development has been possible in the moth *Manduca*, which undergoes a complete metamorphosis from the larval or caterpillar stage, through the pupa to the adult[43,44]. The transition through the various stages is regulated by the relative levels of ecdysteroid hormones and juvenile hormones in the haemolymph. A third hormone, eclosion hormone, regulates the final shedding of the pupal cuticle and emergence of the adult, a process termed eclosion. This consists of two phases, the splitting of the cuticle over the thorax by rhythmic movements of the wing bases; and peristaltic waves of the abdomen, which propel the shed cuticle posteriorly. Both phases are centrally programmed, because the appropriate motor patterns can be triggered when the isolated nerve cord is exposed to eclosion hormone.

The nervous system is sensitive to eclosion hormone only shortly before the normal time of hatching. A circadian clock in the brain gates the release of eclosion hormone from neurosecretory centres located in the brain[43,44]. Eclosion hormone is released as a pulse 2.5 hours before the adult emerges and during this period neurons in the nerve cord become sensitive to the hormone as they start to express two proteins that may be required for the transduction of its signal[45]. The control of the expression of these protein requires the presence of

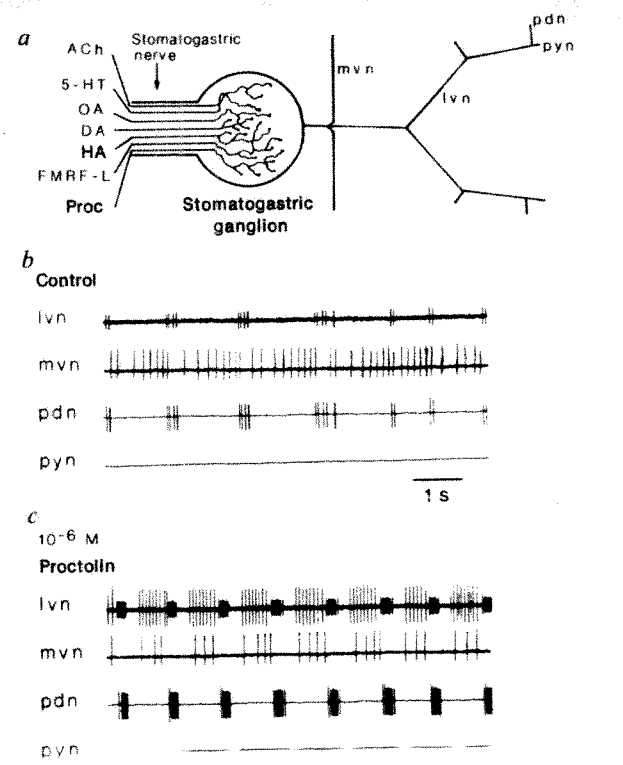

Fig. 3 Neuromodulation of rhythmic motor output of the crustacean stomatogastric nervous system, which control the coordination of the muscles of the stomach. *a*, The stomatogastric nerve carries inputs to the stomatogastric ganglion from other ganglia that use a variety of transmitters. Each transmitter elicits a different motor pattern. Approximately half the cells in the stomatogastric ganglion contribute to the central pattern generator (CPG) for the rhythm of the gastric mill and about the same to that for the pyloric rhythm, both of which can be activated in the isolated ganglion. There is only one interneuron in each of the gastric and pyloric CPGs; the rest of the neurons of the CPGs are motor neurons. The pyloric pattern is an emergent property of the synaptic connections and membrane properties in the network of interneuron and motoneurons and the pacemaker activity of the anterior burster interneuron[18,19]. *b*, An example of pyloric motor patterns generated by the isolated ganglion, recorded extracellularly from the median ventricular nerve (mvn), lateral ventricular nerve (lvn), pyloric dilator (pdn), and pyloric nerve (pn) shows the modulation of the pyloric rhythm (*c*) when proctolin is added to the bath. It produces an increase in cycle frequency and a change in phase relations in the firing of pyloric motor neurons, which would result in a different pattern of contraction in the pyloric muscles (20). Comparing the effect of proctolin on synaptically isolated neurons with those in the intact network shows that the modulatory effect cannot solely be attributed to direct effects on pyloric neurons (20). Rather, the response of the circuit is shaped by connectivity among neurons that are directly affected and those that are unmodulated ACh: acetylcholine; 5-HT: serotonin; OA: octopamine; DA: dopamine; HA: histamine; FRMF-L: FRMF-like peptide; Proc: proctolin. Modified after refs 19, 20.

ecdysteroid hormone, but also its subsequent removal[46]. Timing is also essential for the sequential activation of the two phases of eclosion behaviour, brought about by a different latency of the action of eclosion hormone on the motor circuits controlling the two phases.

If the pupal cuticle is peeled off before the animal enters the eclosion period, adult behaviours such as walking and the righting reflexes are absent. These appear with a delay of several hours if the eclosion hormone is injected, transforming the prematurely born, uncoordinated animal into an adult with a normal behavioural repertoire[43]. The changing levels of hormones thus orchestrate profound cellular changes during post-embryonic development that are manifested in stage-specific behaviours. And not only do they affect the responses of neurons

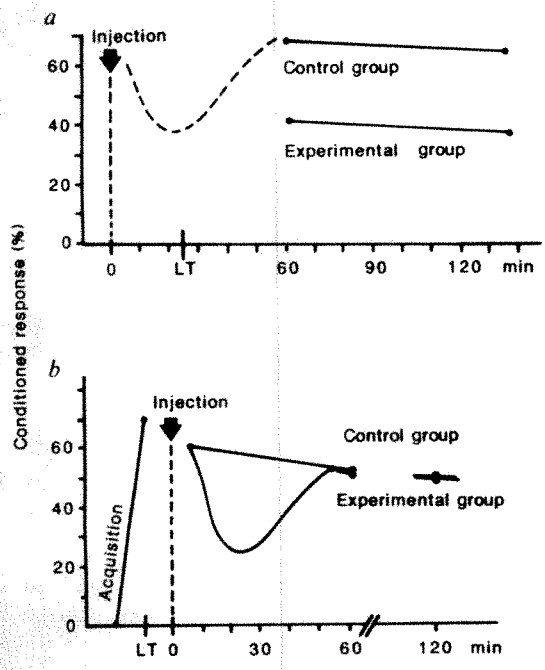

Fig. 4 The experimental procedures used to study the effect of drugs injected into the brain of the honeybee on learning, memory and retrieval from memory. The basic learning procedure is to test a group of bees for their spontaneous responses to an odour and then to condition the non-responding animals once to this odour by pairing the odour with sucrose solution (the learning trial, LT). After conditioning, about 70% of the animals extend the proboscis to the presentation of the odour alone. *a*, Storage test: to see whether a drug interferes with the formation of memory, it is injected before the learning trial. After the drug or a saline control is injected, the animals are conditioned by one trial (LT) at the time when the action of the drug is optimal, as determined in the recall test (see below; dotted curved line indicates that this is a background effect not particularly tested in this experiment). The repeated presentations of odour alone follow when the immediate effect of the drug has vanished. The example given is for an injection of 5-HT (10^{-8} M, 5 nl) into each α lobe of the mushroom bodies (see Fig. 5): the experimental animal shows a persistent reduction in the conditioned response. This proves that 5-HT injected into the α lobe interferes disruptively with the formation of a memory trace. Other drugs like octopamine or noradrenaline may persistently improve the memory when injected before the conditioning trial (see Fig. 5, unpublished results reproduced by kind permission of M. Sugawa). *b*, Retrieval test: the drug is injected into the brain after the learning trial and the animals are tested by repeatedly presenting the odour stimulus alone. The control group (same amount of saline injected) shows a small decline in response, the extinction effect, which is due to repeated testing. The experimental group transiently responds less but the effect of the drug disappears at longer intervals. The example given here is for dopamine (10^{-6} M, 100 nl injected into the protocerebrum), which inhibits conditioned responding maximally at 20–30 min after injection. The animals can be successfully conditioned at a time when the action of dopamine is optimal, showing that the dopamine injection does not interfere with the sensory or motor components or those underlying memory formation[61].

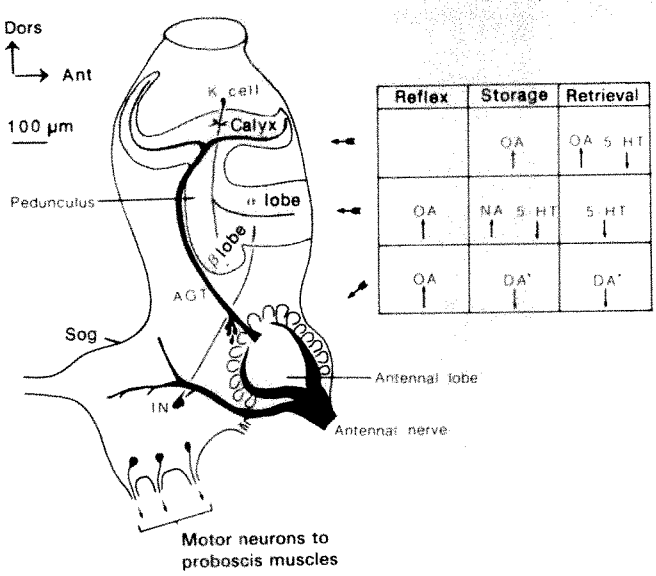
to hormones: they also influence remodelling of neuronal circuits by incorporation of new neurons, reorganization of neuronal arborizations and cell death[47].

Behavioural plasticity and learning

As neuromodulators confer flexibility on neuronal circuits and trigger intracellular biochemical events that outlast the signal, they have been implicated in learning, memory and the performance of learned tasks in vertebrates[48–50], molluscs[51,52] and fruit flies[38,53,54]. There is some debate, however, about the site of modulatory action in associative learning.

Classical conditioning is a type of associative learning in which an animal establishes a connection between a neutral conditioned stimulus (CS), for example, a sound or coloured light and a reinforcing unconditioned stimulus (US) such as food. The repeated temporal pairing of the two stimuli during training elicits a response to presentation of the initially neutral stimulus that is normally caused only by the US. The association of events during classical conditioning requires a locus in the nervous system where the US and CS can converge. An analysis of classical conditioning at the cellular level in the mollusc *Aplysia* has pinpointed an allosteric regulation of an enzyme, membrane-bound adenylyl cyclase, as the most likely point of convergence[51]. It is stimulated by the release of a neuromodulator, 5-HT, in the US pathway and its activity is amplified by activity in the CS pathway, which increases intracellular calcium levels.



Some studies in the vertebrate literature, however, consider the US and CS pathways separately from the modulatory functions of biogenic amines, which are assumed to regulate affective states and thus are seen as a third and independent component in the neural substrate of learning[55,56]. Amines are thought to cause an arousal state in the memory-forming part of the nervous system, so directing 'attention' to the conjugation of stimuli.

The honeybee provides an excellent preparation for addressing this question[57–62]. Under restrained conditions in the laboratory a memory lasting for days is produced after a single trial in which the CS is an odour, paired with a sucrose reward as the US[63]. The animal extends its tongue (proboscis), its normal response to sucrose, as a conditioned response (CR) when an initially neutral odour stimulus is presented[57,64]. This learning process can be manipulated by global or local injections of small quantities of drugs (around 5 nl) directly into the brain. As learning occurs in a single trial that lasts only a few seconds, drugs can be used to separate memory formation from memory retrieval, particularly to examine the unresolved question of whether these are conceptually separate processes. By injecting drugs before the learning trial, storage can be disrupted; injection after the trial disrupts retrieval (Fig. 4).

As an example, consider the action of a global injection of dopamine (10^{-6} M). If it is injected before the learning trial and the animals are tested at a time when the action of dopamine should be optimal (storage test), learning is not impaired but injections after the learning trial (retrieval test, Fig. 4), induces a transient reduction in the conditioned response to the presentation of the CS alone[58,59,61]. Thus, dopamine interferes selectively with the retrieval process. Because performance in the storage test is unchanged, dopamine has no effect on olfactory coding, motor response or memory storage. In contrast, injections of amines such as 5-HT interfere with the storage process (Fig. 4*a*) leading to irreversible effects in the conditioned response[65]. As the motor performance during the period when the action of 5-HT is optimal is unaltered, 5-HT must interfere with the storage processes, not with the sensory or motor components of the task.

Local injections of biogenic amines into particular regions of the brain reveal a different pattern of action for each modulator that depends on the area injected and the behavioural components tested[62] (Fig. 5). For example, in the chemosensory processing area, the antennal lobes, octopamine seems to be involved in stimulus reinforcement. In the higher association areas, the mushroom bodies, octopamine enhances both memory storage and retrieval, whereas noradrenaline enhances only storage and only when injected into the output areas of the mushroom bodies. The facilitatory effects of both octopamine and noradrenaline are antagonized by 5-HT (see Fig. 5 legend for more details).

The most important outcome of these experiments is that learning and retrieval can be improved or depressed by different amines acting at different locations and at different times in the learning process. The experiments also support earlier conclusions[65,66] that the memory system in the bee brain involves

Reflex	Storage	Retrieval
	OA ↑	OA ↑ 5-HT ↓
OA ↑	NA ↑ 5-HT ↓	5-HT ↓
OA ↑	DA* ↑	DA* ↑

Fig. 5 The effect of local drug injections on the proboscis-extension reflex and on storage and recall of the conditioned response during olfactory learning in honeybees is summarized on a schematic side view of the main pathways in the brain and suboesophageal ganglion (Sog) mediating the proboscis extension reflex. Chemosensory afferents from the antenna terminate in the glomeruli of the antennal lobe. Relay neurons transmit olfactory information through the antenno-glomerular tract (AGT) into the calyx of the mushroom body. The mushroom body (stippled) contains approximately 170,000 intrinsic Kenyon cells (K cell), which project from the calyx to the two output regions, the α- and β-lobe[74]. Monoaminergic interneurons (IN) connect the suboesophageal ganglion with neuropiles around the α- and β-lobes. The suboesophageal ganglion contains the motor circuits and motor neurons responsible for the extension of the proboscis. The table summarizes the action of locally injected amines on the three components of behaviour—proboscis extension reflex, storage and recall. In the table, the arrows pointing upwards indicate facilitation of the reflex or conditioned response, those pointing downwards indicate a reduction. Bold arrows indicate the injection sites. Octopamine (OA) mimics the sensitizing action of the US (sucrose stimulus) and stimulates feeding behaviour when injected into the antennal lobe, suggesting octopamine has a role in reinforcement. If OA is injected into the pedunculus of the mushroom bodies close to the input synapses of the chemosensory relay neurons in the calyx, no changes are found in the reflex performance but both components of learning, memory formation and recall are enhanced. OA has no effect when injected into the output regions of the mushroom body, the α-lobes, whereas noradrenaline (NA) injections into this region enhance memory formation, particularly in animals with lower learning rates. 5-HT on the other hand antagonizes the facilitatory actions of OA and NA in the mushroom body but does not affect the non-associative modulation of the reflex. The substances (2.5 nl, 10^{-6}–10^{-8} M) were injected into either both antennal lobes, or both α-lobes or both pedunculi (Pd) of the mushroom bodies (the volume of the brains is ~1 μl). The drug effects were compared with control animals which were injected at the same sites with the same volumes of saline. Several hundred animals were tested[58,62]. Data for DA* from 60. Dors, Dorsal; Ant, anterior (orientations refer to the position of the brain in the head in life).

several regions, with non-associative modulation of the feeding reflex taking place in the antennal lobes, whereas the mushroom bodies, an area thought in other insect species to be involved in the coordination of behaviour patterns[67], are necessary for the long-term formation and read out of associative memory. Identified neurons immunoreactive for 5-HT that link these areas have been impaled with dye-filled electrodes[68], so it should be possible to analyse the learning capabilities of an insect brain at the cellular level.

The distinction between storage and retrieval mechanisms implies that the location of the memory trace is not the direct sensory pathway between the chemosensory afferents of the antennae and the motor circuit for the proboscis response in the suboesophageal ganglion (Fig. 5), because this pathway remains functional when the conditioned response is blocked pharmacologically. Anatomical studies reveal prominent fibre tracts that leave the direct sensory pathway and enter the mushroom bodies (Fig. 5). Storage of the memory trace in a pathway parallel to the main sensory–motor path contrasts the memory system of the bee with the model developed for associative and non-associative plasticity in molluscs, where activity-dependent modulation has been found at the synapses between sensory and motor neurons[51].

Chemical codes and behaviour

Both vertebrate and invertebrate nervous systems contain neurons with widespread branching patterns that seem suitable for coordinating neural activity in a large population of follower cells by a rather diffuse release of neuromodulatory substances. The investigation of some of these identified cells and their targets in arthropod nervous systems suggests that neuromodulators orchestrate behaviour by acting simultaneously at many synaptic levels in the nervous system to integrate neuronal activity, and also by more widespread regulation of metabolism. Sensory circuits may be sensitized or depressed, motor circuits can be biased towards favourable states, muscle tone is adjusted to the correct set point and the metabolism fuelling the muscle power is activated. This coordination of neuronal activity in different parts of the organism has also been observed in molluscs[69] and leeches[70], where identified amine-containing neurons integrate several appetitive and comsummatory components of feeding behaviour, such as food arousal, swimming toward food sources, bite frequency and meal size.

Experimental manipulation using neuromodulators or their analogues to mimic the natural release of neuromodulators can evoke coherent behaviour. The chemical code for regulating behaviour arises from the patterns of release of the various modulatory substances. These in turn are decoded by the distribution in the target tissue of receptors specific for each type of modulator. As the receptors are linked to the intracellular biochemical signalling pathways, the neuromodulators can modify the excitability of nerve cells on a longer time scale than that of conventional rapid synaptic transmission, leading to longer lasting functional changes in neural circuitry that serve processes such as arousal, selective attention, reinforcement and retention of memory.

Although the behavioural responses to neuromodulators are becoming increasingly better understood, the sensory pathways for activating neuromodulatory neurons are an enigma. A great deal of circuit chasing remains to be done to establish the connectivity between these neurons and external sense organs. Electrophysiological recordings from neuromodulatory neurons of motor circuits[11,22,31] has so far provided little evidence for a direct link to the mainstream of rapid sensory information processing. But it is conceivable that some neuromodulatory neurons may form, remote from sensory input, a central system for integrating the activity states of many neural circuits. Thus, a release of neuromodulators may mediate the translation of the activity pattern of many neurons into the activity in biochemical pathways in single target cells.

A 330-metre core drilled through the marine Permian/Triassic boundary in the Carnic Alps of Austria allows closely correlated studies of geochemistry, petrography and palaeontology across the boundary. The isotope shifts and metal concentrations are extended, multiple and complex, and do not resemble those seen at the Cretaceous/Tertiary boundary. Both the carbon isotope shifts and the chemical events (including an iridium anomaly) may have causes related to a major regression of the sea.

THE Permian/Triassic (P/Tr) boundary is associated with the largest extinction event in Phanerozoic time[1]. It also witnessed important changes in the environment[2], notably indicated by a large drop in $\delta^{13}C$ of the surface ocean from the relatively enriched ^{13}C condition that characterized the late Palaeozoic[3,4]. A sudden decrease in $\delta^{13}C$ has also been observed in connection with other extinction events: the Precambrian/Cambrian[5], Ordovician/Silurian[6], Frasnian/Famennian[7], Devonian/Car-

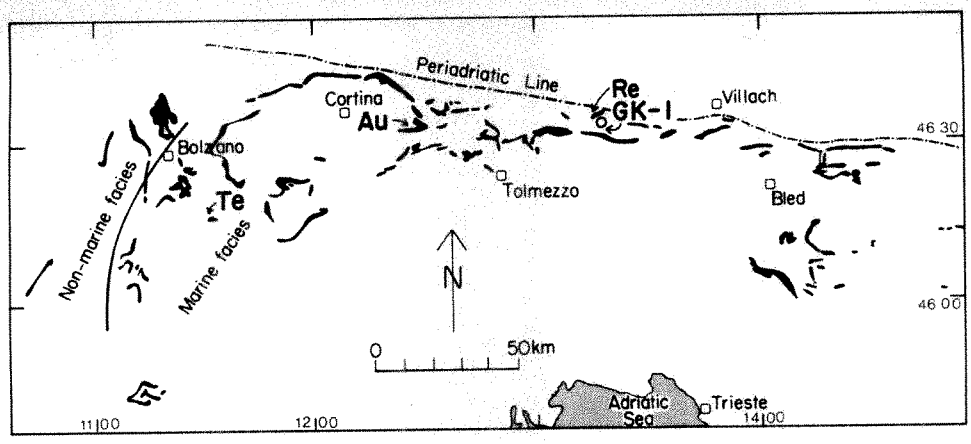

Fig. 1 Location of the Gartnerkofel-1 (GK-1) core hole in relation to the surface distribution of P/Tr rocks in the southern Alps[31]. Also shown are locations of the outcrop sections at the nearby Reppwand (Re), and at Tesero (Te) and Auronzo (Au), Italy[28]. The GK-1 locality is on a gently dipping marine shelf, 160 km east of the shoreline near Bolzano, Italy.

boniferous[8], Cenomanian/Turonian[9] and Cretaceous/Tertiary (K/T)[10]. At some of these boundaries, anomalous concentrations of metals, particularly iridium, have been observed. The high concentrations at the K/T boundary[11] and the more modest but distinct concentrations in the Late Eocene[12] have been widely ascribed to bolide impacts, whereas concentrations at some of the other extinction events[7,13-17], similar to those in the Late Eocene, may have been caused by terrestrial processes (biogenic, oceanic or volcanic).

Suggestions of iridium anomalies associated with the P/Tr boundary have been controversial. Notable iridium anomalies have been reported at exposures of the P/Tr boundary in China[16-19], but analyses of these same sections in other laboratories have failed to find iridium concentrations of more than 100 parts per 10^{12} (refs 20-23). Similarly low levels of iridium were found in P/Tr sections in Soviet Armenia[24] and in the Dolomite Alps[25,26].

Our objective in the current study has been to completely characterize the geochemistry and palaeoenvironment of a representative section of the P/Tr boundary, including carbon isotope and iridium characteristics as well as other measures, and to compare the conditions near the boundary with those in the contiguous sections of the Upper Permian and Lower Triassic.

The Gartnerkofel core

Previous studies of carbon isotope profiles of the P/Tr boundary have indicated that some of the most complete sections across the boundary were situated in the Southern Alps of Austria and Italy[27-29]. To obtain the best possible reference section free of any outcrop alteration, a continuous core was taken specifically for this purpose, on the north slope of the Gartnerkofel near Nassfeld in the Carnic Alps of Austria (Fig. 1). This locality was near the western end of the Tethys Sea, on a carbonate ramp gently inclined to the south-east and 160 km east of the shoreline exposed in the western Dolomite Alps[30,31]. Hole GK-1 started in the Muschelkalk Conglomerate (Upper Anisian), entered the Werfen Formation (Skythian) at 57 m, the Bellerophon Formation (Dzhufian–Dorashamian) at 231 m, and bottomed in the same formation at 331 m (Fig. 2). Oolites in the lowermost 6 m of the Werfen Formation correlate with the Tesero Horizon in the Italian Dolomites, where the P/Tr boundary, as defined by the last occurrence of Permian fusulinids[32-34], lies within this Tesero Horizon. In both GK-1 and the nearby outcrop on the Reppwand cliffs, conodonts were recovered from the lower 40 m of the Werfen Formation. The recognition of *Hindeodus parvus*, a conodont guide fossil for the Early Griesbachian[35,36], confirms a very thick and complete representation of lowermost Triassic sediments at this locality. The palaeomagnetic record in the core displays several polarity reversals, as seen in the Permo-Triassic Mixed (Illawarra) Superchron. The reversal nearest to the P/Tr boundary, from positive to negative polarity, lies within the Upper Permian (at 237.2 m); an analogous reversal in the P/Tr section at Shangsi, China, is close to the boundary within a sampling gap of 1.5 m (ref. 37).

The absolute time interval corresponding to the stratigraphic units outlined in Fig. 2 is difficult to assess. Units 1B to 3B—constituting a thickness of ~200 m—correspond to probably not more than one stage each of the Permian (Dorashamian) and Triassic (Griesbachian)[38], a time interval of ~5 Myr (ref. 39). This rate of ~40 m Myr^{-1} is equal to that calculated for the section at Shangsi[37], and is within the expected range for carbonate shelf sedimentation[40].

Closely coordinated sampling of the core allows comparison of a wide variety of data. About 300 billets were cut for thin-section preparation; the remainders of these billets were milled to powder and split for mineralogical, chemical and isotope analyses. Every one of the shaly or marly interbeds, about 50 in number and mostly a few millimetres thick, was similarly sampled and analysed. Samples were spaced in most of the core at a maximum distance of ~1 m, but were as close as 10 cm apart in the vicinity of the boundary. The complete scheme of sampling and analysis, and all the analytical results, are to be published elsewhere (W.T.H. *et al.*, to be submitted to *Jb. geol. Bund.*) Some salient features of the results are given here.

Carbon isotopes

The carbon isotope profile of Figs 2 and 3*a* suggests further subdivision of the section. Unit 1A, the middle part of the Bellerophon Formation (from the bottom of the core to 293.5 m), has ^{13}C-enriched values (mean $+3.0 \pm 0.3$‰). These values are within the range of those reported for Upper Permian rocks, both in other sections in the Alps[27,28] and throughout Tethys[29,41]. Unit 1B comprises the upper part of the Bellerophon Formation, where $\delta^{13}C$ values drop gradually from +2.8‰, to +1.5‰ at a depth of 231.3 m, at a rate of 0.02‰ m^{-1}. Comparison of this carbon isotope profile from GK-1 with others to the west at Tesero and Auronzo, Italy (Fig. 1)[28], indicates that this segment in GK-1 corresponds to the sharp drop in $\delta^{13}C$ that occurred within a few tens of centimetres in the Italy sections. In Unit 2 (the Tesero Horizon, which includes the P/Tr boundary) $\delta^{13}C$ continues to drop, reaching a value of 0.0‰ at 224.7 m. This segment has the same values of $\delta^{13}C$ and thickness as those of the Tesero Horizon at Tesero[28,42]. Unit 3A is an interval of low $\delta^{13}C$ in the lower part of the Mazzin Member of the Werfen Formation, extending to 175 m and including three minima, which will be discussed below. This multiple low was not found at any of the other P/Tr sections studied thus far. Units 3B and 4 comprise the upper part of the Werfen Formation, to 57 m, with a constant $\delta^{13}C$ of $+1.3 \pm 0.2$‰.

Oxygen isotopes

Values of $\delta^{18}O$ also show some consistent variations in certain intervals (Fig. 2). In Unit 1A the values of $\delta^{18}O$ show a bimodal distribution, centred at $\delta^{18}O = -0.5$ and -3.0‰, and the less

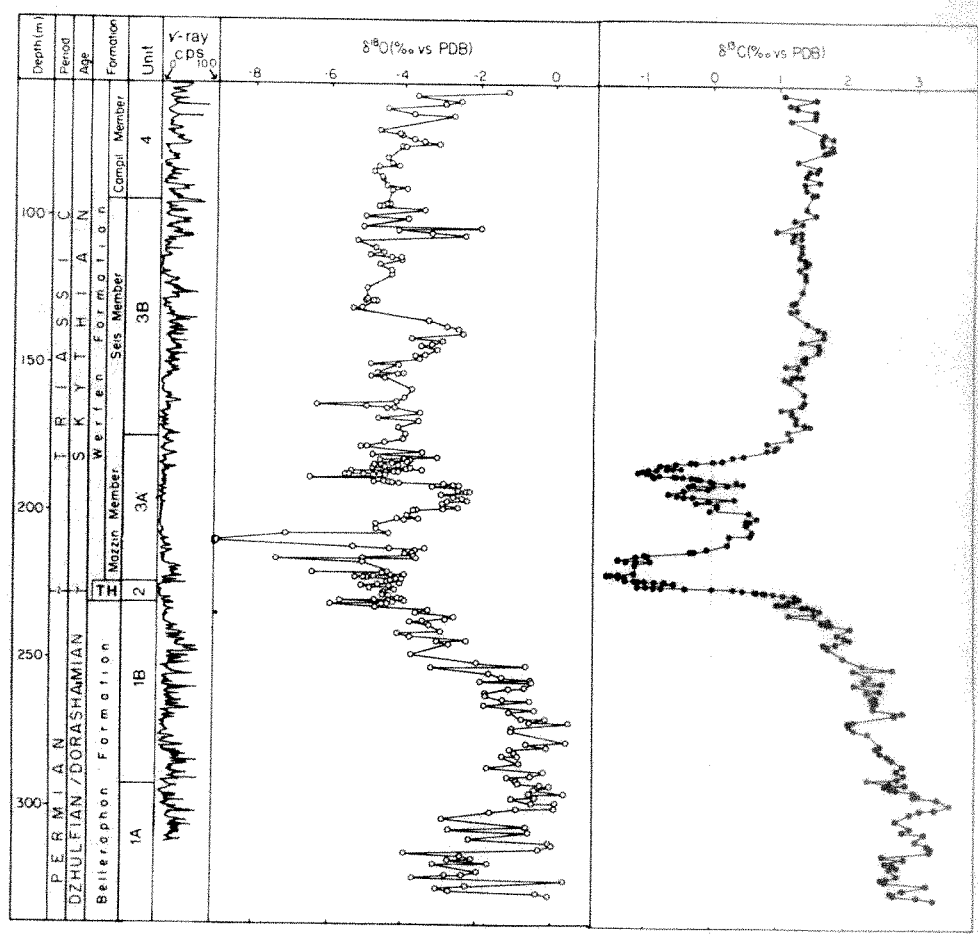

Fig. 2 Stratigraphy, geophysical log, and oxygen and carbon isotopes in GK-1. Four lithostratigraphic units are recognized, with subunits based on carbon isotope shifts. Virtually the entire section is fine-grained dolostone, with occasional millimetre-to centimetre interbeds of dolomitic marl or shale (natural γ-ray log >25 counts per second). Unit 1 is the middle and upper part of the Bellerophon Formation, a low-energy, homogeneous, bioturbated biomicrite of a shallow inner shelf, dominated by foraminifers. Unit 2 (231.0–224.5 m), the Tesero Horizon (TH), is transitional to a more shallow and restricted environment: oolites appear in the upper 4 m, with increasing tempestites, intraclasts, ostracodes and worm tubes. Unit 3 is the lower part of the Lower Triassic Werfen Formation, containing strongly bioturbated microsparite, with increasing coquina tempestites. In the interval 95–82 m the section becomes more red, less fossiliferous and richer in terrestrial clastics that characterize Unit 4. At the top of the section a hiatus of the higher parts of the Werfen Formation is followed at 75 m by the Anisian Muschelkalk Conglomerate (not shown). The clastic residues in Unit 1 are mainly illite/muscovite, whose measured crystallinity[67] attests to only very-low-grade diagenesis (<180 C). Upwards through Unit 3, detrital quartz and minor chlorite become dominant.

negative values continue in the lower part of Unit 1B. More negative $\delta^{18}O$ values of about −3.5‰ occur in the upper part of Unit 1B and persist consistently through Units 2 ($\delta^{18}O = -4.5 \pm 0.5$‰) and Units 3 and 4 ($\delta^{18}O = -4.2 \pm 0.8$‰), despite the substantial variations of $\delta^{13}C$ that characterize those intervals (Fig. 2). The consistent nature of the variations of $\delta^{18}O$ speaks for a mainly primary record of $\delta^{18}O$ in this core section. The depletion of $\delta^{18}O$ across the P/Tr boundary (Units 1 to 2 and 3) may be interpreted as indicative of a temperature rise of perhaps 5 °C.

Stable isotopes and chemistry across P/Tr

Detailed profiles of selected stable-isotope and chemical variations for the interval 235–175 m, which crosses the P/Tr boundary, are displayed in Fig. 3. This interval has complex variations of carbon isotopes and chemistry.

The smooth decrease of $\delta^{13}C$, which starts in Unit 1B, continues through Unit 2 at an accelerating rate, reaching 0.3‰ m^{-1}. This sharp drop in $\delta^{13}C$ signals the beginning of a zone of low $\delta^{13}C$ values, which includes three clear minima at 220 (−1.5‰), 193 (−0.6‰) and 186 m (−1.5‰), until a more stable regime with $\delta^{13}C \approx +1.3$‰ is re-established above 173 m (Fig. 2).

This ^{13}C-depleted zone is also characterized by chemical changes. The first and third carbon isotope minima have high concentrations of pyrite (>500 μmol g^{-1} S_2), as shown by dashed lines in Fig. 3*b*. Total Fe, shown as solid lines in Fig. 3*b*, is nearly matched (in μmol g^{-1}) by S_2 in these two pyritic intervals, underlain in both cases by oxidized intervals low in S_2, with most of the iron as goethite. Pyrite has wavy lamellar bedding consisting of globular masses 20–100 μm in diameter, similar to the early diagenetic 'framboidal' pyrite common in modern marine muds and in stratiform sulphide deposits such as the Kupferschiefer, Meggen and Rammelsberg[43,44]. Each of the stratigraphically distinct sulphide concentrations in Fig. 3*b* has a negative, uniform but distinct isotope ratio: for example, near 186 m, $\delta^{34}S = -19.3 \pm 0.2$‰ and at 221–222 m, $\delta^{34}S = -25.7 \pm 1.1$‰. These data indicate that the pyrite is syngenetic-diagenetic, and that each bed was deposited in its own distinct reducing environment. This conclusion is supported by rare-earth-element chemistry (Fig. 3*c*). Ratios of Ce^*/La^* have their highest values of ~1.0 in the intervals rich in pyrite, indicating anoxic conditions in the sedimentary regime[45,46]. Immediately below, in the interval 231–225 m, $Ce^*/La^* = 0.5 \pm 0.1$, as would be expected under the highly aereated conditions in which oolites are generated. The rise in Ce^*/La^* begins immediately above the oolite beds, 2 m below the beds in which considerable pyrite is preserved. Above the sulphide zone, Ce^*/La^* ratios (in shaly samples) decrease to intermediate values of ~0.7.

The iridium data also show two peaks (normalized to Al in Fig. 3*d*) that are substantially above background. The first (165 parts per 10^{12} Ir ($Ir/Al = 4.15 \times 10^{-9}$)), at the top of Unit 2 (224.5 m), occurs while $\delta^{13}C$ is still declining sharply towards its first minimum and the local conditions are just changing from oxic to anoxic. The second Ir peak (230 parts per 10^{12} ($Ir/Al = 6.80 \times 10^{-9}$)) is near the top of Unit 3A (185.6 m), centred on the third minimum of $\delta^{13}C$ and on a peak of S_2. The highest iridium concentrations are clearly above the relatively low background of iridium (10–30 ± 5 parts per 10^{12} in shaly samples) that apparently characterizes this geological period; they persist whether plotted as Ir/Al (Fig. 3*d*), Ir/Fe or just Ir. They are at least an order of magnitude lower than the iridium spike at the K/T boundary, but are similar to iridium concentrations described near other boundaries[7,13–15]. A log plot of Co against Ir (Fig. 4) shows that Permian/Triassic samples (including both our data from Austria and three analyses from China[21]) have lower Ir than (1) mean CI chondrite[47], (2)

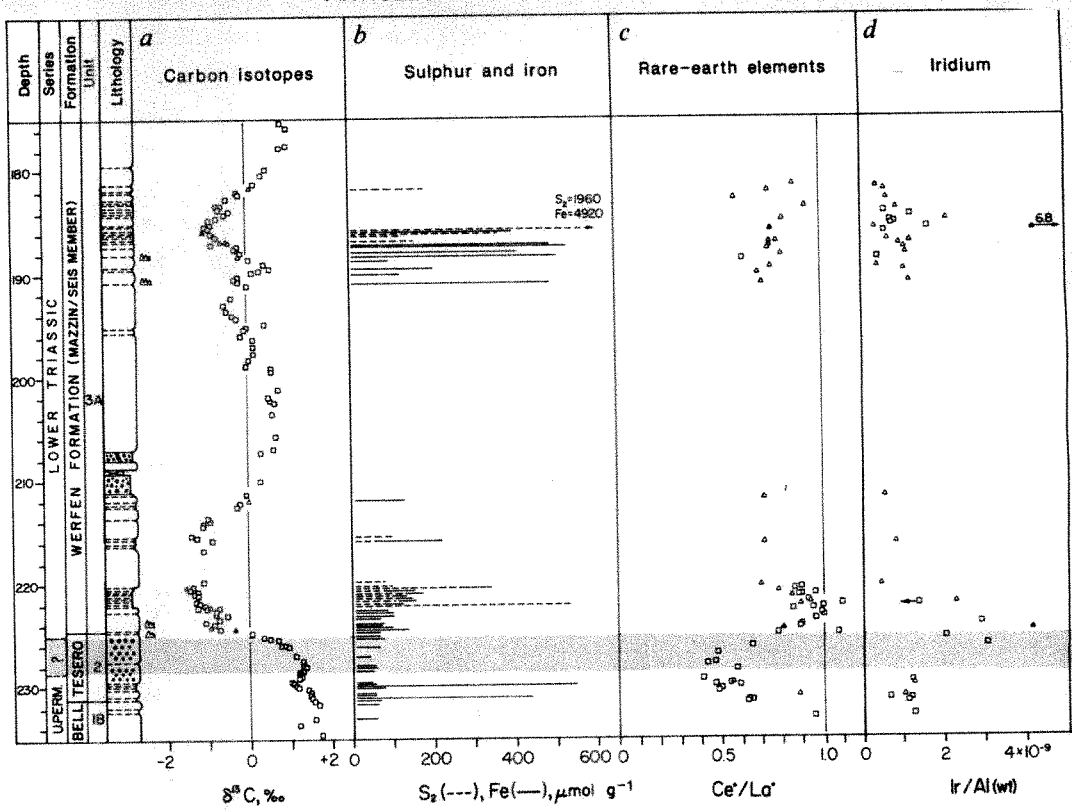

Fig. 3 Details of stratigraphy and geochemistry in GK-1, from 235 to 175 m, across the P/Tr boundary (shaded). Levels with *H. parvus* indicated alongside lithology. Squares represent dolostone, triangles represent shale or marl, and samples of the two iridium spikes are shown as solid symbols. *a*, Carbon isotope profile; note the steep but smooth decline of $\delta^{13}C$ across the P/Tr boundary, and the subsequent three minima in the lowermost Triassic; shale and carbonate samples are consonant. *b*, Total sulphur (nearly all is sulphide; analyses by combustion) and total iron (by instrumental neutron activation analysis (INAA)), expressed in $\mu mol\ g^{-1}$ of S_2 and Fe, respectively. In all cases the Fe is sufficient to indicate that all S appears as pyrite, FeS_2, which displays two peaks. *c*, Rare-earth elements (analysed by INAA), illustrated by Ce*/La*, each normalized to the North American shale composite[68]. Note the shift from low to high ratio (oxidizing to reducing conditions) at the upper boundary of the Tesero oolite. *d*, Iridium (analysed by RNAA), here normalized by its ratio to Al (analysed by INAA). The low background value of this ratio, at $\sim 1 \times 10^{-9}$, is maintained consistently through all the shaly layers and even above and below the section shown here. Two anomalies of many times the background level, at 4 and 7×10^{-9}, are seen at just above the P/Tr stratigraphic boundary as $\delta^{13}C$ passes through zero, and at about 40 m above the P/Tr boundary where $\delta^{13}C$ drops to its third minimum. Each of the two iridium anomalies rises sharply but drops off more slowly, over 1–2 m.

chondritic spherules from the deep sea[48], (3) chondritic spherules from the Tunguska event[49], and (4) peak spikes at the K/T boundary[50–51]. As indicated in Fig. 4, the ratios of Co/Ir in both background and in the nominal peaks of the GK-1 profile are more similar to those found in deep-sea muds[52] and manganese nodules[53,54]. Plots of Ni against Ir and Cr against Ir are similar to plots of Co against Ir.

Three samples from the upper Ir high were also analysed by radiometric neutron activation analysis (RNAA) for Au, and gave Au/Ir = 16, 30 and 56 (weight ratio). These are closer to the ratios found in basalts or kimberlites (summarized by Paul *et al.*[55]) than those in chondrites[47], K/T boundary clays[50] or deep-sea manganese nodules[53].

The weakest carbon isotope minimum (at 193 m; Fig. 3) is in a carbonate interval with no concentration of clay or pyrite, and has not yet been analysed for trace elements by NAA.

Geochemical measures of detrital provenance are constant, with no trend over the whole length of the core: $Th/Al = 0.161 \pm 0.028 \times 10^{-3}$ ($n = 76$) and $Ga/Sc = 1.70 \pm 0.36$ ($n = 25$). The latter ratio[56], and minor olivine and augite in heavy-mineral concentrates in Unit 3, suggest some input of fresh basic volcanic material, such as may have been derived from the Permian/Skythian Haselgebirge of the Northern Calcareous Alps[57].

Ten analyses of strontium isotope ratios ($^{87}Sr/^{86}Sr$) in carbonate rocks between 238 and 185 m (Units 1B, 2 and 3A), corrected for small amounts of radiogenic rubidium, had a mean value of 0.70742 (with a range of 0.70702–0.70777), similar to latest Permian[58] and earliest Triassic[2] rocks of western USA, but with no local evidence of an upward trend.

Modelling chemical changes

Taking into consideration the evidence presented here and that in earlier studies[2,3,28,29], we suggest the following model for changes that occurred in the environment across the P/Tr boundary.

The end of the Permian was characterized by one of the strongest regressions of the sea in the entire Phanerozoic[2], which explains why part of the boundary beds are missing in most of the marine sections around the world. Moreover, the thickness of the section in GK-1 that yields *H. parvus* (Fig. 3*a*) suggests that the Nassfeld area has a rather complete representation of 'boundary beds'. Thus the chemistry of GK-1 provides a very detailed record which substantially constrains the geochemical model.

A major shift in the carbon cycle was initiated early in the Dorashamian stage, based on evidence in sections across Tethys[29]. Thus the drop in $\delta^{13}C$ that begins in GK-1 (at least 50 m below the P/Tr boundary) indicates a net oxidation of the world reservoirs of organic carbon, as sea level dropped, exposing paralic and shallow shelves to erosion. The $\delta^{13}C$ profile in GK-1 confirms an acceleration in the rate of organic carbon oxidation as the boundary is approached, as was seen previously at Tesero, Italy[28]. At both Tesero[42] and in GK-1 (Fig. 3) the occurrence of oolites suggests that the sea had withdrawn to nearly expose these parts of the Tethys shelf.

A sharp change to anoxic conditions is evident at the top of Unit 2 in the GK-1 core by the rise in Ce*/La* and then the appearance of pyrite and high S/C ratios. The inception of anoxia, as $\delta^{13}C$ was dropping through zero for the first time, was marked by anomalous concentrations of iridium and other metals, and the maximum of the anoxic zone corresponds to the initial minimum in the profile of $\delta^{13}C$. A similar sequence is repeated during a later minimum of $\delta^{13}C$ at the top of Unit 3A (185.6 m), which is accompanied by another high concentration of metals and sulphide.

A (single) minimum zone of $\delta^{13}C$ at the base of the Early

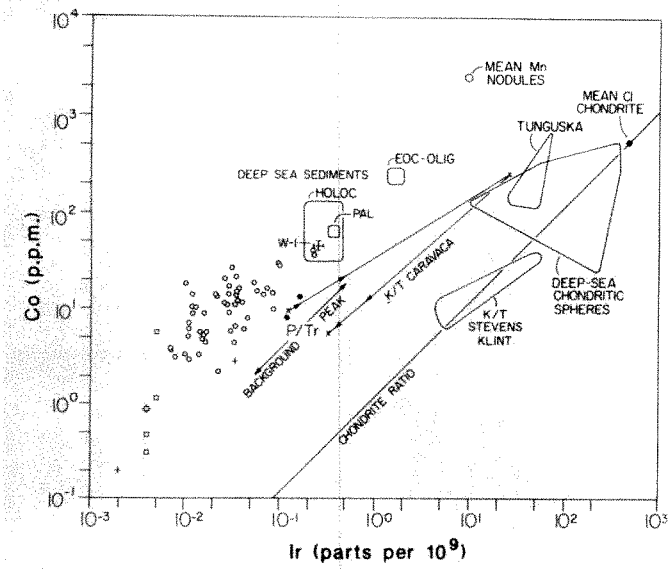

Fig. 4 Plot of cobalt against iridium on a log-log plot. Data from this study (from the Carnic Alps) are indicated as squares (dolostone) or circles (shale or marl); symbols for the two iridium spikes are solid. The data show a general positive correlation, but at a relatively lower Ir value than that for mean CI chondrite[47] or chondritic spherules[48,49]. Shown for comparison are two values for the P/Tr boundary beds in Changxing, China[21] (+), and two examples of the K/T peak (transition through the spike at Caravaca, Spain[50], marked ×, and the range of peak values at Stevens Klint, Denmark[51]). Also shown are approximate ranges of background for Palaeocene and Eocene-Oligocene (ref. 69 and F. T. Kyte and K. T. Wasson, personal communication) and Holocene (Ir: ref. 52; Co: ref. 70) deep-sea sediments, and mean values for manganese nodules (Ir: ref. 53; Co: ref. 54).

Triassic has been verified on a global scale[3,29]. The chemical changes that we see in GK-1—high iridium, other metals, sulphide and cerium—are certainly an important local signal, although they have not yet been found elsewhere. Whether they are local or worldwide, one must ask why these chemical changes have followed so closely upon the primary, worldwide, longer-term shifts of the carbon cycle. The explanation may be that both the carbon isotope shift and the chemical changes were caused by the same regression of sea level, which first exposed organic carbon to oxidation and finally brought about anoxic conditions to precipitate metals in at least this part of the Tethys Sea. This is consistent with increased erosion of upraised red beds[59] and volcanics[60], now exposed west of Bolzano (Fig. 1), bringing metals into solution which were finally reprecipitated on contacting the anoxic waters that had been generated in Tethys. Alternatively, the metals may have been dissolved from the red beds of the underlying Gröden Formation, and precipitated at the oxidation/reduction interface, as has been proposed for the metal-rich (including platinum-group elements) shales of the Kupferschiefer[61–63].

Accumulation of metals may have been aided by algae, whose presence is suggested by the lamellar textures seen in this interval. If detailed investigations of other sections show that anoxia and concentrations of metals are localized in this Bellerophon basin, one might then suggest that the cause is an estuarine-style topflow of the fresh waters from the lands to the west during the maximum regression of the Tethys Sea. Alternatively, on a larger scale it could represent a final phase of a deep-sea oxygen-minimum zone that was prevalent for much of the Palaeozoic[64,65], brought near the surface during this maximum regression. The prevailing incidence of fresh water eroding continental rocks during this period of regression is evidenced by the high values of $^{87}Sr/^{86}Sr$ compared with those of earlier Permian time[2], but we have not seen a short-term positive spike such as that seen at the K/T boundary[66].

Unlike other boundaries, for which a single rather sharp drop in $\delta^{13}C$ is followed by a relatively rapid recovery to normal $\delta^{13}C$, we found in GK-1 a thick section (Unit 3A, about 50 m) of low $\delta^{13}C$, including three separate minima, the two largest of which were characterized by anoxic conditions and enrichment of metals including iridium. Isotope profiles presented previously[28,29] have indicated that important worldwide changes in the carbon cycle had already begun in Late Permian time and continued smoothly across the stratigraphic P/Tr boundary to culminate in the Early Triassic. The detailed study of GK-1 confirms this extended interval of change, and presents a complex picture of oxidation, reduction and metal deposition constrained within the interval of carbon variations. The evidence presented here, from the most dramatic of all mass extinction events, provides a scenario that is completely different from the bolide impact model proposed for the K/T event, and which is less dependent on iridium anomalies. Certainly, a sharp event or events such as are seen at the K/T boundary are not in evidence here.

The geological coring was funded by the Fonds zur Förderung der Wissenschaftlichen Forschung and the NSF under the Austria-USA Cooperative Science Program. Some of the analytical work was supported by the Geologische Bundesanstalt, NASA and the US Department of Energy, and The Weizmann Institute.

GroE heat-shock proteins promote assembly of foreign prokaryotic ribulose bisphosphate carboxylase oligomers in *Escherichia coli*

Pierre Goloubinoff, Anthony A. Gatenby* & George H. Lorimer

Central Research and Development Department, Experimental Station, E.I. DuPont de Nemours and Co., Wilmington, Delaware 19880-0402, USA

Assembly of foreign prokaryotic ribulose bisphosphate carboxylases (Rubiscos) in Escherichia coli *requires both heat-shock proteins groEL and groES. GroEL is related to a chloroplast protein implicated in Rubisco assembly. Bacteria and chloroplasts therefore have a conserved mechanism that uses auxiliary proteins to assist in the assembly of Rubisco.*

THE subunits of some oligomeric proteins lack the inherent ability to correctly assemble into biologically functional molecules[1–4]. For the post-translational assembly of these polypeptides into oligomeric structures a ubiquitous class of conserved proteins, termed 'chaperonins', is thought to be involved[1]. This class of proteins includes the *E. coli groEL* gene product[1], as well as homologous proteins in other bacteria[5,6], chloroplasts[1], and mitochondria from plants, fungi and animals[7].

Both groEL and groES proteins are necessary for the morphogenesis of certain bacteriophages[8–12]. They are also involved in DNA replication in *E. coli*[13,14]. A molecular mechanism accounting for the involvement of the groE proteins in these processes is lacking however. The chloroplast homologue of groEL is called the Rubisco-binding protein because of its demonstrated association with newly synthesized chloroplast-encoded Rubisco large subunits[15,16], or with subunits imported into the organelle[17]. Both GroEL and Rubisco-binding protein have a similar structure and share extensive amino-acid sequence homology[1,18]. It has been suggested that in chloroplasts the Rubisco-binding protein is involved in assembly of hexadecameric (L_8S_8) Rubisco[19–21]. Here again, a detailed molecular mechanism is wanting.

Chloroplast Rubisco is comprised of eight large subunits and eight small subunits[22]. Rubiscos with a similar structure are present in most photosynthetic prokaryotes[23]. However, another form of Rubisco, a dimer (L_2) of large subunits, exists in the prokaryote *Rhodospirillum rubrum*[24]. The dimer from *R. rubrum* is similar in structure to a pair of large subunits of chloroplast Rubisco[25–27]. The structure of the hexadecameric chloroplast enzyme can be generated by tetramerization of *R. rubrum*-like dimers, to which the eight small subunits are polarily appended[26–28]. Both the prokaryotic L_2 and L_8S_8 enzymes can be synthesized and assembled in *E. coli*[29–32]. The demonstrated homology between the *E. coli* groEL protein and the chloroplast Rubisco-binding protein[1], led us to consider the possibility that the assembly of prokaryotic Rubisco in *E. coli* involves the bacterial groEL protein.

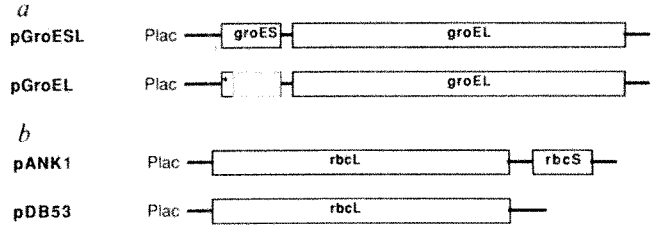

Fig. 1 Plasmid constructions. Two series of compatible plasmids were co-transformed in *E. coli* hosts. *a*, The first series (pGroESL and pGroEL) used plasmid pTG10, which has a p15A replicon, as a parent vector for the *groE* genes. pGroESL contains the *E. coli groES* and the *groEL* genes cloned in pTG10. pGroEL contains a frame-shifted (inactivated) *groES* gene followed by a wild-type *groEL* gene cloned in pTG10. *Translation frameshift. *b*, The second series of plasmids (pANK1 and pDB53) used pUC18 and pUC8 plasmids respectively, as parent vectors for the Rubisco genes. The pUC plasmids have a pMB1 replicon which is compatible with the p15A replicon. pANK1 (ref. 37) codes for both the Rubisco *rbcL* and *rbcS* genes from *A. nidulans*. cloned in pUC18 (ref. 38). pDB53 (ref. 31) codes for only the *A. nidulans rbcL* gene, cloned in pUC8 (ref. 39).
Methods. Plasmid pTG10 was derived from plasmid pACYC184 (ref. 40) which was cut with *Hin*dIII/*Bam*HI and repaired with Klenow. Into this repaired site was inserted a S1-nuclease-treated 433 base-pair *Hae*II fragment, containing the *lac* promoter and the multiple cloning site from plasmid pUC8. Plasmid pGroESL was made by cloning the *groE* operon, as a 2.3 kb *Eco*RI–*Hin*dIII fragment from plasmid pOF39 (ref. 13), into pTG10. Plasmid pGroEL was derived from a partial *Sac*II digestion of pGroESL, treated with T4 DNA polymerase. The resulting repair of the *Sac*II site located at codon 37 of *groES*[13] produced a frame-shift mutation.

Here, we show that assembly of prokaryotic dimeric (L_2), octomeric (L_8), and hexadecameric (L_8S_8) Rubiscos in *E. coli* requires both groES and groEL proteins. Although the groE proteins have been shown to mediate the assembly of L dimers from monomers, we cannot exclude subsequent involvement of these proteins in the formation of octomers and hexadecamers from these dimers.

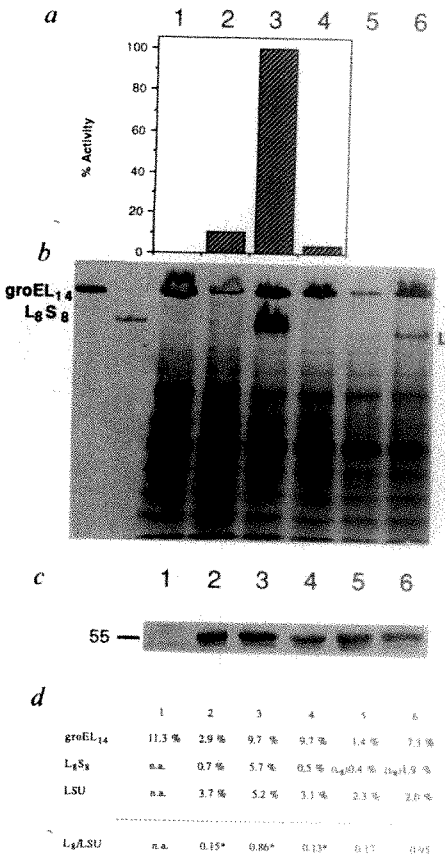

Fig. 2 *In vivo* assembly of Rubisco in *E. coli*. A *recA*56 isolate of strain MC1061 (ref. 41) was co-transformed with the following plasmids: (1) pUC18 and pGroESL; (2) pANK1 and pTG10; (3) pANK1 and pGroESL; (4) pANK1 and pGroEL; (5) pDB53 and pTG10; (6) pDB53 and pGroESL. *a*, Rubisco activity in the cell lysates. *b*, Non-denaturing 7% polyacrylamide gel electrophoresis of lysate proteins, strained with Coomassie Blue. Purified groEL[42] and spinach L_8S_8 Rubisco[43] are shown on the two left lanes. *c*, SDS-polyacrylamide gel electrophoresis of cell lysates, revealed by immunodetection with an antiserum raised against *A. nidulans* Rubisco large subunit. The large subunit appears as a band of relative molecular mass (M_r) 55,000. *d*, [^{35}S] counts incorporated in protein complexes from native and SDS-polyacrylamide gels as in *b* and *c*, respectively as a percentage of total TCA counts. n.a, not available; *, predicted L_8 values from L_8S_8 values; LSU, large subunit.

Methods. Cells grown on 2YT medium (16 g Bacto-Tryptone, 10 g Difco yeast extract, 5 g NaCl per litre) under selective conditions, were harvested at $A_{600} = 0.4$ and resuspended in 100 mM Bicine (*p*H 8.0), 10 mM $MgCl_2$, 30 mM $NaHCO_3$, 15% glycerol, 1 mM dithiothreitol, 15 mg ml^{-1} phenylmethyl-sulphonyl fluoride, 0.5 mg per ml lysozyme, 0.5 mg per ml deoxyribonuclease, 0.1 mg per ml ribonuclease. Samples were sonicated twice and centrifuged at 6,000 r.p.m. for 1 min at 4 °C. The protein concentration in the supernatant was measured using a Bio-Rad protein assay and adjusted to 5 mg protein per ml. The Rubisco activity was measured as the formation of acid-stable ^{14}C during a 20-min assay at 25 °C, using 100 μg of protein extract in 0.2 ml of 100 mM Bicine-NaOH (*p*H 8.0), 10 mM $MgCl_2$, 1 mM dithiothreitol, 0.4 mM ribulose 1, 5-bisphosphate and 30 mM [^{14}C]$NaHCO_3$. (In the presence of both the pGroESL and pANK1 plasmids *E. coli* produced 0.26 nmol of active sites per mg protein as measured by [^{14}C]CABP binding[44]. 100% activity represents 8.0 nmol of CO_2 fixed per mg protein per min. This corresponds to a turnover number of about 0.5 s^{-1} and suggests that the enzyme may not have a full complement of small subunits). Non-specific $^{14}CO_2$ fixation was measured in the presence of 100 μM carboxy arabinitol bisphosphate, a specific inhibitor of Rubisco[33]. The results were corrected for this background fixation. In a separate experiment, cells were grown for 90 min in 2YT medium supplemented by 100 μCi ml^{-1} of [^{35}S] methionine, collected and lysed as above. Samples were analysed by non-denaturing PAGE on 7% gels and to SDS-PAGE on 15% gels. Bands containing the native groEL and Rubisco proteins were excised from the non-denaturing gel whereas the band containing the Rubisco large subunit was excised from the SDS gel. Counts of individual gel bands were normalized with values obtained for total cell lysates using precipitation in 10% cold trichloracetic acid.

GroE proteins stimulate Rubisco assembly

To demonstrate that groE proteins are involved in the assembly of Rubisco in *E. coli*, the level of cellular groE proteins was increased by cloning the *groE* genes on a multicopy plasmid. Two sets of compatible plasmids were constructed. The *E. coli groE* genes were cloned on a chloramphenicol resistant plasmid containing a p15A replicon (Fig. 1*a*), and the *Anacystis nidulans* Rubisco genes (*rbc*) were cloned on an ampicillin-resistant plasmid containing a pMB1 replicon (Fig. 1*b*). The presence of the plasmid encoding *groES* and *groEL* (pGroESL) in *E. coli* increased the amount of groEL protein from its usual level of 1–2% of cell protein, to about 10% (Fig. 2, *b*, *d*).

E. coli cells containing the plasmid encoding the *A. nidulans rbcL* and *rbcS* genes (pANK1) produced active Rubisco enzyme that accumulated to a level of 0.7% of cell protein during logarithmic growth (Fig. 2, sample 2). By increasing the cellular concentration of groE proteins with plasmid pGroESL, a substantial increase in Rubisco activity was observed (Fig. 2*a*, sample 3). This activity was inhibited (>98%) by the addition of carboxy-D-arabinitol 1,5-bisphosphate (CABP), a specific inhibitor of Rubisco[33]. An increased quantity of holoenzyme was also apparent on non-denaturing gels (Fig. 2*b*, sample 3). The identity of the gel band was confirmed by immunoblotting, and was found to correspond to 5.7% of the cell protein, as judged by the incorporation of [^{35}S] methionine (Fig. 2*d*, sample 3). Except for the groEL and Rubisco oligomers, the pattern of other proteins in Fig. 2*b* remained similar. Despite the 10-fold variation in active assembled holoenzyme, immunoblotting of SDS-polyacrylamide gels revealed that each of the cell lysates contained comparable quantities of Rubisco large subunit polypeptides (Fig. 2*c*, samples 2 and 3). The incorporation of [^{35}S]methionine into large subunits did not vary by more than a factor of ~2.5 (Fig. 2*d*). Therefore, the increased amount of assembled and active Rubisco arising from overproducing the groE proteins could not be attributed to increased expression of the Rubisco genes, or increased protein stability. We conclude that groE proteins are involved in the post-translational assembly of nascent Rubisco polypeptides into a functional holoenzyme.

On structural grounds, we believe that the final step in assembly of hexadecameric Rubisco is the addition of small subunits to a preformed L_8 octomer, and that small subunits are not involved in the assembly of this octomeric core. Evidence for this is provided by the observations that *A. nidulans* L_8 cores are produced in *E. coli* in the absence of small subunits[31], and that small subunits can be added to pre-formed cores to yield an active enzyme[34]. To examine the influence of groE proteins on the assembly of the L_8 cores alone, a plasmid (pDB53) was used which encodes the large subunit of *A. nidulans* Rubisco (Fig. 1*b*). When large subunit synthesis was directed by plasmid pDB53 in a strain with wild-type levels of groE proteins, a small amount of Rubisco L_8 cores were observed (Fig. 2*b*, sample 5). In a strain overproducing the groE proteins a significant increase in assembled L_8 cores was observed (Fig. 2*b*, sample 6). The limited activity of the L_8 cores in the absence of small subunits precluded measurements of enzymic activity in unfractionated lysates. However, titration with [^{14}C]CABP revealed that 0.14 nmol of sites were formed per mg of cell protein. Using the criteria described earlier, similar levels of Rubisco large subunit polypeptides were found between the various SDS-solubilized cell lysates (Fig. 2*c*, samples 5 and 6), which thus excluded the influence of the groE proteins on the expression or stability of the large subunit. Therefore, the groE proteins are involved in the conversion of nascent polypetides into L_8 cores.

Mutations in *groE* prevent Rubisco assembly

If groE proteins promote Rubisco assembly, then mutations in the *groE* locus should confirm the role of the groE proteins,

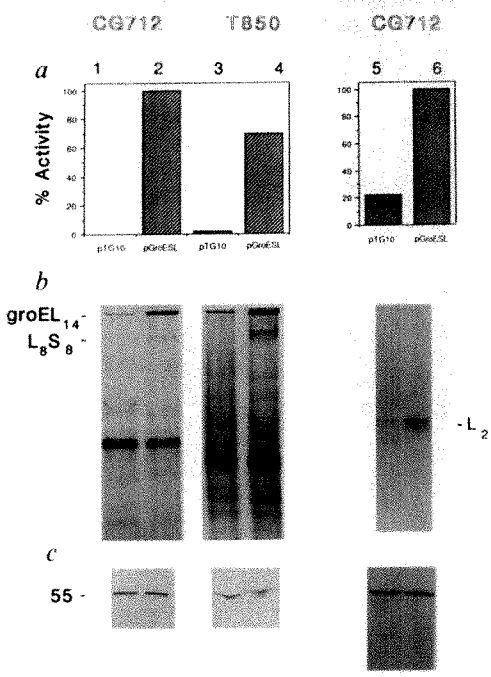

Fig. 3 Suppression by complementation of a deficiency in Rubisco assembly in strains of *E. coli* harbouring defects in the chromosomal *groE* operon. *E. coli groES*$^-$ mutant CG712 (ref. 13) or *groEL*$^-$ mutant T850 (ref. 45), harbouring *A. nidulans rbcL* and *rbcS* genes on plasmids pANK1 (samples 1–4) were co-transformed with the control pTG10 (samples 1 and 3) or with pGroESL (samples 2 and 4). The *groES*$^-$ mutant (CG712) was co-transformed with pRR2119 (fef. 29), which contains the *R. rubrum rbcL* gene, and with either the control plasmid pTG10 (sample 5) or with the pGroESL plasmid (sample 6). *a*, Rubisco activity in cell lysates, *A. nidulans*, samples 1–4; *R. rubrum*, samples 5, 6. 100% activity corresponds for *A. nidulans* Rubisco to 4 nmol CO_2 fixed per mg protein per min, and for *R. rubrum* Rubisco to 10 nmol CO_2 per mg per min. *b*, Non-denaturing PAGE (7% gels) of *E. coli* proteins, stained with Coomassie Blue (lanes 1–4) or revealed by immunodetection (lanes 5,6); *c*, SDS-PAGE (15% gels) of cell lysates, revealed by immunodetection with an antiserum raised against *A. nidulans* Rubisco large subunit M_r 55,000 (lanes 1–4) or against the *R. rubrum* enzyme (lanes 5, 6). The methods for preparing and analysing cell lysates are given in the Fig. 2 legend.

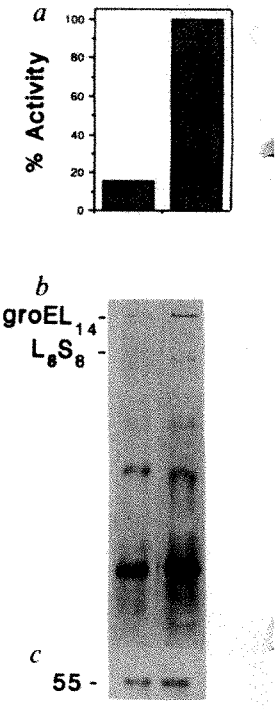

Fig. 4 Thermo-induction of Rubisco assembly. Wild-type *E. coli* cells (MC1061), harbouring plasmid pANK1, were grown either at 26 °C (left lane) or at 42 °C (right lane) to the cell density of A_{600} 0.4 from a common inoculum, initially grown at 26 °C, *a*, Rubisco activity in cell lysates (100% corresponds to 2.5 nmol of CO_2 fixed per mg protein per min) *b*, Non-denaturing PAGE (7% gel) of cell lysates stained with Coomassie Blue) *c*, SDS-PAGE of cell lysates in 1% SDS, 1% β-mercaptoethanol, revealed by immunodetection with an antiserum raised against *A. nidulans* Rubisco large subunit (M_r, 55,000). The methods for preparing and analysing the cell lysates are given in the Fig. 2 legend.

and perhaps identify the relative importance of groES and groEL in the process. Rubisco assembly was examined in *E. coli* strains with mutations in *groES* (strain CG712) or *groEL* (strain T850), or by using a groE overproducing plasmid (pGroEL) which had a frameshift mutation introduced into the *groES* gene (Fig. 1*a*).

When the *A. nidulans* Rubisco expression plasmid (pANK1) was transformed into CG712 (*groES*$^-$), neither Rubisco activity (Fig. 3*a*, sample 1) nor assembled holoenzyme (Fig. 3*b*, sample 1) could be detected. The compatible groES and groEL overproducing plasmid (pGroESL) was introduced into this strain to complement the mutation, which then allowed a significant production of active Rubisco holoenzyme from plasmid pANK1 (Fig. 3*a*, *b*, sample 2). A similar result was obtained using the *groEL*$^-$ strain T850. Virtually no Rubisco activity (Fig. 3*a*, sample 3) or assembled holoenzyme (Fig. 3*b*, sample 3) could be detected when T850 was transformed with the Rubisco expression plasmid (pANK1). When the groEL mutation of T850 was complemented by the presence of plasmid pGroESL however, both Rubisco activity (Fig. 3*a*, sample 4) and assembled holoenzyme (Fig. 3*b*, sample 4) were observed.

The influence of groES on Rubisco assembly was also demonstrated using the dual plasmid expression system. Figure 2 shows that an increased production of the groE proteins encoded by pGroESL led to improved assembly of hexadecameric (samples 2 and 3) and octomeric (samples 5 and 6) Rubisco. The *groES* gene of plasmid pGroESL was inactivated by introducing a translational frame-shift to produce plasmid pGroEL (Fig. 1). The presence of the *groES* frame-shift plasmid (pGroEL) and the Rubisco expression plasmid (pANK1) together in *E. coli* did not lead to improved assembly of Rubisco (Fig. 2, sample 4), thus emphasizing the involvement of groES in assembly of the hexadecameric enzyme. The *groES* frame-shift did not have a significant polar effect on expression of *groEL* because the plasmid-encoded *groEL* oligomer was present as an abundant protein (Fig. 2*b*, *d*, sample 4). Also, synthesis and stability of the Rubisco large subunit were unaffected (Fig. 2*c*, *d*, sample 4).

Recent structural studies of the L_8S_8 holoenzyme have revealed that the L_8 core is composed of four *R. rubrum*-like dimers arranged about a fourfold axis, the L_2 dimer being the basic structural and catalytically functional motif (see Fig. 5)[25–28]. This suggested that assembly of L dimers might be an essential intermediary stage in the formation of the L_8 core, and so the role of the groE proteins in this step was examined. The *groES*$^-$ *E. coli* mutant (CG712) was transformed with a plasmid (pRR2119) which codes for the *R. rubrum* Rubisco gene. Active, dimeric Rubisco could be detected in extracts from this strain (Fig. 3*a*, *b*, sample 5). However, the amount of active dimeric Rubisco was increased almost fivefold when the *groE* expression plasmid (pGroESL) was introduced into the *groES*$^-$ strain containing the *R. rubrum* Rubisco plasmid pRR2119 (Fig. 3*a*, *b*, sample 6). Again, the level of Rubisco subunits synthesized remained constant despite the different amounts of groE proteins produced (Fig. 3*c*, samples 5 and 6). The groE proteins are required for cell viability at 37 °C[1], and the mutant forms of groES and groEL present in CG712 and T850 would be expected to retain some residual or altered function. This may explain the presence of low levels of active Rubisco detected in *groE*$^-$ mutants (Fig. 3*a*, samples 3 and 5). The enhanced assembly of the L_2 dimer, observed by complementation and overexpression of *groES* and *groEL*, indicated that these proteins functioned at the very least at the stage of dimer formation.

Heat shock improves Rubisco assembly

In *E. coli* the expression of *groES* and *groEL* is stimulated following heat shock[35]. As assembly of Rubisco is influenced by the *groE* proteins, a heat shock to cells synthesizing Rubisco subunits might result in increased assembly of holoenzyme.

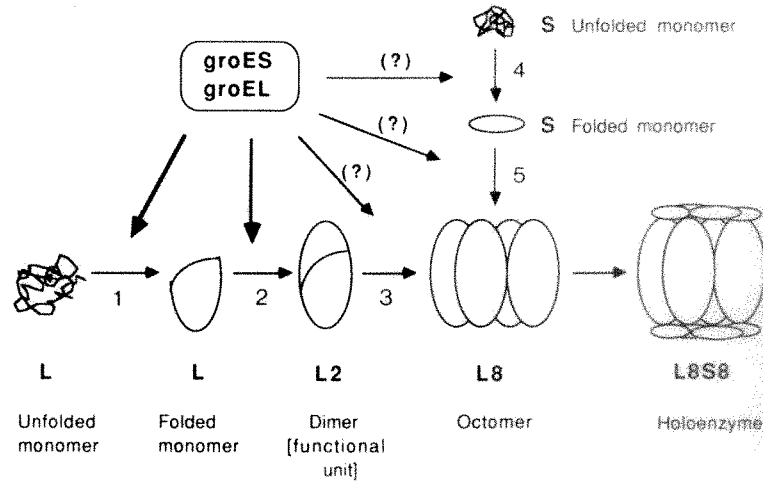

Fig. 5 Proposed assembly pathway of Rubisco hexadecamer. Recognizing that the L_2 dimer is the basic structural motif[25], a minimum of five steps must be invoked to convert nascent, unfolded large and small subunits into the hexadecameric L_8S_8 holoenzyme: (1) folding of large subunit monomer; (2) formation of the L_2 dimer; (3) tetramerization of L_2 dimers to give the L_8 core; (4) folding of small subunit monomer and (5) association of small subunits with the L_8 core. The groE proteins could potentially be involved at each step, although evidence[36] suggests that step 5 can occur spontaneously without their involvement. The results reported here show that, at the very least, the groE proteins are involved in dimer formation (that is, steps 1 and/or 2). However, the possibility that the groE proteins are additionally involved in steps 3 and 4 cannot be excluded.

A strain (MC1061) with wild-type chromosomal *groES* and *groEL* genes was transformed with the plasmid encoding *A. nidulans* Rubisco genes (pANK1). Cells were grown at 26 °C in liquid culture, and then inoculated into fresh media at either 26 °C or 42 °C. The heat shock increased the synthesis of groEL (Fig. 4*b*), and also resulted in a sixfold increase in Rubisco specific activity (Fig. 4*a*). Production of the L_8S_8 holoenzyme was also enhanced (Fig. 4*b*), but there were comparable amounts of large subunits produced at both temperatures (Fig. 4c). When the experiment was repeated with a *groEL*$^-$ strain (T850), only background levels of assembled enzyme were obtained (data not shown). The stimulation of Rubisco assembly by heat shock therefore required a functional groEL protein. The pleiotropic nature of the heat-shock response requires some caution in interpretation of these experiments. The results are consistent however with the *groE* overproduction experiments and use of mutants described earlier.

Discussion

The experiments described here demonstrate that the groES and groEL proteins are both obligate accessories for the assembly of prokaryotic Rubiscos in *E. coli*. The assembly of dimeric, octomeric and hexadecameric Rubiscos are all influenced by the groE heat-shock proteins. There are several potential sites of action for groE proteins in the assembly of Rubisco (Fig. 5). These sites of action might be non-exclusive and could be at the steps of polypeptide-chain folding to form L and S monomers, dimerization of L monomers, tetramerization of L dimers, or adjunction of small subunits to the L octomer. Experimentally, we have shown that the groE proteins are required for assembly of the *R. rubrum* L dimer. Dimerization of L could be the basic common step involved in the assembly of the L octomer and the L_8S_8 hexadecamer of *A. nidulans*. Addition of small subunits to the L_8 core does not seem to require groE proteins, as this step can be accomplished *in vitro* with no additional protein factors[36]. We cannot exclude a role for the groE proteins in the folding of the small subunits.

Our data shows for Rubisco, and implies for other proteins, that the primary structure of some oligomeric proteins is insufficient to specify their spontaneous assembly into a biologically active form *in vivo*. The dependence of a foreign oligomeric protein on host heat-shock proteins for correct assembly provides experimental evidence for the existence of a conserved mechanism capable of controlling the assembly of a variety of oligomeric proteins. This has also been inferred by structural comparisons of chaperonins[1].

The requirement for groES in Rubisco assembly in *E. coli* is of particular interest when considering the biogenesis of organelles in eukaryotes. A groEL homologue is present in chloroplasts and mitochondria[1,7], and has been implicated in the assembly of plant Rubisco[19–21]. The sequence and functional conservation of groEL in protein assembly leads us to predict that a protein with a function analogous to groES may be present in organelles to assist the post-translational assembly of some of their proteins.

A second supernova inside Puppis A?

P. F. Winkler*, R. P. Kirshner†, J. P. Hughes† & S. R. Heathcote‡

Young supernova remnants provide rare glimpses of material from the cores of massive stars, leading to observational tests of stellar evolution and nucleosynthesis theories. Here we present narrow-band images of an unusual swirl structure located near the centre of the Puppis A supernova remnant, which reveal three overlapping filamentary systems of highly diverse composition. One is dominated by emission lines of nitrogen, one by oxygen and one by sulphur. Spectra indicate that these small rings have high velocities and a corresponding kinematic age of less than 800 yr. Heavy-element abundances are extremely high and different in each system, some reminiscent of knots in Cas A, and others of circumstellar matter observed surrounding supernova 1987A. The youth and unusual chemistry lead us to suggest that a second supernova has exploded within the shell of Puppis A, giving rise to the swirl structure. A similar suggestion was made by Elliot *et al.*[1], based only on the region's appearance in Hα.

The irregular shell structure of Puppis A, about 50 arcmin in diameter, is apparent at both radio[2] and X-ray[3] wavelengths. Its bright optical filaments lie predominantly near the shell's rim to the north-west and to the east (Fig. 1). Spectra of these bright filaments show emission lines typical of supernova remnants (SNRs), although some are notable for very strong nitrogen lines[4-6]. Measured radial velocities[7,8] for these filaments have without exception been modest, $v_r < 300$ km s^{-1}. In striking contrast are a recently discovered[9] set of faint filaments which have strong oxygen lines, almost no Balmer emission, and radial velocities as high as 1,500 km s^{-1}. Proper motions for the latter filaments are consistent with undecelerated expansion from a common origin 3,700 years ago[10]. The explosion of a massive star ~4,000 years ago is consistent with all previous data from Puppis A at X-ray, optical and radio wavelengths.

Our new observations come from a complex region[1] which comprises filamentary systems of three different types, two of which have not been previously observed in Puppis A. This structure is centred near $\alpha = 8^h20^m56^s$, $\delta = -42°50'$ (1950), 3 arcmin south-east of the centre from which the fast oxygen-rich filaments are expanding[10], and appears as a swirl of emission ~4 arcmin in diameter—less than one tenth of that of Puppis A—on the deep Hα + [N II] plate shown in Fig. 1. No excess emission of the swirl region over its surroundings is seen in radio[2] or X-ray[3] maps of Puppis A.

We used the prime-focus CCD camera with an RCA chip at the CTIO 4-m telescope on 17 February 1988 to obtain narrow-band images of the swirl region at wavelengths of three prominent emission lines plus a continuum image (see Table 1 for details). The four images are shown in Fig. 2. Each of the emission-line images shows a filamentary structure typical of SNRs, yet the images in the different bands are so dissimilar that it would be difficult to recognize them as the same object, were it not for the star field.

Two nights later we used the Ritchey-Chretien spectrograph and 2D-Frutti detector on the CTIO 4-m telescope to obtain a

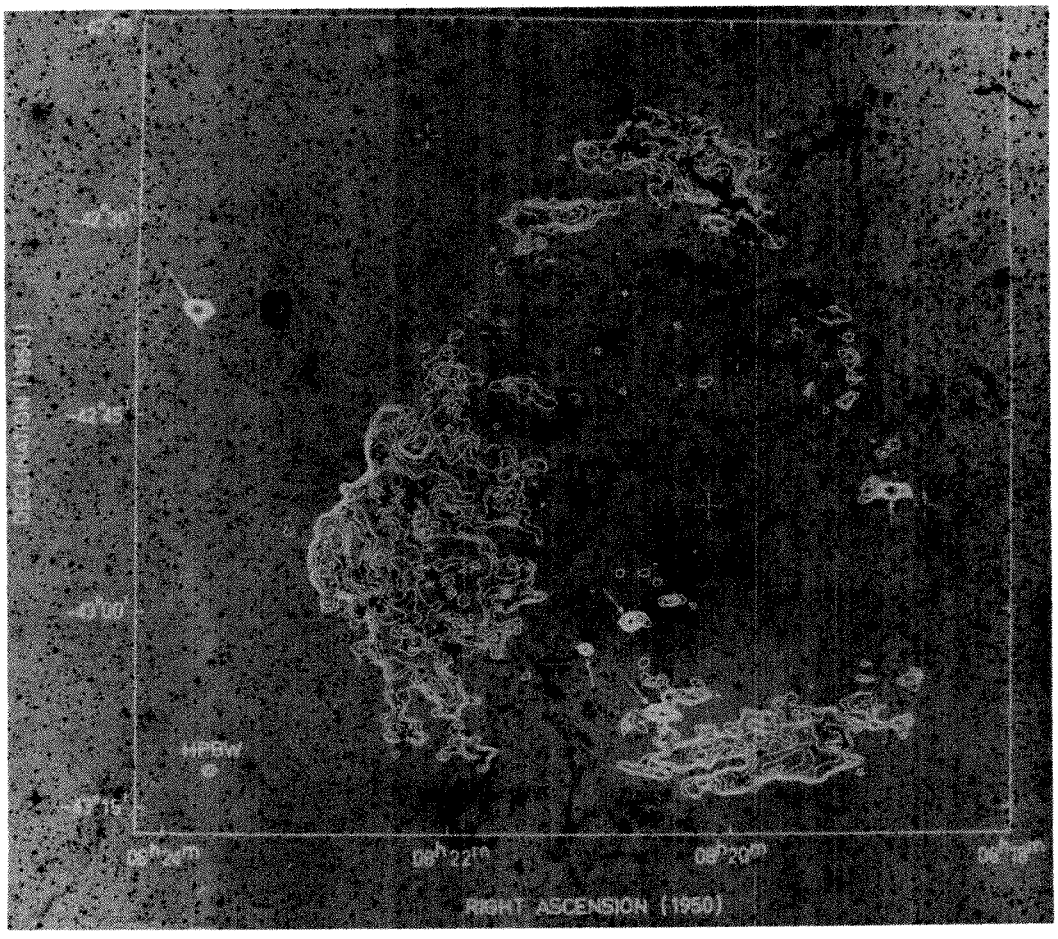

Fig. 1 Radio contours for Puppis A (ref. 2) superimposed on a deep Hα + [N II] plate from the UK Schmidt Telescope[1]. The swirl feature is visible as a group of faint filaments just east of the apparent centre. The 3 × 5 arcmin field for our CCD frames (Fig. 2) is indicated by the corners, and the expansion centre for the oxygen-rich filaments[10] is shown by the black ellipse 3 arcmin to the north-west.

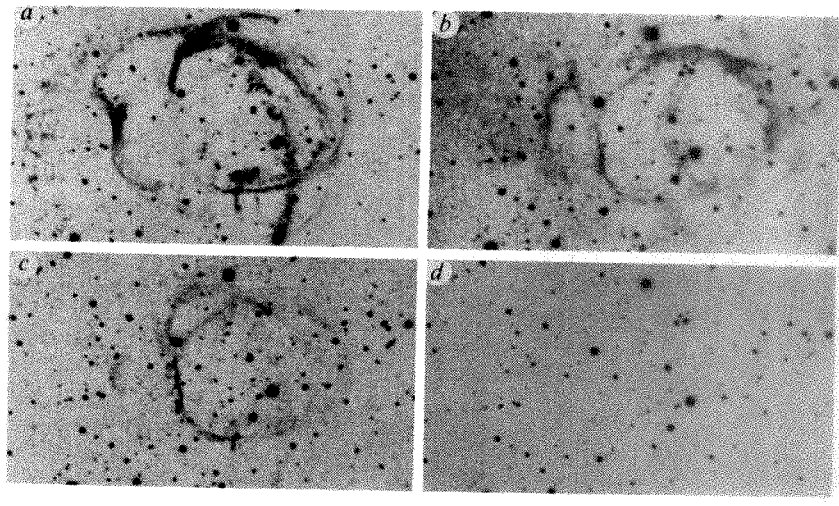

Fig. 2 Narrow-band CCD images of the Puppis A swirl region taken from the CTIO 4-m telescope in the light of Hα + [N II] (*a*), [O III] (*b*), [S II] (*c*), and a 6,100-Å continuum band (*d*). The field is 3 × 5 arcmin; north is up and east is to the left.

single long-slit spectrum with an exposure time of 2,400 s at a position chosen to cross the brightest filaments on the [O III] and Hα + [N II] images. The spectra (Fig. 3) from these filaments are clearly different from those of shock-heated interstellar material and indicate high concentrations of heavy elements. The oxygen filament (Fig. 3*a*) shows strong lines of [O I] and [O II] in addition to [O III], all at a radial velocity of -760 km s^{-1}. Lines of [N II], [Ne III] and faint Balmer lines all have the same radial velocity within the uncertainty of 50 km s^{-1}, which corresponds to about one quarter of the pixel width at 6,000 Å. This spectrum is similar to those of the 'omega' filament, of other fast, oxygen-rich knots in Puppis A (ref. 9), and of oxygen-rich filaments in young SNRs such as Cas A (ref. 11).

Table 1 CCD frames of Puppis A swirl

Ion	λ_c (Å)	$\Delta\lambda$ (Å)	Exposure (s)
[O III]	5,010	50	1,200
Hα + [N II]	6,560	60	600
[S II]	6,720	50	600
Continuum	6,100	150	300

Images taken using the CTIO 4-m telescope, 17 February 1988.

The spectrum of a bright filament from the Hα + [N II] image (Fig. 3*b*) shows that most of the emission is in the [N II] lines: the flux in [N II] 6583 is seven times that in Hα. Although such high [N II]/Hα ratios are quite rare in SNRs, they have been observed previously in bright filaments of Puppis A[4–6]. Nitrogen-rich material could have resulted from pre-supernova mass loss, similar to material in the quasi-stationary flocculi of Cas A (ref. 11) or as observed surrounding SN1987A (ref. 12). What is most unusual in the spectrum of Fig. 3*b* is a high velocity (-990 km s^{-1}) in a nitrogen-dominated filament. This may be a less extreme example of filaments such as the recently discovered 'fast-moving flocculi' in Cas A (ref. 13) which have been interpreted as material from the outer envelope of a Wolf-Rayet progenitor, ejected in the supernova event.

Another set of filaments in the swirl region has a flux in [S II] up to four times higher than in Hα + [N II], and ten times higher than in [O III], as measured on the PFCCD frames of Fig. 2. The strongest [S II] emission lies along an arc which continues to the north as a bright Hα + [N II] filament. No spectra have yet been obtained to confirm that these features are [S II] filaments, but the alternative interpretation, that they are red-shifted Hα + [N II], would require a radial velocity in excess of 5,000 km s^{-1}, over three times higher than any yet measured in Puppis A.

The swirl region comprises the most extraordinary confluence of filaments anywhere in Puppis A, and among known SNRs it is matched only by Cas A in its variety of chemically peculiar debris. If these filaments are part of the Puppis A remnant, some highly unusual mechanism must be proposed to account for their unique morphology, chemistry and velocities. For example, we might be seeing an aneurysm of ejecta, which as it moves outward is confined to a low-density tunnel pointed in our direction, rather like a rifle barrel.

We wish, however, to suggest a more radical interpretation of the data, namely that the swirl region is the remnant of a second supernova which has taken place inside the Puppis A cavity more recently than the event that resulted in Puppis A itself. The evidence for a second supernova consists of the appearance of the optical filaments, the lack of corresponding radio or X-ray features, the unusual chemical composition and the timescale for the swirl expansion.

The morphology of the swirl region is that of a filamentary shell; in particular, the combination of [O III] and [S II] together form an almost complete elliptical shell $\sim 100'' \times 125''$ in size. The absence of associated radio emission rules out the possibility that this shell is simply a chance alignment of a background SNR. The surface brightness of the swirl region is certainly no higher than that of Puppis A itself[2], so its intrinsic diameter should, according to the Σ–D relation, be no smaller. This would require a distance >50 kpc, which is clearly unreasonable despite the uncertainty that attends Σ–D distances.

If the small shell is indeed an SNR, then its surroundings must be extremely unusual to obscure its presence both in the radio and in X-rays. The hot cavity inside an older SNR shell, like that of Puppis A, would provide a high-pressure, low-density environment which could render a second supernova remnant within the cavity undetectable at radio and X-ray frequencies. Instead of leading to a strong shock with associated radio and X-ray emission, most of the kinetic energy from the second supernova would probably re-energize the existing bubble[14]. A related model of a supernova within a cavity has been proposed to explain the X-ray morphology of the young SNR N132D in the Large Magellanic Cloud (LMC)[15]. Optical emission could result if dense knots of ejecta from the second supernova are heated conductively by the surrounding hot plasma. Conduction heating is especially important in metal-rich material, and the spectral characteristics would mimic those of shock excitation[16].

The chemical composition and kinematics of the swirl structure are both indicative of a very young remnant. Its varied, metal-rich filaments are similar to those of Cas A, and the velocities are similar to those measured in other young, oxygen-rich SNRs such as N132D (ref. 17) and 0540-69 (ref. 18) in the LMC, and G292.0 + 1.8 (ref. 19) in our Galaxy. At the distance of Puppis A (2 kpc), the swirl radius of 1 arcmin is equivalent to 0.6 pc, and we have observed radial velocities >750 km s^{-1}

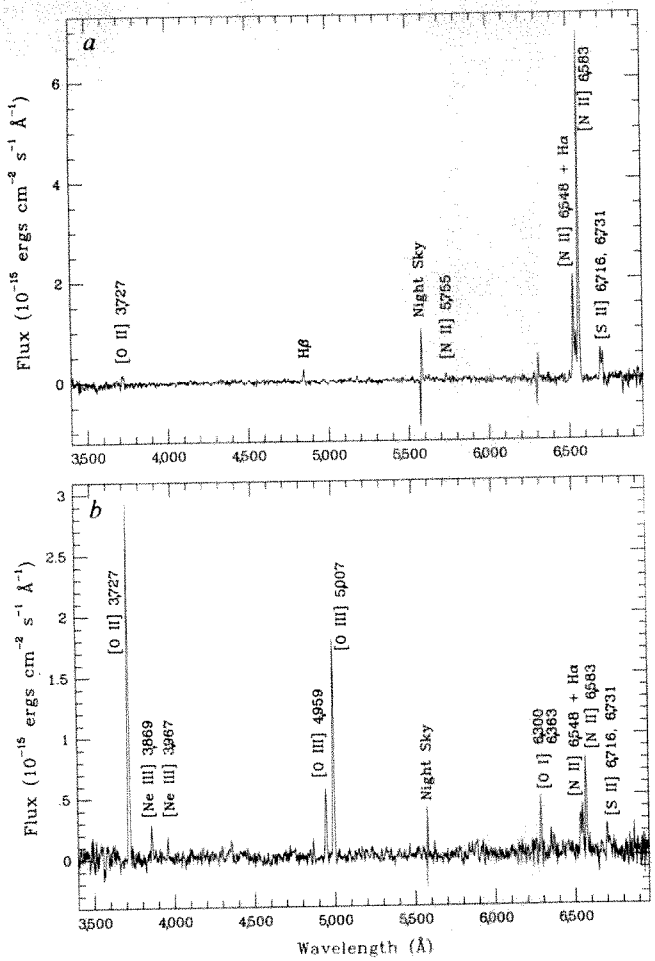

Fig. 3 Spectra of two knots from the same long-slit spectrum taken with the 2-D Frutti on the CTIO 4-m telescope. *a*, The brightest filament in the Hα + [N II] image is radiating primarily in [N II] at −990 km s^{-1}; [S II] is present at the same velocity, and all the oxygen lines are extremely weak. *b*, The brightest knot in the [O III] image shows lines of [O I], [O II] and [O III], all at a radial velocity of −760 km s^{-1}.

for material near the rim. Assuming a comparable transverse velocity, we obtain a timescale of <800 yr for the swirl structure to expand to its present size. By contrast, the kinematic age for Puppis A based on proper motions of the oxygen-rich filaments[9] is 3,700 yr, a value which is in reasonable agreement with age estimates based on the X-ray data.

Kinematic measurements provide potential tests for the 'second supernova' model. At 2 kpc a transverse velocity of 750 km s^{-1} would result in a proper motion of 0.08 arcsec yr^{-1}, so the timescale for the swirl expansion might be measurable within a few years. Meanwhile, more complete radial velocity data may reveal whether the swirl structure is made up entirely of (blue-shifted) material on the near side of the remnant, or whether it is indeed expanding.

Although the 'second supernova' model is speculative, it is interesting enough to merit conjecture about scenarios which could lead to two supernova events in rapid succession. One exotic possibility is that Puppis A was formed from a binary system in which the two components evolved in tandem to explode as near-simultaneous supernovae. The presence of filaments composed largely of oxygen and of oxygen-burning products indicates that Puppis A is the remnant of one or more highly evolved, massive stars, and the nitrogen-rich material suggests a Wolf-Rayet star in particular. Two nearly equal-mass stars in a massive binary system might evolve in tandem with the exchange and loss of mass until the originally more massive one becomes a Wolf-Rayet star and then explodes as a supernova[20–23]. Mass gain by the original secondary would accelerate its evolution until it too becomes a supernova. If the masses are close enough, both components should explode as supernovae within a time interval that is short compared with the evolutionary timescale, possibly producing a remnant such as we observe in Puppis A. Although common models of massive binary systems[24,25] typically assume an initial mass ratio of ~2.5:1 (so that the evolution of the two components proceeds at rates sufficiently different to produce long-lived X-ray binaries), components of nearly equal masses represent the most common configuration observed in unevolved massive binaries[26]. Systems that are balanced delicately enough for both components to explode within a few thousand years would be rare, but possible. Regardless of how they might have occurred, two supernovae within a single shell could comprise the beginning of a supershell, such has been proposed[27–29] to explain the complex structure of the interstellar medium.

The swirl region in Puppis A is comprised of filaments that are spectroscopically, and probably chemically, more diverse than those in any other SNR except Cas A. All the optical properties—irregular shell morphology, peculiar chemistry and relatively high velocities—are characteristic of a young SNR, but the absence of significant radio or X-ray emission is most uncharacteristic. Although the swirl region may be an extraordinary feature of the well-known remnant, we prefer the suggestion that it signifies a second supernova inside Puppis A. Further spectroscopic observations, to investigate the chemical compositions and radial velocities of several filaments, are needed to confirm this interpretation. Proper motion measurements leading to a kinematic age for the swirl structure far younger than that of Puppis A itself might provide a definitive test.

We thank the support staff at CTIO for their assistance with the observations, and Chris Smith for help in preparing the figures. P.F.W., R.P.K. and J.P.H. are visiting astronomers at CTIO, which is operated by AURA, Inc. under contract from the US NSF. This work is supported by the NSF and NASA.

A sub-millimetre aperture synthesis array for nonsolar planet detection

Dayton L. Jones & David J. Diner

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91109, USA

The detection of Earth-like planets orbiting other stars has great scientific interest, but is a challenging observational goal. At wavelengths shorter than 4 μm a terrestrial planet would be about 10^{10} times fainter than a solar-type star, and at a distance of 10 parsecs the planet–star separation would never exceed 0.1 arcsec. At wavelengths longer than 50–100 μm the brightness ratio is reduced by four to five orders of magnitude. Here we consider the possibility of using aperture synthesis to image other planetary systems at sub-millimetre wavelengths (50–1,000 μm). This approach requires only a small increase in dynamic range over that already demonstrated by the Very Large Array at longer wavelengths.

The concepts described here are part of a continuing study to determine which observational techniques could directly detect terrestrial and larger planets orbiting a star within 10 pc of the Sun, using no more than 24 h of observing time per star. This is a considerable challenge at any observing wavelength, but the nature of the challenge differs from radio to infrared and visible wavelengths. At radio wavelengths the primary challenge is obtaining sufficient sensitivity, whereas at infrared and visible wavelengths the primary challenge is obtaining sufficient dynamic range (that is, by suppressing instrumental sidelobes and scattered light for a direct imaging system, or nulling the central star for an infrared or visible interferometer[1–3]).

Using wavelengths longer than ~50 μm has the advantage that the ratio of thermal flux density from a solar-type star and a terrestrial-type planet is orders of magnitude smaller than at shorter wavelengths. In fact, the expected flux density ratio ($\sim 3\times10^{5}$) is only a few times the dynamic range of radio maps currently produced by the Very Large Array (VLA), suggesting that straightforward aperture synthesis could produce images of other planetary systems. At long (radio) wavelengths, however, the absolute flux density of both star and planet decreases rapidly with increasing wavelength, so the region near the peak of the planet's black-body emission should be optimal. Figure 1 shows the spectrum of a terrestrial planet and solar-type star. This letter considers the design of an aperture synthesis imaging instrument operating in this wavelength range (between 50 and 1,000 μm).

The required instrument characteristics are an angular resolution of <0.05 arcsec, a total field of view >2 × 2 arcsec, sufficiently high sensitivity to detect a terrestrial planet at 10 pc in 1 day, and a dynamic range sufficient to prevent sidelobes of the star from hiding a planet~0.1 arcsec away. The ability to image the entire field of interest with full sensitivity at every pixel, and thus to map out the positions of all planets at once, is clearly important as we do not know how complex other planetary systems may be. Resolving planetary disks at such distances is not practical; for example, the angular size of the Earth at 10 pc is only 1 microarcsec.

The resolution and field of view requirements listed above imply baselines from 0.1λ to at least 4λ metres in length, where λ is the observing wavelength in μm. Thus a range of baseline spacings of at least 40 to 1 must be sampled by the array. The field of view also sets an upper limit of 0.1λ metres for the diameter of each individual telescope (in order that the primary beams will not be too small). Otherwise many observations of the region around a target star would be required, greatly reducing the efficiency of the search.

An additional limit imposed by the field of view is the maximum fractional bandwidth. For a heterodyne interferometer it is useful to consider bandwidth in terms of frequency rather than wavelength. The relative response, R, to a source at an angular distance r from the centre of the field is

$$R = \frac{\sin(\pi \Delta\nu\, r/\nu\theta)}{(\pi \Delta\nu\, r/\nu\theta)}$$

where $\Delta\nu$ is the bandwidth, ν is the centre frequency of the observed radiofrequency band, and θ is the width of the synthesized beam. All sources not at the field centre will be radially elongated by $r\,\Delta\nu/\nu$. Preventing significant loss of sensitivity at the field edge requires that $\Delta\nu/\nu \ll \theta/r$. With $r = 2$ arcsec and a synthesized beam smaller than 0.05 arcsec, we need $\Delta\nu/\nu \ll 0.025$. For a multichannel system this limit applies to each individual intermediate frequency channel, not to the combined bandwidth.

The r.m.s. noise (S_n) in an image produced by aperture synthesis with all data weighted equally is given by

$$S_n = \frac{2^{1/2}kT_s}{\eta A[\tau\,\Delta\nu(N(N-1)/2)]^{1/2}}\ \mathrm{W\,m^{-2}\,Hz^{-1}}$$

where the Boltzmann constant $k = 1.38\times10^{-23}$ W Hz^{-1} K^{-1}, T_s is the system temperature, η is the aperture efficiency of the telescopes, A is the physical aperture of a single telescope, τ is the total integration time in seconds and N is the number of individual telescopes in the array.

The minimum total aperture of the array has been calculated assuming telescope efficiencies of 50%, system temperatures of $h\nu/k$ or 50 K, whichever was higher, a total IF bandwidth of 300 GHz (10% of the observing radiofrequency at λ = 100 μm), a total integration time of 1 day, and the use of global fringe fitting[4] (see below). The large IF bandwidth could be produced by combining a large number of parallel channels, but the low system temperature will require significant advances in sub-millimetre mixer or amplifier technology.

The flux density S_p of a planet at temperature T subtending a solid angle of Ω steradians is

$$S_p = \frac{2h\nu^3\Omega}{c^2(e^{h\nu/kT}-1)}\ \mathrm{W\,m^{-2}\,Hz^{-1}}$$

For a terrestrial planet at 10 pc, $S_p \approx 7.3\times10^{-34}$ W m^{-2} Hz^{-1} = 7.3×10^{-8} Jy at 100 μm. We would normally require $S_p/S_n \geq 5$, but if global fringe fitting is used the minimum useful signal-to-noise ratio can be decreased by an additional factor[5] of $\sim\sqrt{N}$.

With these assumptions, the sensitivity requirement implies a total physical aperture NA (collecting area) of $\sim\lambda^2$ m^2, where

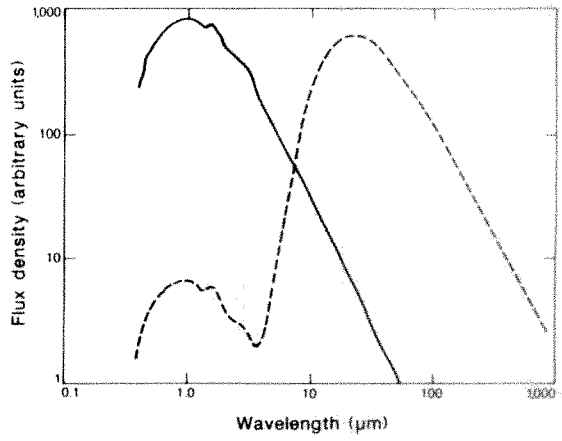

Fig. 1 The flux density of a terrestial planet (dashed line) and a solar-type star (solid line) plotted against wavelength. The curve for the star has been multiplied by 10^{-8}. At wavelengths shorter than ~4 μm the planet flux density comes from reflected starlight; at longer wavelengths it corresponds to thermal black-body emission.

λ in μm. This applies for wavelengths longer than ~300 μm. Because the collecting area of an individual telescope is proportional to λ^2 for a constant beamwidth, the total number of telescopes in the array remains constant ($N \approx 100$ in this example) for wavelengths longer than ~300 μm.

At shorter wavelengths the system temperature increases because of quantum effects ($T_{sys} \approx h\nu/k$), so the required collecting area decreases more slowly with decreasing wavelength. For wavelengths between ~50–300 μm the total aperture of the array is ~300 λ m^2. At wavelengths shorter than ~20 μm the flux density of the planet turns over and the required aperture increases rapidly.

There is a minimum for the total aperture of ~10^4 m^2 at λ = 20–30 μm. Between ~9 and 100 μm the required aperture is within a factor of three of the minimum. This minimum is about 0.7 times the collecting area of the VLA. The detection of planets similar to Jupiter is much easier. Even with only one tenth as much total bandwidth (30 GHz), Jupiter could be detected at 10 pc in 24 hours with a total aperture of ~2×10^3 m^2 in the 20–50 μm region. This is only 15% of the VLA collecting area. Figure 2*a* shows the minimum collecting area as a function of wavelength for both terrestrial and Jupiter-type planets.

Figure 2*b* shows the number of individual telescopes needed for the array as a function of wavelength. At each wavelength, the telescopes are assumed to be as large as the field-of-view requirement allows. This figure makes it clear that the 20–50 μm spectral region is not desirable, despite the fact that it requires the smallest total collecting area. It may be more practical to use a wavelength closer to 300 μm to minimize the total number of telescopes rather than the total collecting area.

All of our sensitivity calculations assume that the total number of telescopes (N) in the array is large (given by the number of 0.1λ-metre diameter telescopes needed to reach the total required collecting area). For example, at λ = 100 μm the maximum individual telescope diameter is 10 m and the total number of telescopes required to detect a terrestrial planet in 1 day is ~250. For a Jupiter-like planet the number of telescopes required is ~40, assuming a 1% bandwidth instead of 10%. There are several advantages to having a large N, including more accurate self-calibration of the individual telescope amplitudes and phases and, as mentioned before, an increase in the total sensitivity of the array by a factor of ~$\sqrt{N}$ through global fringe fitting. However, if a smaller N is desired, the number of IF channels (and thus the total bandwidth) or the total observing time can be increased. As sensitivity is proportional to $\sqrt{\tau \Delta\nu}$ a large increase in τ or $\Delta\nu$ is required to significantly reduce the total collecting area. The maximum integration time is limited by the orbital motion of the planet around its parent star. In the case of a face-on planetary system, a terrestrial planet orbiting a star 10 pc away will move by half the synthesized-beam width in 2 weeks. Thus, if we are willing to accept some smearing of the planet image, the required number of telescopes (or total collecting area) could be reduced from the values given above by about a factor of four, at the expense of observing time.

The individual telescopes must not be so small that fringes cannot be detected on at least one baseline to each telescope. This suggests a hybrid array composed of many telescopes whose size is no larger than that set by the field-of-view requirement, along with one larger telescope whose primary beam may be too small to include any planets. The purpose of this single large telescope is to provide a more sensitive baseline to each of the other telescopes, so that global fringe fitting may be used. As described in detail by Schwab and Cotton[4], global fringe fitting will then be able to detect the weaker fringes on all baselines between the small telescopes. This technique has come into use recently for very-long-baseline interferometry (VLBI) fringe searching.

The relatively large flux density of the star is an advantage here, as it allows the array to be phased up (focused) nearly continuously. By adjusting the individual telescope phases to keep the measured visibility phase from the star equal to zero on every baseline, the much weaker fringes from any planets will be nearly 'stopped' as well. This allows long coherent integrations.

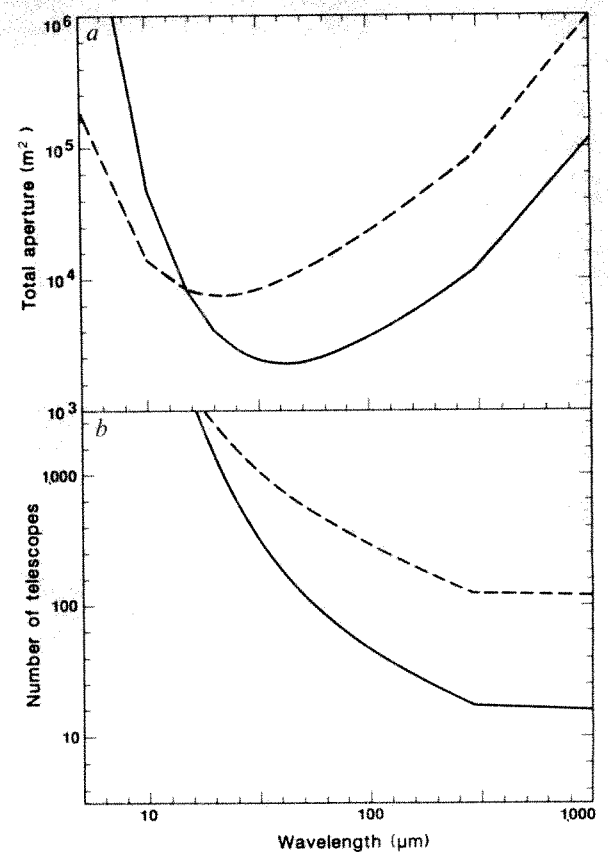

Fig. 2 Minimum total collecting area (*a*) and number of telescopes (*b*) for an aperture synthesis array designed to detect terrestrial planets at a distance of 10 pc in 24 hours. *a*, The dashed curve assumes a 300-GHz bandwidth, 50% aperture efficiency and a system temperature which is the higher of $h\nu/k$ or 50 K. Using wavelengths near 20–30 μm minimizes the required total physical size of the array. The solid curve shows the total aperture required to detect a gas giant planet similar to Jupiter, with the same assumptions as before except for a 30-GHz bandwidth. *b*, Number of telescopes required to provide the array collecting area. As above, the dashed curve is for a terrestrial planet and the solid curve is for a Jupiter-like planet. For wavelengths longer than ~300 μm the numer of telescopes is nearly constant, whereas for shorter wavelengths the number increases rapidly. Note that for the Jupiter-like planet only about 16 telescopes are needed at long wavelengths, assuming a bandwidth of 30 GHz.

The dynamic-range requirement implies that the array must have many separate baselines, and thus a large N, to provide dense and uniform coverage of the aperture (u, v) spectral plane. In addition, the (u, v) coverage should be 'centrally condensed'—that is, there should be more short baselines than long ones. This tends to reduce sidelobe levels in a manner similar to apodization in optical systems. A further requirement for very-high-dynamic-range-aperture synthesis mapping is an absence of errors that are baseline-dependent rather than telescope-dependent. This will require careful attention to polarization response, bandpass response and correlator design.

If we assume that the zodiacal light has a uniform surface brightness within the field of view, then its only effect is to increase the interferometer system temperature and thus the level of thermal noise in the images. The same is true of thermal emission from the telescope mirrors if the temperature remains constant. Both noise sources, if constant, are negligible com-

pared with the heterodyne receiver quantum noise. They may cause problems if spatial structure in the zodiacal light or telescope temperature fluctuations cause systematic variations in apparent fringe amplitude.

The zodiacal light surface brightness is given by

$$B_\nu = \frac{2h\nu^3\varepsilon}{c^2(e^{h\nu/kT}-1)} \text{ W m}^{-2}\text{ Hz}^{-1}\text{ ster}^{-1}$$

For an emissivity ε of 3×10^{-7}, a temperature of 240 K and a wavelength of 100 μm, the surface brightness within a 2 arcsec field of view is about 5% of the flux density of a solar-type star at 10 pc. Thus, fluctuations in zodiacal light at the level of 1 part in 10^4 over sub-arcsecond angular scales, if present, must be discriminated from true planetary signals. Space-based visible or infrared mapping of selected regions of the zodiacal background with sub-arcsecond resolution would constitute a valuable precursor mission.

This project requires that a large number of small telescopes be deployed, which means that the cost per telescope must be small. In addition, the cross-correlation processing load will be very large. The correlator must be able to handle an extremely high data rate ($>10^{14}$ bits per second) because of the large number of baselines $N(N-1)/2$ and large bandwidth (many GHz). For comparison, the digital correlator at the VLA handles 351 baselines and a total bandwidth of 200 MHz. There has been considerable recent progress in the design of large digital correlators, particularly in the development of the FX approach, in which the data from each telescope are Fourier-transformed to the frequency domain before cross-multiplication with all other spectra, which has made very large correlators more practical. Optical cross-correlation is a possibility, although baseline-dependent errors may be more difficult to control with an optical correlator.

A large interferometer array of this sort would be able to meet all of the goals listed above. It would also be an immensely valuable instrument for other areas of astronomical research. Studies of compact extragalactic radio sources, microwave background fluctuations, radio luminosity functions and source counts to very low flux densities are a few obvious examples. The practicality of this approach to nonsolar planet detection is dependent on financial, not basic technical, considerations.

We thank Robert Preston for helpful comments on an earlier version of this paper. This work was done at the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration.

The heavy-ion analyser PICCA[1,2] on the Giotto spacecraft was used to determine the composition and energy distribution of positively charged ions in the coma of comet Halley. Here we argue that the distinct peak observed at mass 39 AMU is due to the aromatic cation $C_3H_3^+$ (cyclopropenyl). Laboratory mass spectroscopy of unsaturated hydrocarbon-chain molecules and aromatics yields large intensities of mass-to-charge ratio (m/z) 39; the spectra of the aromatic molecules also indicate the presence of $C_4H_3^+$ ($m/z=51$) and $C_5H_5^+$ ($m/z=65$). These latter products are not seen in the PICCA data, suggesting that in the cometary environment unsaturated hydrocarbon chains predominate over aromatics. We suggest that the progenitor of the hydrocarbon chains (which are apparently the parents of the $C_3H_3^+$ ion) are the 'CHON' dust particles observed around the comet[3]; the $C_3H_3^+$ ion may also be one of the parent molecules of C_3, which is a common feature of cometary spectra[4], although its origin has remained obscure.

The PICCA (positive-ion-cluster-composition analyser) instrument uses an electrostatic analyser and measures the ratio of energy to charge (E/z). It takes advantage of the large relative fly-by velocity and the fact that cometary ions in the inner coma have very low temperatures (thermal velocity ≪ ram velocity) and are invariably singly charged. Thus the measurements of E/z are, to a very good approximation, proportional to the mass. The mass resolution is $\Delta m = 0.4$ AMU (atomic mass units) in the mass range 10–50 AMU, and $\Delta m = 1$ AMU in the mass range 51–210 AMU. Ions were detected by two channel electron multipliers with different geometric factors to provide a large dynamic range. The spectrum integration time of 3.2 s is different from the spacecraft spin period of 4 s.

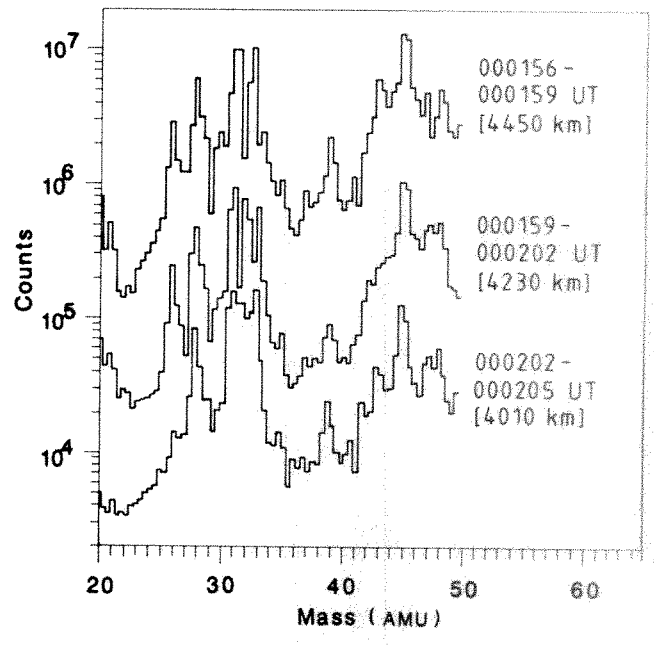

Fig. 1 Three consecutive measurements of mass spectra. The time is given in spacecraft event time and corresponds to cometocentric distances of (top to bottom) 4,450, 4,230 and 4,010 km.

In the following, we show spectra from the PICCA instrument

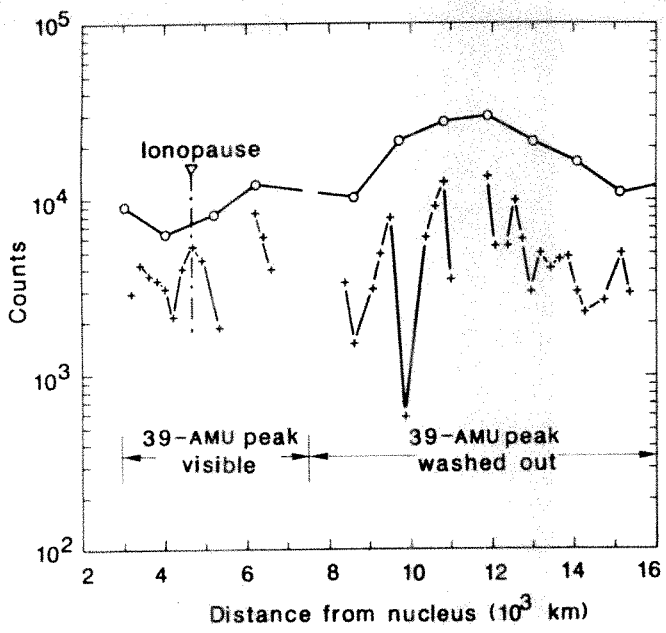

Fig. 2 Radial dependence of the mass channels 39 AMU (+) and 63–73 AMU (○). The intensity, given in counts s^{-1}, is proportional to the density. The position of the ionopause is indicated.

inside the cometary ionopause. The ionopause (which is a tangential discontinuity surface) is the outer boundary of the magnetic-cavity region detected at a cometocentric distance of ~4,600 km during Giotto's inbound passage[5]. In this region, the ion temperatures are as low as 300 K (ref. 6). In this paper, we will discuss peaks in the spectra at masses of 37, 39 and 41 AMU. Although the PICCA instrument measured ions up to 105 AMU, only the part of the spectra close to the peaks of interest are presented here.

In Fig. 1, three consecutive spectra are shown, displaced vertically for clarity. The time is given in spacecraft event time for each spectrum and corresponds to a certain cometocentric distance. The distance from the comet varies from ~4,450 km to ~4,010 km. The count rates correspond to the central spectrum and are proportional to the density. The two other spectra are shifted up and down by half an order of magnitude relative to the central one. The peak at mass 39 AMU which is visible in all three of the displayed spectra can be observed continuously up to cometocentric distances of ~7,500 km with no dramatic change at the ionopause. Outside the ionopause, the thermal-energy spread of the ions limits the effective mass resolution of the instrument so that the peaks get washed out. The transition from sharp to washed-out is not accompanied by a pronounced drop in the count rate (density).

Figure 2 shows the radial dependence of the 39-AMU peak intensity, which is proportional to the density. The density of the 39-AMU species inside the ionopause at ~4,200 km is ~5 ions per cm^3. The values of the intensity for a cometocentric distance $r > 7{,}500$ km are obtained by the fitting process described by Mitchell *et al.*[7]. For comparison, a solid line trace is given which shows the count rates summed from the channels 64–73 AMU (inclusive) and averaged over 16 s. Both curves show similar features, including an intensity maximum between 11,000 and 12,000 km. Unfortunately, it is not possible to deduce a reliable radial profile because of the spin modulation of the instrument and data gaps.

The unambiguous identification of a given peak in the spectra shown in Fig. 1 with a particular ion is not possible. In Table 1, however, we have listed the dominant ion species that are expected from a CHON-dominated medium[8]. As pointed out earlier, we take $z = 1$ (singly charged ions). The PICCA data

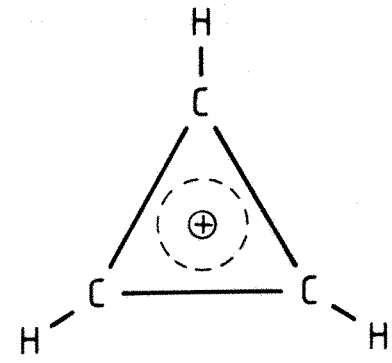

Fig. 3 The structure of $C_3H_3^+$, the cyclopropenyl cation.

show a strong preference for odd mass numbers over even mass numbers; this distribution is typical for a nitrogen-poor non-radical ion mixture. Radical ion species are thus unlikely and are shown in parentheses in Table 1.

The most likely identification of the $m/z = 39$ feature is as the aromatic $C_3H_3^+$ (cyclopropenyl) rather than as a hydrocarbon-chain molecule (see below). The cyclopropenyl ion has a ring structure and shows an aromatic character, having an appropriate number of π electrons (Fig. 3). It has no permanent electric dipole moment and will not be visible in the microwave spectrum.

Although aromatics have a highly unsaturated character, they do not enter into addition reactions and are therefore very stable. Besides $C_3H_3^+$ there are only a few other stable cations with aromatic character. For example $C_7H_7^+$, tropyl ($m/z = 91$), is possibly one of the ions that we identified in the PICCA instrument outside the ionopause.

Inside the ionopause individual mass peaks have been resolved below 70 AMU, whereas outside the ionopause a number of broad mass groups have been observed, one of which is centred at 90 AMU (ref. 9). Contributions to this broad mass group need not come only from an ion of $m/z = 90$, but may also be from ions of neighbouring masses ($m/z = 89$ (dehydrotropyl) and $m/z = 91$ (tropyl)). Although Mitchell *et al.*[9] suggest that $m/z = 90$ corresponds to the ion $HOCH_2CH_2COOH^+$, observed in laboratory residues resulting from simulation experiments[10], $m/z = 91$ could correspond to $C_7H_7^+$, which is known to be very abundant and stable. Recently, Giard *et al.*[11] made the first identification of polycyclic aromatic hydrocarbon molecules in the diffuse emission of the galactic disk.

Laboratory mass spectroscopy of the destruction products of unsaturated hydrocarbon-chain molecules and aromatics shows a pronounced peak at $m/z = 39$ (refs 12, 13). Aromatics also commonly show products at $m/z = 51$ and $C_4H_3^+$ 65. These products, which could be identified as $C_4H_3^+$ and $C_5H_5^+$, are not seen abundantly in the PICCA data. On the other hand, unsaturated hydrocarbon-chain molecules or compounds with oxygen do not show abundant peaks at the above values but instead show peaks at $m/z = 41$ (possibly the cyclopropanyl ion, $C_3H_5^+$) and at $m/z = 43$. The PICCA instrument sees these latter ions rather abundantly. We therefore conclude that the main progenitor of the $m/z = 39$ peak is a long unsaturated chain

Table 1 Possible identification of mass peaks in a CHON-dominated medium

m/z	Ion species
37	C_3H^+, $H^+(H_2O)_2$
39	$C_3H_3^+$, $(C_2NH^{+\cdot})$
41	$C_3H_5^+$, C_2HO^+, $(C_2H_3N^{+\cdot})$

Radicals are enclosed in parentheses.

molecule, although aromatic progenitors are not entirely excluded.

As indicated in Table 1, the 39-AMU mass peak could also be produced by the molecule $C_2NH^{+\cdot}$, assuming only CHON as building blocks. This molecule is a radical, however, and no indications of other homologous radical ions are found in the spectra. Moreover, its reactivity, relative to $C_3H_3^+$, is much higher and therefore there is a high probability of reactions with H_2O, which is the most dominant molecule in the inner coma. The possibility that $m/z = 39$ could also correspond to potassium is ruled out because there is far too little K^+ in the dust to produce such an abundant yield of gas-phase K^+ (ref. 14).

A further decomposition of mass 39 by dehydrogenation to C_3H^+ (mass 37, which is also found, to a lesser extent, in the PICCA spectra (see Fig. 1)) is only possible in high-energy collision processes. These are not likely in an inner cometary coma, where the plasma is very cold ($\leq$300 K). But we note that a significant contribution to the mass-37 peak could also come from $H_5O_2^+$ by the reaction:

$$(H_2O)_2^+ + H_2O \rightarrow H_5O_2^+ + OH$$

if a substantial fraction of water sublimating from the nucleus is in the form of the dimer $(H_2O)_2$ (ref. 15).

We now consider the origin of $C_3H_3^+$. Is it derived from the dust component or from some gas component emanating from the nucleus?. Assuming that the ion of mass 39 participates readily in the atmospheric chemistry, the required abundance of the progenitor molecule can be estimated. The primary gas-phase destruction processes in the cometary atmosphere for any given ion are ion-molecule reactions with H_2O, proceeding at a typical rate $\tau_{im} \approx 10^{-9}\, n_{H_2O}\ s^{-1}$, and recombination, with a rate $\tau_{rec} \approx 10^{-6}\,(300/T_e)^{1/2}\, n_e\ s^{-1}$ (ref. 16). Using a number density for H_2O of $n_{H_2O} = 5\times10^6\ cm^{-3}$ (ref. 17), electron temperature $T_e = 100$ K and electron number density $n_e = 1{,}500\ cm^{-3}$ (from model calculations)[18] at a distance of $3\text{–}4\times10^3$ km, $\tau_{im} = 5\times10^{-3}\ s^{-1}$ and $\tau_{rec} = 2.5\times10^{-3}\ s^{-1}$. This implies that the ion $m/z = 39$ ion must be produced at a rate of $\sim 7\times10^{-3}\, n_{39^+}\ cm^{-3}\ s^{-1}$ (where n_{39^+} is the number density of the ion of mass 39 and $\tau_{rec} + \tau_{im} \equiv \tau_d \approx 7\times10^{-3}\ s^{-1}$ is the total destruction rate).

The production of the $m/z = 39$ ion may occur through either (1) ion-molecule reactions ($X^+ + Y \rightarrow X_{39}^+ + $ products); (2) photoionization of a neutral ($X + h\nu \rightarrow X_{39}^+ + $ products); or (3) photodissociation of an ion ($X^+ + h\nu \rightarrow X_{39}^+ + $ products). Clearly, (1) requires that Y be about as abundant as H_2O because X_{39}^+ is destroyed by H_2O by the analogous reaction. Reaction (2) requires n_x (the number density of X) to be equal to $n_{39^+}(\tau_d/\tau_{pi})$, where τ_{pi} is the photoionization rate. If $\tau_{pi} = 10^{-6}\ s^{-1}$ (a typical photoionization timescale) and $n_{39^+} = 5\ cm^{-3}$, then $n_x = 3.5\times10^4\ cm^{-3}$, which is a density comparable to that of the species, such as NH_3 and CH_4, that are the next most abundant after H_2O and CO. Again, n_x appears to be too large to remain unobserved. Reaction (3) requires $n_{X^+} = n_{39^+}(\tau_d/\alpha)$, where α is the photodissociation rate of X^+. To estimate α we consider the most steeply decreasing mass peak observed between 3,000 km and 4,000 km, which is the mass-75 group, and attribute the entire decrease to photo-processes. Assuming that the ion velocity inside the ionopause is equal to the neutral velocity (a good approximation because of the strong collisional coupling between ions and neutrals there) and taking the latter to be $\approx$0.8 km s^{-1} (ref. 19), we get $\alpha \leq 5\times10^{-4}\ s^{-1}$, and consequently, $n_{X^+} \geq 14\, n_{39^+}$. But the only observed mass peak in the PICCA data beyond mass 39 with a significantly higher intensity is that for $m/z = 45$ (which is $\sim$5 times higher). This is unlikely to produce the $m/z = 39$ ion through reaction (3).

Although the above gas-phase calculations are based on reaction rates that are somewhat uncertain, we believe that they are sufficiently reliable for our conclusions to be valid. Thus we can eliminate a gas-phase progenitor molecule for $C_3H_3^+$, so that the only alternative source that could be significant seems to be the observed circumnuclear CHON dust particles. This is not surprising, as dust has already been strongly implicated as a source of CO (which is the second most abundant species after H_2O, comprising 10–20% of the cometary atmosphere), as well as a source of CN.

Estimation of the rate of volcanism on Venus from reaction rate measurements

Bruce Fegley Jr & Ronald G. Prinn

Department of Earth, Atmospheric and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Maintenance of the global H_2SO_4 clouds on Venus requires volcanism to replenish SO_2, which is continually removed from the atmosphere by reaction with calcium minerals on the planet's surface[1–4]. Here we present laboratory rate data for the reaction between SO_2 and calcite ($CaCO_3$) to form anhydrite ($CaSO_4$). If this reaction rate represents the SO_2 reaction rate on Venus, then all SO_2 in the venusian atmosphere (and thus the clouds) will disappear in 1.9 Myr unless volcanism replenishes the lost SO_2. The required volcanism rate, which depends on the sulphur content of the erupted material, is in the range 0.4–11 km^3 of magma erupted per year. The Venus surface composition at the Venera 13, 14 and Vega 2 landing sites[5,6] implies a volcanism rate of approximately 1 $km^3\ yr^{-1}$. This geochemically estimated rate can be used to determine if either (or neither) of two discordant geophysically estimated rates (2 $km^3\ yr^{-1}$ versus 200–300 $km^3\ yr^{-1}$)[7–9] is correct. It also suggests that Venus may be less volcanically active than the Earth.

Calcite acts as a net sink for SO_2 on Venus by incorporating it into the crust through the net reaction[1–4]

$$CaCO_3\,(\text{calcite}) + SO_2 \rightarrow CaSO_4\,(\text{anhydrite}) + CO \qquad (1)$$

which proceeds to the right because the observed SO_2 abundance on Venus is $\sim$100 times higher than the value in equilibrium with coexisting calcite and anhydrite[4]. Calcite is also predicted by several authors to be present on the Venus surface because it appears to be capable of buffering the CO_2 abundance on Venus through the Urey reaction ($CaCO_3 + SiO_2 = CaSiO_3 + CO_2$)[10–13]. These predictions concerning possible roles for calcite on Venus, the exemplary nature of reaction (1), and the availability of high-purity $CaCO_3$ in several forms led us to study reaction (1) as an example of SO_2 removal processes. However, as

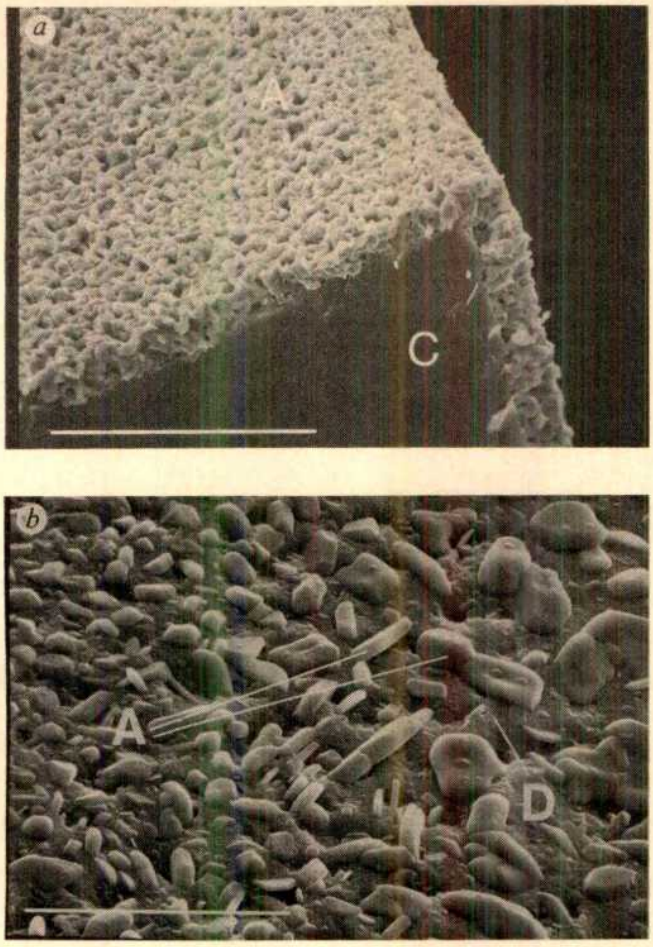

Fig. 1 Scanning electron micrographs of chemically reacted samples. *a*, Fracture surface, showing a $CaSO_4$ (anhydrite) layer (A) completely covering a partially reacted calcite crystal (C) (850 °C for 192 h) *b*, Top surface, showing $CaSO_4$ (A) growing on a partially reacted diopside crystal (D) (833 °C for 48 h). Scale bars indicate 100 μm (*a*) and 50 μm (*b*).

Fig. 1 illustrates, SO_2 also reacts with other calcium minerals (such as, diopside, $CaMgSi_2O_6$), which are believed to be present on the surface of Venus[14,15]. The kinetics for these alternative reactions are also being measured and will be reported later.

Reaction (1) was studied by heating clear calcite crystals (Iceland spar) of known impurity content (~350 p.p.m. total impurities from analysis by inductively coupled plasma emission spectroscopy), weight and surface area in SO_2-bearing gas streams for varying time periods at three different temperatures. Experiments were done at temperatures of 600–850 °C and ambient atmospheric pressures with SO_2–CO_2 gas mixtures nominally containing 1% (by volume) SO_2. Thus, the molecular number density of SO_2 is about the same as that at the surface of Venus, where the atmospheric pressure is ~100 times larger but the SO_2 volume mixing ratio is ~100 times smaller[16]. The mixtures also typically contained <1 p.p.m. O_2 and ≤10 p.p.m. H_2O as impurities. Experiments were also done with gas mixtures containing up to 100 p.p.m. O_2; however, the rates were independent of oxygen fugacity (and thus of the CO/CO_2 ratio) within this range of O_2 content. Standard techniques were used to monitor and control gas flow and temperature (to better than ±5 °C). The rate of reaction (1) was determined by three independent methods: (1) measuring the weight gain at the end of reaction, (2) using scanning electron microscopy (SEM) to measure the porosity and thickness of the reacted surface layers from micrographs of external and fracture surfaces (see, for example, Fig. 1), and (3) SO_4^{2-} analyses of reacted samples by ion chromatography. SEM examination of many samples (in combination with X-ray line scans and energy-dispersive spectroscopy (EDS) on the SEM) showed that $CaSO_4$ layers covered all external surfaces of the reacted samples. X-ray powder patterns of samples and standards confirmed that the layers were anhydrite (in particular, there was no evidence for calcium sulphite) and that unreacted calcite was the only other phase present in the samples. The ion chromatography also verified the absence of anion impurities at levels ≥10 p.p.m.

The experimental run conditions and rate data are summarized in Table 1 and Fig. 2. Rate data using the weight-gain, SEM and SO_4^{2-} analysis methods for the same sample agree within the combined experimental uncertainties (1σ) shown in Table 1. A weighted linear least-squares fit to the data gives a rate equation $R = 10^{19.64(\pm 0.28)} \exp(-15{,}248(\pm 2{,}970)/T)$ molecules $cm^{-2}\,s^{-1}$, with a corresponding activation energy of 126.8 ± 5.4 kJ mol^{-1}. The rate of reaction (1) was extrapolated downward to Venus surface temperatures (~660–750 K) using this equation and the Pioneer Venus radar-altimetry data[17] and atmospheric (P–T) profile[18] to take into account the altitude dependence of the rate. The derived global-mean SO_2 reaction rate is $\sim 4.6 \times 10^{10}$ molecules $cm^{-2}\,s^{-1}$, equivalent to ~1 μm of $CaSO_4$ being deposited per year. However, aeolian weathering[19] by the ~1.0-m s^{-1} winds on Venus[20] will probably remove this thin $CaSO_4$ layer on a shorter timescale, so the laboratory rate data for reaction (1) are applicable to Venus.

Chemical analyses of the Venus surface by the Venera 13, 14 and Vega 2 spacecraft[5,6] give a CaO content (by mass) of $7.90 \pm 0.51\%$ (weighted mean $\pm 1\sigma$); this is also taken as the areal percentage because of similar rock and oxide densities. Assuming that the experimental rate is representative of the rate at which SO_2 is depleted by reaction with calcium minerals on the Venus surface, the observed SO_2 column density (2.2×10^{23} molecules cm^{-2})[16] would be removed from the Venus atmosphere in $\sim 1.9 \times 10^6$ yr in the absence of a comparable sulphur source. However, maintenance of the global H_2SO_4 clouds, which are formed by the ultraviolet-sunlight-powered conver-

Rates determined from independent methods (weight gain (rectangles), SEM (triangles), SO_4^{2-} analyses (circles)) for the same sample agree within the 1σ experimental uncertainties.

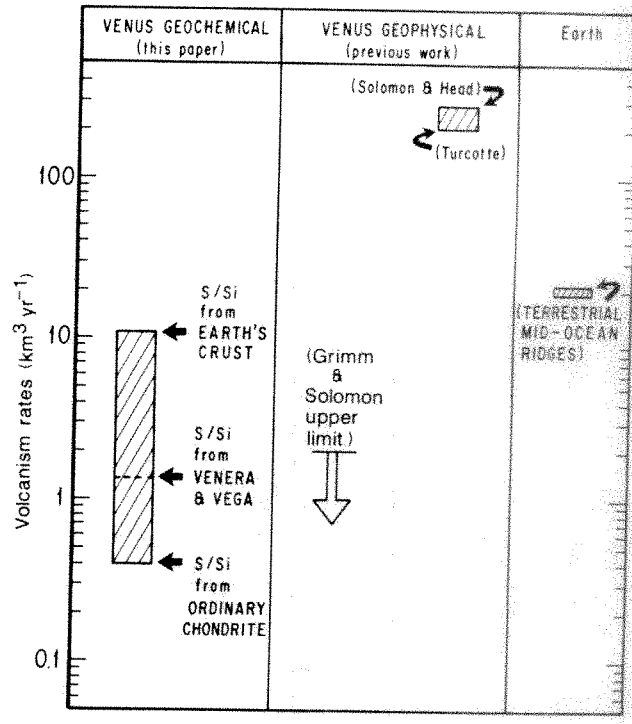

Fig. 3 Geochemical and geophysical estimates of the rate of volcanism on Venus, compared with the terrestrial rate. Three plausible models for the S/Si ratio of erupted material on Venus yield rates of ~0.4 to ~11 km^3 yr^{-1} (see text). Adopting the Venus surface S/Si ratio from Venera 13, 14 and Vega 2 analyses[5,6] yields a rate of ~1 km^3 yr^{-1}, or about 20 times less than the rate of volcanism on Earth. The terrestrial rate of ~20 km^3 yr^{-1} is based on a plate creation rate[27] of ~3 km^2 yr^{-1} and a crustal thickness of ~6 km.

sion of SO_2 into H_2SO_4 cloud particles[21], requires a comparable sulphur source. This source must be endogenic, because infalling cosmic material cannot supply enough sulphur. The calculated SO_2 removal rate on Venus is equivalent to $\sim 2.8 \times 10^{13}$ g sulphur per year. However, the measured terrestrial flux of infalling material, which is roughly applicable to Venus because of similar sizes and masses, is only $\sim 7.8 \times 10^{10}$ g yr^{-1} (ref. 22), or only $\sim 4.6 \times 10^9$ g S yr^{-1} assuming the most sulphur-rich CI chondrite composition[23].

The most plausible endogenic source is volcanism, which has occurred on Venus in the past[24], and which may have led to increased SO_2 levels above the Venus cloud-tops observed by the PV orbiter[25,26]. The rate of volcanism required to balance SO_2 depletion by reactions with calcium minerals on the Venus surface depends on the sulphur content of the erupted material (gas and magma). If this material has an overall sulphur/silicon mass ratio of 0.03 (the weighted mean of the Venera 13, 14 and Vega 2 surface analyses[5,6]), the corresponding rate of volcanism is ~1 km^3 yr^{-1}. Figure 3 illustrates that this rate is ~20 times smaller than the terrestrial value[8,27]. Two other plausible models for the S/Si ratio of the erupted material on Venus are also shown: S/Si ≈ 0.1, as in ordinary chondrites[23], giving a rate of ~0.4 km^3 yr^{-1} and S/Si ≈ 0.004, as in the Earth's crust[28], giving a rate of ~11 km^3 yr^{-1}. All rates will scale as ε^{-1}, where ε is the sulphur degassing efficiency for erupted material ($0 < \varepsilon \leq 1$). However, ε is likely to be close to unity because sulphur gases are expelled directly into the atmosphere, and hot, reactive sulphur-bearing magmas will rapidly lose sulphur to the atmosphere. Our experiments on the chemical weathering by CO_2 of a possible magmatic sulphur-bearing mineral pyrite FeS_2 indicate complete loss of sulphur in hours at sub-magmatic temperatures (~980 °C).

Figure 3 also illustrates that widely discordant volcanism rates have been estimated by two different geophysical methods. Rates of ~200–300 km^3 yr^{-1} are estimated by scaling terrestrial heat production to Venus and transporting the outward heat flux solely by volcanism[8,9], and an upper limit of 2 km^3 yr^{-1} is estimated by analysis of impact-crater areal densities on Venera 15, 16 radar images[7]. The present, geochemically derived volcanism rate is independent of these two methods and can be used, in principal, to test if either (or neither) is correct. In particular, the values computed by the former geophysical method do not agree with our geochemical values. This work also suggests that on average Venus may be less volcanically active than the Earth. Finally, the geochemically estimated volcanism rate can also be used to constrain water loss on Venus through oxidation of FeO-bearing basalt[3]. This work is in progress and will be reported elsewhere.

Laboratory model of a planetary eastward jet

Joël Sommeria*, Steven D. Meyers & Harry L. Swinney

Center for Nonlinear Dynamics and the Department of Physics, University of Texas, Austin, Texas 78712, USA

The concentration of eastward planetary currents into strong wavy jets is a major feature of the atmospheric general circulation (for example, the jet stream) and of oceanic currents (for example, the Gulf Stream east of Cape Hatteras). These strongly nonlinear jets are, however, not well understood. Here we describe experiments in which we have produced similar jets in a rotating annulus with mechanical forcing: the Coriolis force acting on fluid pumped radially inward from a ring of sources to a ring of sinks results in a strong eastward jet. For a wide range of parameters the jet has a robust wavy shape, as shown in Fig. 1. The wave velocity and wavelength of these Rossby waves are accounted for by simple scaling arguments. Experiments with dye injected into the fluid show that the jet acts as a barrier to tracer transport (see Fig. 1*e*), much as the southern polar night jet may act as a barrier to the transport of ozone from lower latitudes into the polar region[1]. Our observations are insensitive to the details of the arrangement of the sinks and sources.

The annular tank (86.4 cm in diameter) is rotated rapidly (up to 4 Hz) to achieve an essentially two-dimensional geostrophic motion, as in large-scale planetary flows. (In a geostrophic flow the Coriolis force is balanced by pressure gradients[2].) The two-dimensionality of our flow is evident in photographs such as Fig. 1*a*, in which particles at different heights in the fluid are seen to produce parallel streaks. The rigidly rotating annulus has an inner radius $r_1 = 10.8$ cm, an outer radius $r_2 = 4r_1$, and a depth that increases linearly with radius from 17.1 cm at r_1 to 20.3 cm at r_2. The conical bottom mimics the beta effect in a planetary atmosphere (the variation of the Coriolis force with latitude). The upper surface of the fluid (water) is in contact with a flat cover. In most of the experiments, including those shown in Fig. 1*a*, *b* and *e*, an eastward jet was produced by pumping fluid continuously from six sources in the bottom of the tank at $r = 35.1$ cm into six sinks at $r = 27.0$ cm; each source and sink consists of 400 holes (0.8 mm in diameter) within a 3.8-cm-diameter circle (these circles are inside the dark disks in Fig. 1*b* and *e*).

For low total pumping rates $F < 20\ \mathrm{cm^3\ s^{-1}}$, each source or sink produces a vortex that stays in the neighbourhood of a port, with sinks producing cyclonic vortices and sources producing anticyclonic vortices. For larger pumping rates, however, the vortices are advected eastward, resulting in a continuous jet. The strength of the jet is controlled by a balance of the total torque arising from the Coriolis force on the radially pumped fluid with the total torque arising from the friction force. The friction arises primarily from the Ekman boundary layers on the top and bottom surfaces of the tank; the tank was made deep to minimize the relative effect of this dissipation. The characteristic time for the dynamics, an oscillation period of the jet, is typically an order of magnitude shorter than the Ekman dissipation time $\tau = h_0/2(\Omega\nu)^{1/2}$ (where h_0 is the mean depth of the fluid, Ω is the angular velocity and ν is the kinematic viscosity); in other words, the Rossby number is typically 0.1. Because the dissipation is weak and the Coriolis force is large, the azimuthal velocity of the jet is typically two orders of magnitude greater than the average radial velocity, and the behaviour of the jet is determined mainly by inertial effects.

The waves on the jet are not attached to the sources and sinks—the crests move eastward with a speed of about 15% of the maximum velocity of the jet. The number of waves varies from 3 to 8, depending on Ω and F (the ranges studied are $6 < \Omega < 25\ \mathrm{rad\ s^{-1}}$ and $15 < F < 370\ \mathrm{cm^3\ s^{-1}}$). For a given Ω and F, the number of waves is reproducible but the wave amplitude and wavelength fluctuate in time. The quasi-steady wave pattern is the result of a balance of westward propagation of Rossby waves and eastward advection.

Quasi-geostrophic flows can be described in terms of the potential vorticity, $q(r, \theta)$, which is given in this situation (that is, uniform fluid density and a topography with a small constant slope) by[2]

$$q = \omega + \beta r \tag{1}$$

where $\omega = (\nabla \times \mathbf{u})_z$ is the vorticity of a fluid parcel relative to the rotating tank, $\beta = 2\Omega s/h_0$ is the coefficient of the beta effect ($s = -0.1$ is the slope of the bottom of the tank), r is the radial coordinate and $\mathbf{u}$ is the fluid velocity. In the absence of viscosity and forcing, q is conserved for each fluid parcel, that is,

$$Dq/Dt \equiv [\partial/\partial t + (\mathbf{u}\cdot\nabla)]q = 0 \tag{2}$$

In our experiment the potential vorticity is nearly conserved—the weak dissipation is balanced on average by the forcing.

The velocity field in the annulus is determined from measurements of the length of particle streaks in time-exposure photographs, such as that in Fig. 1*a*. The velocity vectors from typically 300 particle streaks are fitted with cubic splines[3], and the resultant velocity field is differentiated to determine the potential vorticity at any point in the fluid. We find that there is a steep gradient of potential vorticity in the middle of the jet, as Fig. 1*c* and *d* illustrates, whereas away from the centre of the jet the potential vorticity is fairly uniform. (A gradient in potential vorticity is necessary for the propagation of Rossby waves.) Juckes and McIntyre[4] observed a similar steepening of an initially smooth gradient in their numerical study of a single-layer model of a terrestrial stratospheric polar vortex. At low latitudes the initially axisymmetric flow around the vortex was unstable and rapidly became turbulent, creating a well mixed state, whereas the polar vortex remained an essentially isolated structure. Mixing between these two regions took the form of long thin 'tongues' of potential vorticity and was associated with stratospheric wave-breaking[4–6]. This local steepening of potential vorticity gradients seems to be common behaviour for strongly stirred inertial quasi-geostrophic layers and is similar to the steepening of density gradients observed in strongly stirred stratified non-rotating fluids[7].

In our experiment, injected dye is focused into the jet and renders it visible even when the dye is injected at a radius only occasionally reached by the wave crests or troughs. In a two-dimensional non-divergent flow this convergence must be associ-

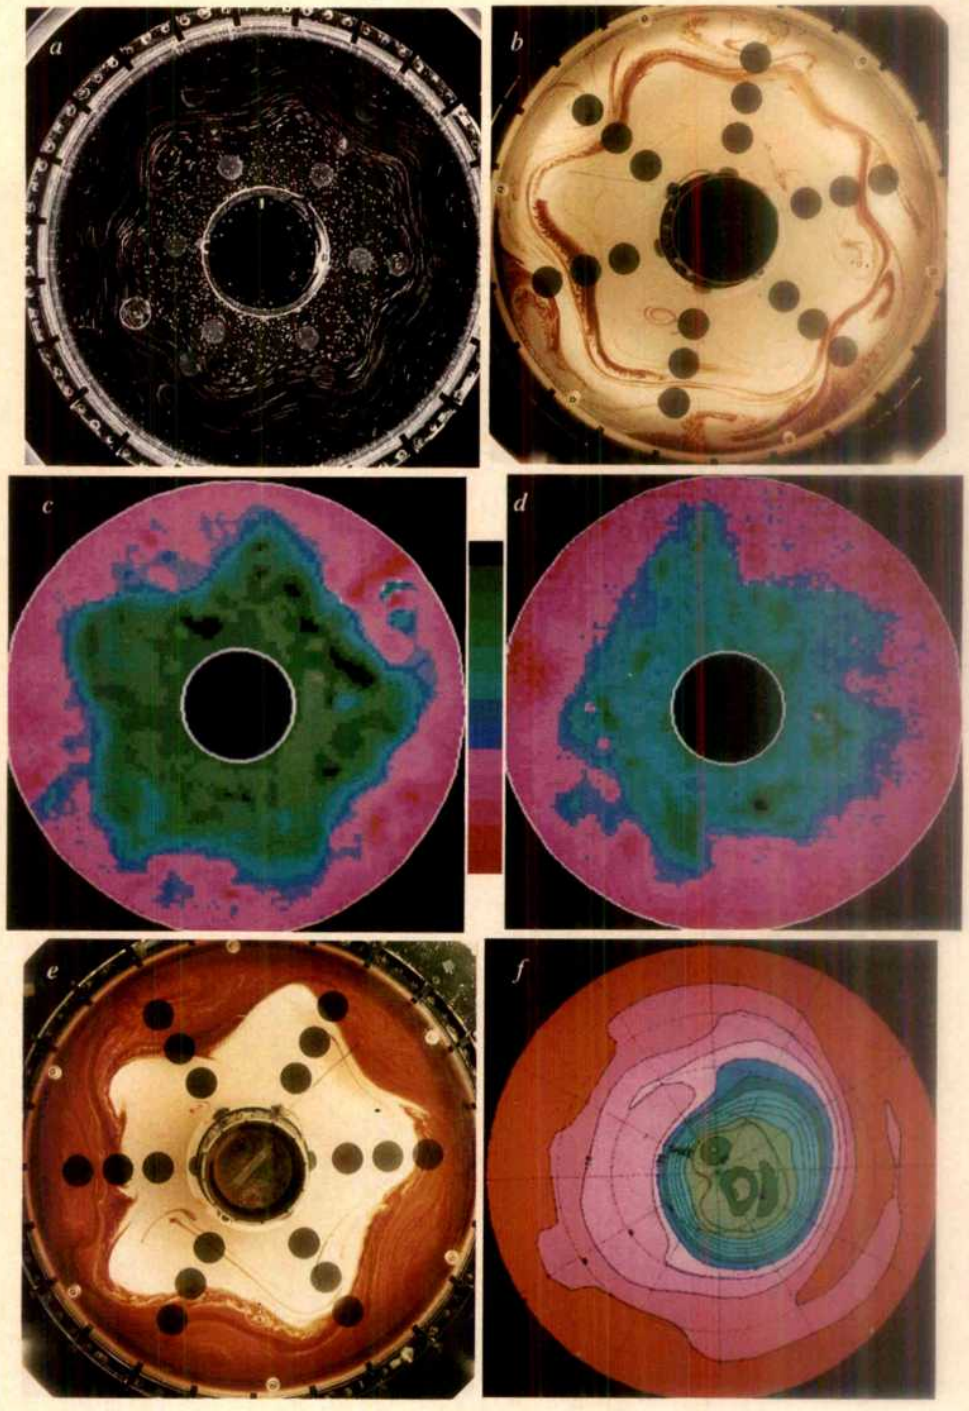

Fig. 1 *a*, A jet with eight waves, visualized with particle streaks photographed in a frame of reference rotating with the tank ($\Omega = 25.1$ rad s^{-1}, $F = 30$ cm^3 s^{-1}; exposure time = 0.5 s). *b*, A jet with seven waves, visualized by continuous injection of dye through a small tube ($\Omega = 18.8$ rad s^{-1}, $F = 40$ cm^3 s^{-1}). *c*, Potential vorticity q for a jet with five waves. The potential vorticity, deduced from particle streak measurements, ranges from -8.1 rad s^{-1} (red) to -0.6 rad s^{-1} (dark green) ($\Omega = 18.8$ rad s^{-1}, $F = 90$ cm^3 s^{-1}). *d*, Potential vorticity q for a jet that formed spontaneously in a slowly decelerating tank with the sources and sinks alternating in a ring at $r = 27.0$ cm. The potential vorticity ranges from -15.0 rad s^{-1} (red) to 2.3 rad s^{-1} (dark green) ($\Omega = 25.1$ rad s^{-1}, decreasing at a rate of 0.012 rad s^{-2}; $F = 137$ cm^3 s^{-1}). *e*, A jet with five waves, photographed more than 500 revolutions of the tank after dye was injected outside the jet ($\Omega = 18.8$ rad s^{-1}, $F = 90$ cm^3 s^{-1}). In *a*, *b* and *e* the jet was produced by pumping fluid from an outer ring of sources to an inner ring of sinks. *f*, Ertel's potential vorticity on an isentropic surface in the upper stratosphere on a calm winter day in the Southern Hemisphere (from ref. 27); contour lines at intervals of 5×10^{-8} Pa^{-1}s^{-1} are distinguished by colour. (The units are those of potential vorticity appropriate to the atmosphere.) A strong potential vorticity gradient in the central region of the jet isolates the polar vortex from the surrounding atmosphere.

ated with an increase of the jet path length, resulting in an increase of the wave amplitude which cannot persist in a steady regime. The growth is limited by a random localized ejection of fluid from the jet which can be observed in the motion of particles suspended in the flow. A particle typically stays inside the jet for several revolutions and is then advected far outward at a wave crest by one of the weak recirculating eddies surrounding the jet. Particles are also advected inwards at wave troughs, but less often. The ejection can be seen in Fig. 1*b* and *e* as tongues of dye. This process slowly fills the space outside the jet with a uniform concentration of dye. When dye is injected far from the jet, it is spread uniformly in the region delimited by the jet, but there is remarkably little transport across the jet for very long periods of time, as Fig. 1*e* illustrates.

These diffusion properties elucidate the dynamics of the potential vorticity, which is advected like a dye; compare the photograph in Fig. 1*e* of a five-wave jet visualized with dye with the plot in Fig. 1*c* of the potential vorticity determined for a five-wave jet. The flow toward the centre of the jet brings the positive potential vorticity produced by the sinks close to the negative potential vorticity produced by the sources, thus inducing a steep gradient. The local ejection of potential vorticity associated with the ejection of fluid particles into the surrounding regions helps to mix potential vorticity and contributes to the small-scale structure seen in Fig. 1*e*. In regions of quasi-uniform potential vorticity the dye spreads quickly and evenly but does not cross the strong potential vorticity gradient in the middle of the jet. The zones of uniform potential vorticity, which cannot support Rossby waves, confine the waves by a nonlinear reflection effect[8,9]. The ejection of particles at wave crests is probably related to the filamentation of potential vorticity observed by Juckes and McIntyre[4], as mentioned above. The

filamentation process has been also observed recently by Dritschel[10] in near-inviscid numerical computations for a circular blob of uniform vorticity surrounded by irrotational fluid. He found that a small perturbation on an initially symmetric vortex creates an irregular region of ever-increasing complexity around the vortex.

Our results are insensitive to the details of the forcing geometry, provided that the flow is eastward with respect to the forcing ports. For example, closing all of the ports on one side of the tank makes virtually no difference to the behaviour of the flow if the total flux F is the same—dye injected away from the centre of the jet is still inhibited from crossing the jet, even in the unforced part of the annulus. Also, a narrow coherent wavy jet is still observed when the distance between the sources and sinks is doubled. A similar, although somewhat less regular, structure is obtained even using a single ring of alternating sources and sinks together with a mean eastward flow produced by a slow deceleration of the tank; see Fig. 1*d*. Seen in a different frame of reference, this situation is equivalent to a forcing that propagates westward in a fluid at rest; this forcing has been used by others[11–13] to demonstrate the production of a mean zonal flow by eddies[14]. In our experiment, in which the effect of friction is less important than in previous experiments, the propagating forcing leads to an inertial eastward jet.

The total angular momentum of the jet results from a balance of the total torque introduced by the forcing with the total torque caused by friction in the boundary layers. This balance leads to the relation $UL = (\Omega \pi d / \pi \langle r \rangle h_0) F$, where the distance d between the rings of sources and sinks is assumed to be small compared with the mean radius $\langle r \rangle$ of these two rings. Here U is a velocity scale and L is the characteristic jet width. Considering the balance between advection and the beta effect yields the classic condition $U/L^2 \approx \beta$. The two relations involving U and L lead to[15]

$$U = a(sd^2/2\pi^2 \nu h_0 \langle r \rangle^2)^{1/3} (F\Omega)^{2/3} \quad (3)$$

$$L = b(h_0 d / 4\pi s \langle r \rangle \nu^{1/2})^{1/3} \Omega^{-1/6} F^{1/3} \quad (4)$$

where a and b are non-dimensional parameters that in general depend on the velocity profile and the exact definitions of U and L. The observed azimuthally averaged velocity, $U(r) = \langle u_\theta(r, \theta) \rangle_\theta$, fits a $\mathrm{sech}^2(r/L)$ profile fairly well for the full range of experimental conditions examined. Moreover, the data are described reasonably well by the scaling relations (3) and (4) with a and b given by the values for a sech^2 profile, $a = (3/8)^{1/3}$ and $b = (1/3)^{1/3}$, as Fig. 2*a* shows for the velocity data. Thus the jet has the same basic structure over a wide range of parameters.

Some qualitative aspects of the jet can be understood using linear theory. Because the perturbations are large, the best form for modelling the zonal flow is not obvious; for simplicity we take the azimuthally averaged flow. The measured profile satisfies the Rayleigh–Kuo criterion of marginal stability[16], which states that the maximum of $\mathrm{d}^2\langle U(y) \rangle / \mathrm{d}y^2$ is equal to $|\beta|$ (where the jet curvature is neglected and y represents the radial direction). When the forcing is turned on, the initially unstable jet profile is broadened by the growth of instabilities until it is stabilized by the beta effect into a marginally stable shape. There are two predicted modes of linear instability, varicose and sinuous, but only the latter is unstable for an eastward jet satisfying the Rayleigh–Kuo marginal stability condition[17]; this explains our observation of a wavy shape. The wavenumber k for the instability is $2^{1/2}L^{-1}$ for a jet with a sech^2 profile. The observed number of waves is in qualitative but not quantitative agreement with this linear theory, as Fig. 2*b* shows. The departure from linear theory is not surprising as the experiments are in a nonlinear regime involving finite amplitude waves and wave-breaking.

Our flow is barotropic (the density is uniform and the velocity field does not vary with height), whereas the atmosphere and oceans are baroclinic (the density and velocity depend on altitude), although planetary-scale flows in the middle stratosphere often exhibit deep vertical structure similar to barotropic flows. Some elegant laboratory studies of Rossby waves have been conducted previously on a baroclinic system, a heated rigidly rotating annulus of water[18–22]. Wavy coherent jets were obtained over a wide range of parameters, but their three-dimensional baroclinic structure is difficult to analyse. We chose to study a barotropic system because it is simpler, yet it exhibits many of the phenomena exhibited by baroclinic flows, including, in particular, Rossby waves. The observation that phenomena found in barotropic flows also occur in baroclinic flows has been termed the 'principle of barotropic analogy' by McWilliams[23].

The behaviour of the potential vorticity in our experiments is analogous to the behaviour of Ertel's potential vorticity in the atmosphere on an isentropic surface[24]. Above the lower troposphere in the Earth's atmosphere, where most of the diabatic and friction effects occur, the flow is dominated by advective effects and Rossby wave propagation; gradients of the potential vorticity on an isentropic surface are due to the tilt of the constant-density surfaces and the curvature of the Earth. Rossby waves propagating westward in an upper atmospheric layer or in the ocean are often amplified by the baroclinic instability[24], just as a steady Rossby wave is amplified by the forcing in our tank. The concentration of the potential vorticity gradient in our jet surrounded by zones of uniform potential

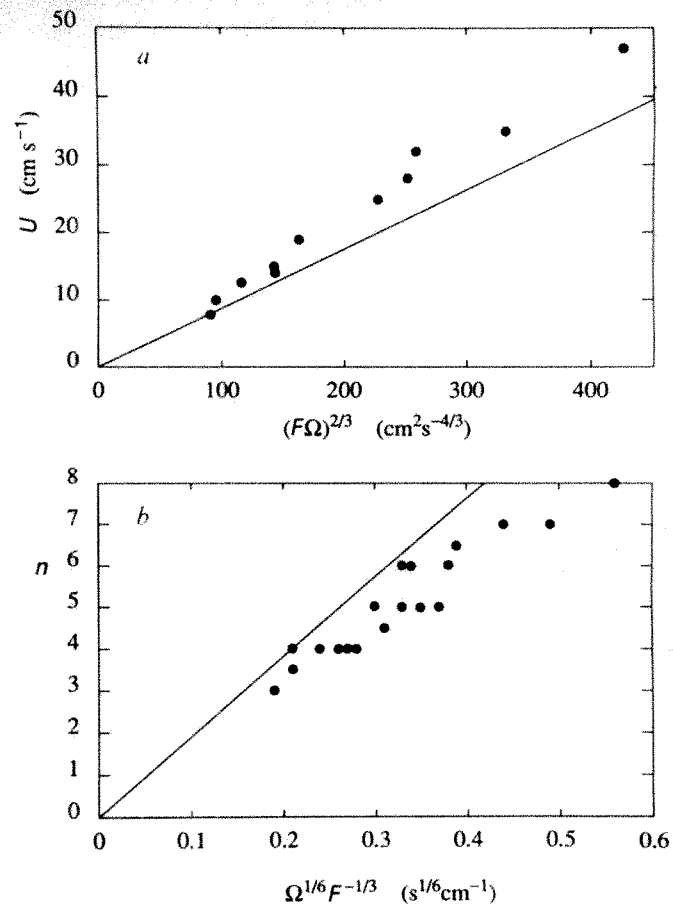

Fig. 2 *a*, The maximum of the azimuthally averaged velocity of the jet, U, compared with the prediction of a marginal stability analysis (diagonal line). *b*, The observed number of waves compared with the value predicted by linear theory (solid line), $n = k\langle r \rangle = 2^{1/2}L^{-1}\langle r \rangle$. In the neighbourhood of a transition the number of waves fluctuates between n and $n+1$; these points are plotted as half-integer values of n.

vorticity is similar to that observed in the atmosphere and the ocean[25,26]; see, for example, Fig. 1*f*. Filamentary mixing across a potential vorticity gradient, such as that illustrated by Fig. 1*e* and *f*, may also play an important role in mixing of atmospheric tracer elements such as ozone[1,27,28].

In conclusion, we have described a relatively simple system for studies of instabilities and turbulence in barotropic jets at high Reynolds number ($\sim 10^5$). Our experiments suggest that jets in planetary scale flows can be inertial structures that are largely independent of the details of the forcing, depending mainly on the total energy and momentum. We find that the wavy eastward jets serve as a striking barrier to particle transport. The potential vorticity barrier has also been found to be remarkably complete in numerical experiments[4]. The laboratory and numerical studies and an analysis of data on the Antarctic atmosphere have led to the vortex-isolation hypothesis of McIntyre[29]: "in the real Antarctic lower stratosphere, the sealing-off of the vortex core from its surroundings might be practically complete".

The narrow wavy structure found for eastward jets in our experiments contrasts markedly with the turbulent flow containing persistent vortices found for westward jets in earlier experiments in the same apparatus[15]. The relevance of these observations to planetary-scale flows should be examined further in future studies.

Geochemical evidence for suppression of pelagic marine productivity at the Cretaceous/Tertiary boundary

James C. Zachos*, Michael A. Arthur* & Walter E. Dean†

* Graduate School of Oceanography, University of Rhode Island, Narragansett, Rhode Island 02882, USA
† US Geological Survey, PO Box 25046, Denver, Colorado 80225, USA

The normal, biologically productive ocean is characterized by a gradient of the $^{13}C/^{12}C$ ratio from surface to deep waters. Here we present stable isotope data from planktonic and benthic microfossils across the Cretaceous/Tertiary boundary in the North pacific, which reveal a rapid and complete breakdown in this biologically mediated gradient. The fluxes of barium (a proxy for organic carbon) and $CaCO_3$ also decrease significantly at the time of the major marine plankton extinctions. The implied substantial reduction in oceanic primary productivity persisted for ~0.5 Myr before the carbon isotope gradient was gradually re-established. In addition, the stable isotope and preservational data indicate that environmental change, including cooling, began at least 200 kyr before the Cretaceous/Tertiary boundary, and a peak warming of ~3 °C occurred 600 kyr after the boundary event.

The section at DSDP Site 577 on the Shatsky Rise (32°26′ N, 157°43′ E) was collected by hydraulic piston core and yielded the first continuous, undisturbed sequence of pure nannofossil ooze (>90% $CaCO_3$) across the Cretaceous/Tertiary (K/T) boundary. Because of the relatively shallow burial depth of the K/T boundary sequence (<110 m below the sea floor (m.b.s.f.)[1]), the calcareous microfossils from Site 577 have not undergone significant recrystallization related to burial[2–4]. The position of the K/T boundary is placed at the last appearance of planktonic foraminifera of the *Abathomphalus mayaroensis* zone[4] and first appearance of calcareous nannofossils of the *Marcalius inversus* zone[2], which also coincides with peak abundance of magnetite-glauconite spherules at 109.09 m.b.s.f. (refs 4, 5). A peak irridium anomaly of 61 ng cm^{-2} also occurs at the boundary, as defined by nannofossils, in adjacent Hole 577B (ref. 6). The palaeodepth of Site 577 is estimated as having been 2,400 m at the time of the K/T boundary[3]. The record at DSDP Site 577 is adequate to resolve the nature of environmental changes in pelagic settings that occurred in conjunction with the K/T boundary event, and provides important constraints on hypotheses for extinction.

To reconstruct changes in the surface-to-deep-water carbon isotope gradient of total dissolved carbon (TDC), stable-isotope analyses were conducted on fine fraction (<63-μm) carbonate and several species of planktonic and benthic foraminifera in closely spaced samples over a 10-m interval spanning the K/T boundary[3,4,7] (Fig. 1). The $\delta^{13}C$ of fine-fraction carbonate (primarily calcareous nannoplankton) and of planktonic foraminifera from this site decreases by about 1.5‰ at the K/T boundary relative to values just below the boundary. The $\delta^{13}C$ values of biserial benthic foraminifera *Aragonia* and of trochospiral benthic foraminifera *Nuttallides*, *Gavelinella* and *Gyroidinoides* show an enrichment across the boundary converging with $\delta^{13}C$ values of both planktonic foraminifera and fine-fraction carbonate just above the boundary (Fig. 2).

Convergence of $\delta^{13}C$ values of planktonic foraminifera, nannoplankton (fine-fraction) and benthic foraminifera indicates that the biologically mediated gradient in carbon isotopes between the surface and deep waters, which is characteristic of productive oceans, effectively disappeared at the K/T boundary. Such conditions have been termed a 'Strangelove' ocean on the basis of predictions for events following a mass extinction[8,9]. The loss of a surface-to-deep-water carbon isotope gradient could only be caused by a major reduction in primary production or by extremely rapid rates of oceanic turnover. At Site 577 the lack of a carbon isotope gradient suggests that a poorly productive ocean persisted for at least 0.5×10^6 yr following the K/T boundary event (Fig. 2). The gradual development of a surface-to-deep-water $\delta^{13}C$ gradient in the period following this interval probably represents a progressive increase in primary production.

The changing offset of $\delta^{13}C$ between biserial and trochospiral

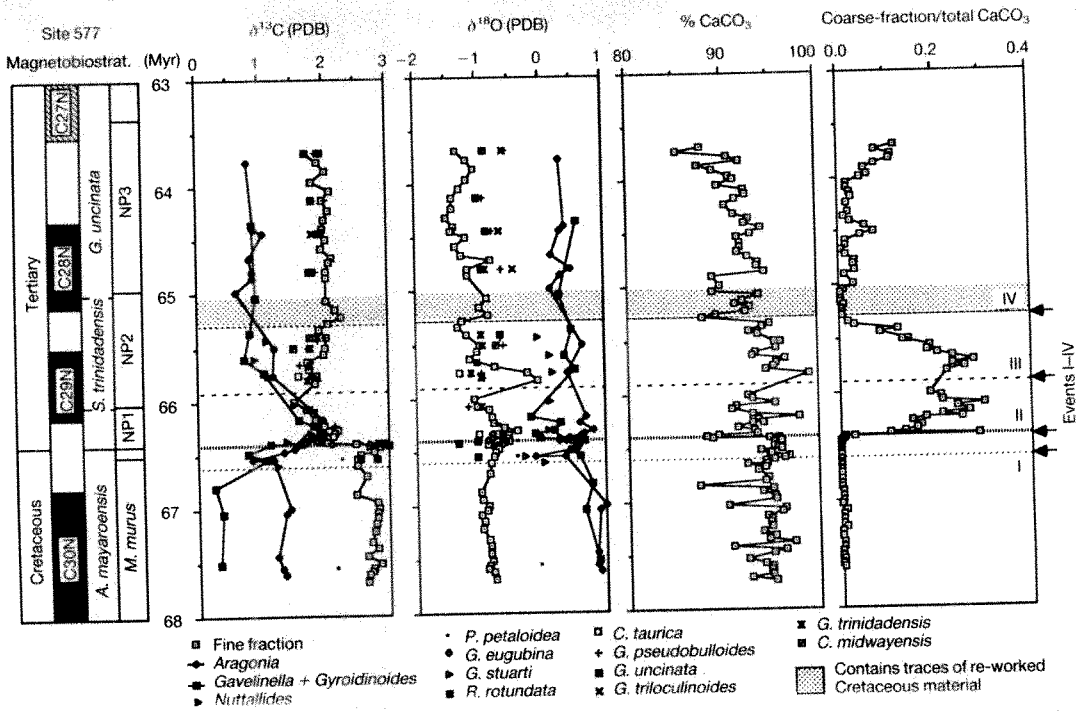

Fig. 1 Age plots of carbon and oxygen stable isotope compositions of fine-fraction carbonate (<63 μm), benthic foraminifer *Aragonia*, trochospiral genera *Gavelinella* + *Gyroidinoides*, and *Nuttallides*, various species of planktonic foraminifera, and carbonate content of whole rock samples. All stable isotope data are expressed in the delta notation, δ, in ‰ relative to the PDB marine carbonate standard[27]. The final column shows the weight ratio (%) of coarse fraction (>63 μm) to total carbonate. Age determinations were made using available magneto-stratigraphy[28] and nannofossil stratigraphy[13] (presented on the far left) and the most recently published timescale[29]. Four separate events are recognized in the evolution of the stable isotope and carbonate content records and are denoted by the four dashed lines. The shaded area represents a portion of the sequence which contains re-worked Cretaceous fossils. The gap in sampling from 65.8 to 65.95 Myr encompasses the interval of an organic geochemistry core removed on board ship.

benthic foraminiferal genera (Fig. 1) is particularly interesting because of the observation that many species of modern benthic foraminifera do not reside directly on the sea floor but instead within the upper few centimetres of sediment, and therefore secrete their tests in carbon isotope equilibrium with the surrounding pore waters rather than with bottom waters[10]. *In situ* decay of organic matter in the upper few centimetres of sediment produces a pore-water $\delta^{13}C$ gradient with a magnitude which is, in part, a function of the accumulation rate of organic carbon (C_{org})[11]. Convergence of $\delta^{13}C$ values of *Aragonia* and that of *Gavelinella* + *Gyroidinoides* across the K/T boundary may indicate that the pore-water $\delta^{13}C$ gradient is eliminated as a result of the reduction in one C_{org} flux to sediments. The absence of benthic foraminiferal carbon isotope differences during the recovery period suggests that new C_{org} flux levels were lower than that of the latest Cretaceous.

Other evidence which suggest earliest Palaeocene reduced primary productivity involves carbonate and barium mass-accumulation-rate data. In the absence of changes in the rate of dissolution, the rate of accumulation of biogenic carbonate should be proportional to production in surface water. Carbonate accumulation rates decline on average by a factor of four across the K/T boundary in all pelagic marine sequences examined[3]. In general, preservation of calcareous microfossils improves across the K/T boundary at most localities[4,12]. Therefore, the decrease in carbonate accumulation rates from Maestrichtian to the early Palaeocene cannot be easily attributed to increased rates of dissolution and must have resulted from a decrease in the rate of $CaCO_3$ production in surface waters.

The distribution of dissolved barium in the modern oceans is nutrient-like and appears to be mediated by biological activity[13,14]. In the modern Pacific Ocean, Ba and organic-carbon sediment-trap fluxes are commonly proportional[15]. Because sediment pore waters are near saturation with respect to barite[16], barite is typically preserved in sediments whereas C_{org} is oxidized. Thus, Ba accumulation rates can be used as a proxy for C_{org} flux to the sediments[17]. At Site 577, Ba accumulation rates decrease from >0.2 to <0.1 mg cm^{-2} per 10^3 yr across the K/T boundary (Fig. 3), reflecting the decreased rain rate of C_{org}.

We have recognized four discrete episodes in the evolution of the stable-isotope and carbonate records across the K/T boundary and in the early Palaeocene at Site 577. The first of these events begins at least 10^5 yr before the main plankton extinctions and the last occurs nearly 1.5×10^6 yr later. We believe that these events represent significant changes in oceanic fertility, circulation and climate, which are accompanied by consequent effects on biotic evolution.

Event I (66.6 Myr), which precedes the K/T boundary event, is marked by enrichment in both planktonic and benthic microfossil carbon isotope records, accompanied by a slight increase in carbonate content and an improvement in microfossil preservation. In addition, Ba accumulation rates decrease. The increase in $\delta^{13}C$ of both the planktonic and benthic records probably indicates a change in $\delta^{13}C$ of the oceanic TDC reservoir. This could have resulted from increased organic-carbon burial on continental margins (or decreased carbon fluxes from weathering) that are related to the latest Cretaceous transgression, which began at about 66.7 Myr (ref. 18). In addition, there may have been changes in deep-water sources, increased oxygenation of deep waters and/or lower organic-carbon flux at Site 577 at this time. Enriched fine-fraction $\delta^{18}O$ values also indicate cooling of surface waters; this suggests that the rate of oceanic turnover and ventilation of the deep reservoir increased before the K/T boundary as the result of global cooling and intensification of thermohaline-driven circulation. The increase in relative proportions of the temperate planktonic foraminiferal

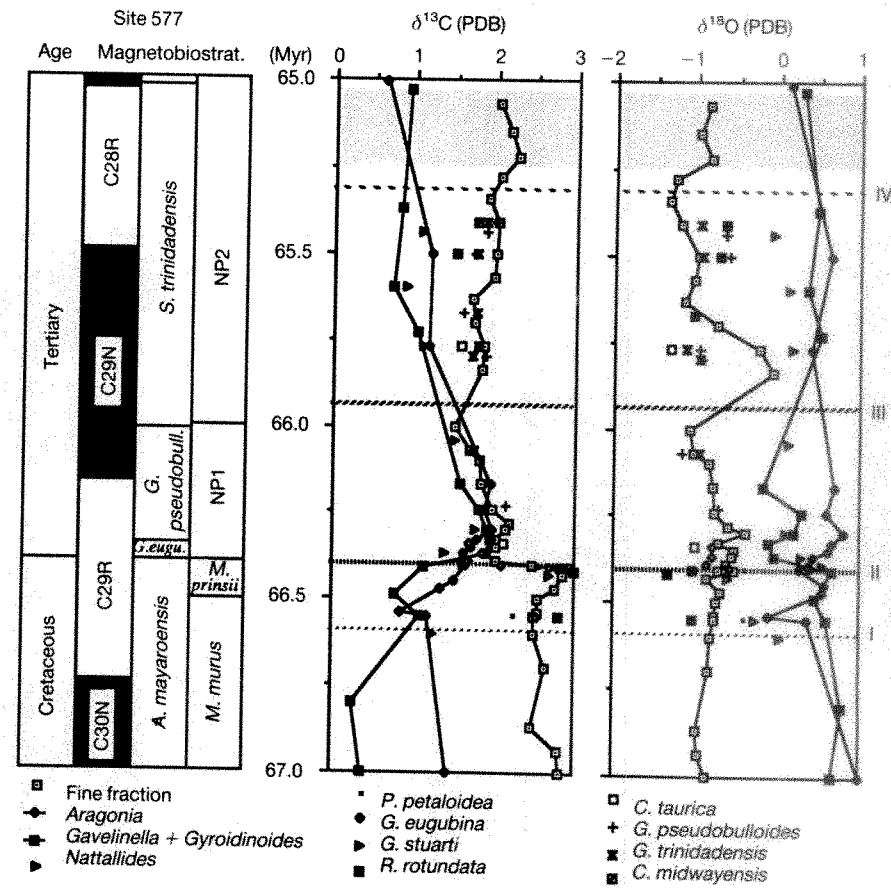

Fig. 2 Expanded 2-Myr record across the K/T boundary of the stable carbon and oxygen isotope data from Fig. 1. Shaded area represents a zone containing traces of re-worked Cretaceous microfossils.

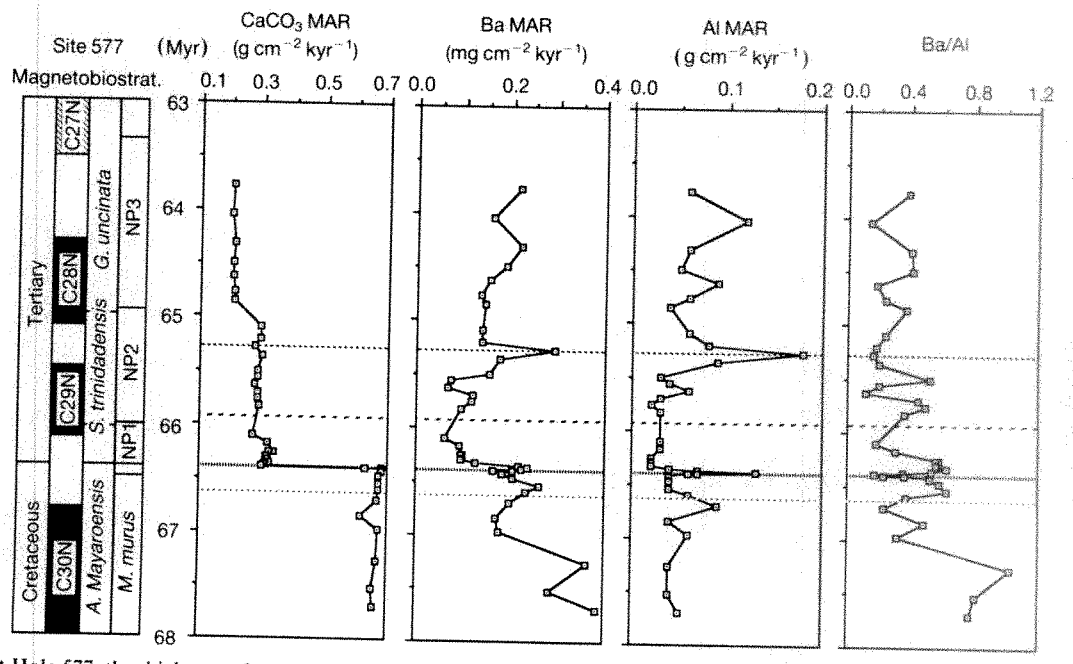

Fig. 3 Age plots of barium (Ba), aluminium (Al) and carbonate mass accumulation rates (MAR), and Ba/Al ratios, at Site 577. The accumulation rates were calculated using physical properties data from the DSDP Leg 86 volume and sedimentation rates based on the magneto- and nannofossil stratigraphy at left. Age assignments for the immediate post-boundary interval were averaged from the top of the Cretaceous (109.1 m.b.s.f., 66.4 Myr) to the base of Chron 29N (108.4 m.b.s.f., 66.17 Myr). As a result, we cannot resolve changes in accumulation rates that occurred on timescales of 10^4 yr or less at Site 577. Because the Base of Chron 30N (C30N) or the *M. murus* zone were not reached at Hole 577, the thickness of the *M. murus* zone (8.48 m) was extrapolated from adjacent Hole 577A. The Ba/Al ratio represents weight ratio of Ba to Al_2O_3.

genus *Heterohelicidae* at this low latitude provides additional support for cooling before the K/T boundary event[4].

Event II: K/T boundary (66.4 Myr), the main plankton extinction and productivity crisis, features the rapid collapse of the surface-to-deep-water carbon isotope gradient and decreases in carbonate and Ba accumulation rates described above. A puzzling aspect of this event is the 100-fold increase recorded in the concentration of foraminifera relative to total carbonate (Fig. 1). There are three possible explanations for this phenomenon: (1) intensified deep circulation resulting in winnowing of the fine fraction; (2) less fragmentation and improved preservation of the more dissolution-susceptible planktonic foraminifera as a result of deepening of the carbonate compensation depth (CCD) and/or lowered rates of *in situ* dissolution brought about by decreased C_{org} decay within sediment pore waters; and (3) an ecological trophic-structure response to the

extinctions and environmental change in which calcareous nannoplankton are replaced by siliceous or organic-walled phytoplankton. We favour preservation changes (2) as the possible origin of the increase in foraminifera concentrations. It is generally accepted that coccoliths tend to be more dissolution-resistant than foraminifera and that calcite dissolution above the calcite saturation horizon is driven mainly by titration by metabolic CO_2 derived from C_{org} decay at or near the sediment–water interface[19]. Dissolution at the shallow palaeodepth of the Shatsky Rise near site 577 would have been controlled to a large extent by metabolic CO_2 production. Decay of C_{org} at the sediment–water interface would decline as a result of reduced C_{org} flux during the 'Strangelove' ocean event making bottom and pore water less corrosive to calcite. Furthermore, taking into account the large initial decrease in $CaCO_3$ accumulation that occurred as a result of the productivity crisis, and assuming that riverine input of inorganic C and alkalinity remained constant, one would expect a rapid deepening of the CCD and much improved preservation of foraminifera across the K/T boundary. Thus we explain the increased foraminiferal flux in the Palaeocene, implied by the higher relative proportion of foraminifers, by enhanced preservation.

Event III (65.9 Myr) is characterized by the gradual return of the surface-to-deep-water carbon isotope gradient, a slight increase in Ba accumulation rates and a gradual decrease in the planktonic foraminifera concentrations. These changes indicate that surface-water productivity began to increase ~0.5 Myr after the K/T boundary event, albeit at relatively low levels. Climate fluctuations of several degrees are indicated by variations in nannofossil and foraminiferal $\delta^{18}O$. Rates of evolution of planktonic forams remained high[20], suggesting continuing environmental instability.

Event IV (65.3 Myr) signals the full expression of the surface-to-deep-water carbon isotope gradient and a decrease in planktonic foraminiferal concentrations to normal values. Aluminium accumulation rates also increased at this time. Because Al accumulation rates are probably a reflection of flux of aeolian detritus to this site[21], the increased Al accumulation rates may represent climate change at this time and possibly an increase in wind strength. Environmental stability is indicated by a nearly constant $\delta^{13}C$ gradient, relatively stable $\delta^{18}O$ values and low rates of change of planktonic foraminiferal faunas in the *G. uncinata* zone[20].

The extinction of phyto- and zooplankton and disappearance of the carbon isotope gradient is abrupt and occurs over a period of less than 10^4 yr. It is unlikely that a gradual environmental change occurring over a longer period of time (that is, 10^5–10^6 yr) could have resulted in such a rapid and extreme collapse of the marine ecosystem unless some as yet unknown environmental threshold was exceeded[22]. The instantaneous environmental stress that would be brought about by a bolide impact provides a possible explanation for the collapse of primary productivity and its coincidence with an abundance of spherules and platinum-group metals at the K/T boundary, as exhibited at Site 577. It fails to explain, however, why primary productivity remained low for such a long period after the event.

It is possible that the 0.5-Myr 'Strangelove' ocean may represent the normal recovery time for the biosphere following a sudden mass extinction event. An alternative explanation is that the slow recovery of primary productivity was the result of climate and oceanic circulation instability. The rate of speciation was extremely high for the first several 10^6 years above the K/T boundary at Site 577, with one assemblage of planktonic foraminifera quickly replacing another[20]. Because the distributions of planktonic foraminifera are limited to particular water masses, the high turnover rate of assemblages suggests that surface-water conditions changed rapidly during the Danian. As a consequence, an efficient, highly structured ecosystem may have been incapable of developing. The origin of this climatic instability is uncertain but may prove to be related to feedback mechanisms involving the global carbon cycle[9,23–25]. Models predict that, following a rapid extinction event, atmospheric p_{CO_2} would have increased by as much as a factor of two or three on a timescale of several oceanic mixing cycles[26], as the result of nearly complete cessation of oceanic productivity. Such increases in p_{CO_2} would be expected to result in global warming. The nannofossil data, which represent the most complete time series, suggest a gradual 3 °C warming of surface waters during the initial 0.5 Myr of the Palaeocene.

A brachiopod calcite record of the oceanic carbon and oxygen isotope shifts at the Permian/Triassic transition

Michał Gruszczyński, Stanisław Hałas*, Antoni Hoffman & Krzysztof Małkowski

The Permian/Triassic (P/T) mass extinction was the most dramatic of all such events but its cause has thus far remained elusive[1–3]. Carbon and oxygen isotope analyses may offer clues to this puzzle because their results identify major changes in the Earth's exosystem[4,5]. Several studies have already dealt with carbon and oxygen isotope records at the P/T transition[2,6–11], but we present here empirical data derived from the brachiopod shell calcite, whose isotope composition generally corresponds to that of the sea water in which the animals lived originally[12–15]. These data allow us to assess quantitatively the magnitude of changes in the Earth's exosystem during that critical time interval.

We sampled the Upper Permian Kapp Starostin Formation[16]

at a number of localities in West Spitsbergen (Fig. 1). This formation consists mainly of cherts and carbonates associated with fine-grained terrigenous deposits, which accumulated in open marine environments of a broad epicontinental sea[17]. The conodonts found in the section at Kapp Starostin demonstrate the latest Leonardian age of the basal part of the formation and strongly suggest a Changsinghian (latest Permian) age for the upper part of the section[18]. In central West Spitsbergen, deposits of the Kapp Starostin Formation pass, without any evidence for discontinuity, into the overlying marly shales of the Vardebukta Formation[19], which contain, in this area, Griesbachian (early Triassic) conodonts[20] and molluscs[21] and, higher up, Dienerian ammonoids[22]. Thus the area appears to represent one of the few continuous stratigraphic records across the P/T transition. Time correlation among individual sections within the Kapp Starostin Formation (Fig. 2) has been achieved by means of event stratigraphy[23].

The samples we analysed for carbon and oxygen isotopes are brachiopod shells with fully preserved primary microstructure and without any evidence for allochthoneity. To ensure consistency of the isotope analysis, we focused on a single brachiopod taxon, the Productacea (although we also took some other fossil and rock samples for comparative purposes). This material is particularly suitable for such study because brachiopods fractionate only insignificantly the carbon and oxygen isotopes they take up from the sea water for shell development, and the isotope composition of their low-magnesium calcite is generally not affected by the diagenetic alterations that so often obscure the chemistry of rock matrix and skeletal calcite[12-15,25-27].

The carbon and oxygen isotope composition of our samples was determined by mass spectrometry on CO_2, obtained by calcite reaction with 100% H_3PO_4; the standard error of single measurements is less than 0.08‰ (ref. 28). The results are expressed here in $\delta^{13}C$ and $\delta^{18}O$ notation (relative to the PDB standard, using the NBS-19 reference sample).

The brachiopod-bearing facies occurs in West Spitsbergen throughout the entire time interval represented by the Kapp Starostin Formation, but discontinuously in each section. Therefore, we employed the event-stratigraphic time correlation to produce composite curves of changes in the carbon and oxygen isotope ratios (Fig. 3). The productacean samples yield a very clear pattern. The supplementary samples show a little more variation, but they nevertheless largely follow the productacean pattern. As clearly demonstrated by a comparison of Figs 2 and 3, the stratigraphic sequence of carbon isotope measurements taken on samples collected from each particular section is invariably consistent with the overall pattern, so that the most striking features of the pattern are in fact documented within individual sections. This comparison ensures the reliability of our composite curves as an orderly stratigraphic record.

The lower part of the carbon isotope curve from the Kapp Starostin Formation scatters around a $\delta^{13}C$ value of +4‰, which is typical of measurements taken on a variety of Permian rocks from all over the world[5-11,14,29,33]. In the middle part of the section, $\delta^{13}C$ increases rapidly by as much as 3.5‰, a phenomenon recorded also in many other sections[2,5-9,30,34]. The upper part of the curve shows a dramatic decline of $\delta^{13}C$ by more than 10‰, falling to pronouncedly negative values. A distinct drop in the carbon isotope ratio at the P/T transition occurs also in Transcaucasian[2], Chinese[10] and Alpine sections[11], but nowhere has it been observed to be of such extraordinary magnitude. Thus, the carbon isotope curve obtained in West Spitsbergen is generally consistent with all the data reported previously. Given the biostratigraphic data we have, the timespan of the two carbon isotope shifts together is of the order of a few million years. The oxygen isotope curve essentially mimics the carbon curve, although its decline in the uppermost part of the Kapp Starostin Formation is slightly less dramatic, presumably due to a regional cooling[35].

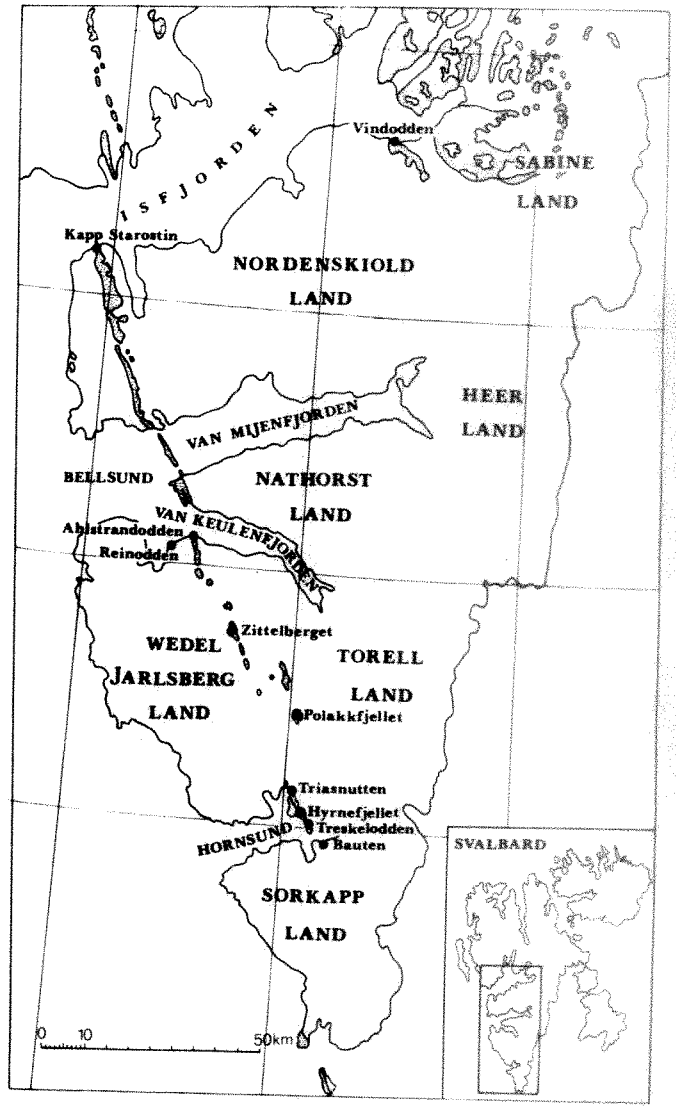

Fig. 1 Location map of the outcrops (shaded areas) of the Kapp Starostin Formation in West Spitsbergen.

To ensure that these carbon and oxygen isotope patterns are not biased by diagenetic alterations, we tested our brachiopod shell material for minor-element proportions. The results of this analysis are presented in Fig. 4 and show that our brachiopod calcite material has not been substantially altered (compare refs 14 and 15); they also show that the samples with extreme $\delta^{13}C$ values, which essentially determine the isotope patterns, do not significantly deviate from the others in this respect. It is worth noting, moreover, that even severe diagenetic changes under the influence of meteoric water have not been reported to effect a change of more than 2–4‰ in $\delta^{18}O$, as compared to the 7‰ shift we observe, and could not possibly lead to the $\delta^{18}O$ values as extreme as −11‰ that we find[36-38]. Having thus ruled out the possibility of diagenetic controls on our empirical pattern, we must interpret the covarying curves of $\delta^{13}C$ and $\delta^{18}O$ as reflecting a global process in the Earth's exosystem.

In this perspective, the magnitude of the carbon isotope shifts is the most extraordinary feature of the pattern. The carbon isotope curve implies that the Late Permian ocean was at first relatively impoverished (spike) and then enriched (drop) in the light isotope of carbon. Relative impoverishment in the light isotope indicates removal of isotopically light organic carbon

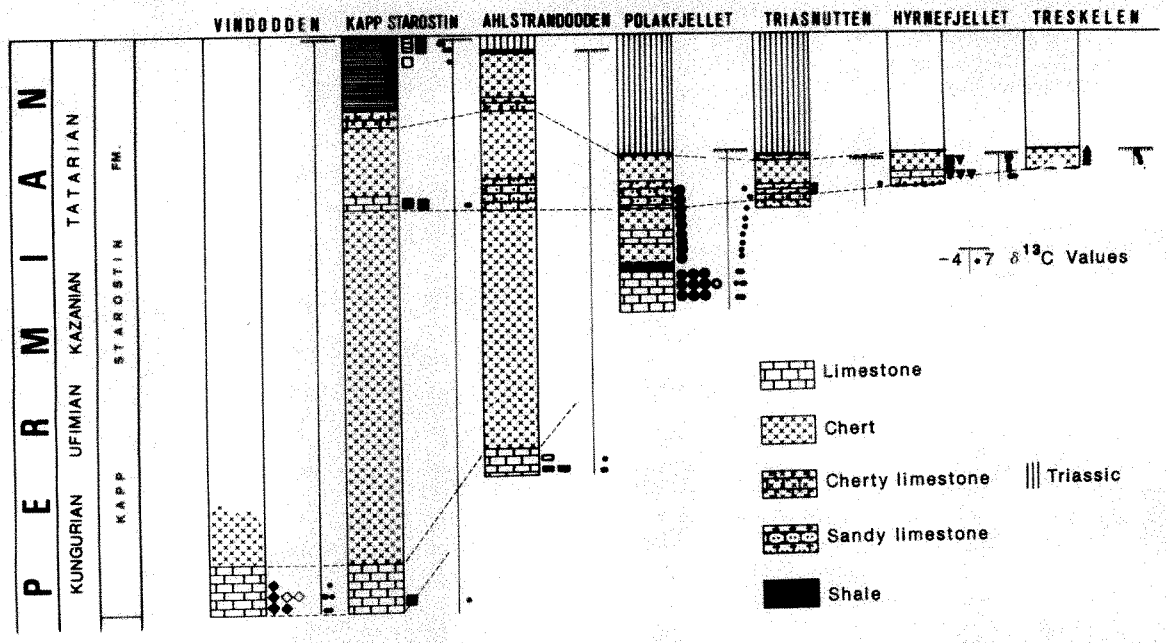

Fig. 2 Time correlation of the investigated sections and sample location; closed symbols denote productacean brachiopod shell material, open symbols indicate other fossil and bulk rock material; $\delta^{13}C$ values for individual samples are shown graphically; bold lines in the bar charts denote the P/T boundary; dashed lines are time correlation lines.

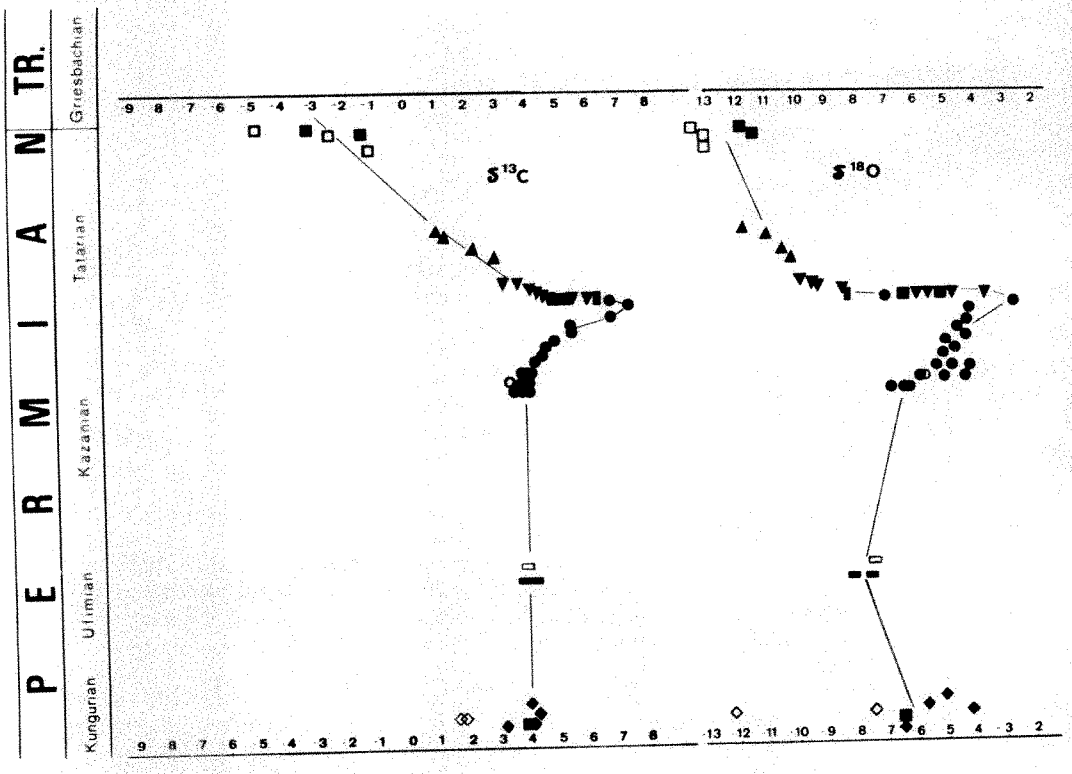

Fig. 3 Carbon and oxygen isotope curves obtained for the Kapp Starostin Formation; sample symbols are as in Fig. 2.

from the ocean-atmosphere system, that is, increased burial rates; relative enrichment, in turn, may be explained either by diminished burial rates of organic carbon, by diminished uptake of the light isotope by the biosphere, or by its increased input to the system, in the form of organic carbon from land ($\delta^{13}C$ of −25‰), marine deposits (−15 to −20‰), or as juvenile, volcanic carbon dioxide ($\delta^{13}C$ of −5‰). Spitzy and Degens[39] have derived a formula to calculate the amount of carbon with a particular isotopic composition that must be supplied to, or removed from, the reservoir with a given isotope ratio in order to cause a specified shift in $\delta^{13}C$:

$$N_B = N_A \cdot \frac{\left[1+\delta_{std}\cdot\left(1+\frac{\delta_B}{1{,}000}\right)\right](\delta_A-\delta_M)}{\left[1+\delta_{std}\cdot\left(1+\frac{\delta_A}{1{,}000}\right)\right](\delta_M-\delta_B)}$$

where N_A is the initial reservoir mass of carbon, N_B is the perturbing mass and δs denote the isotopic compositions in standard notation, with subscripts indicating the initial (A), the

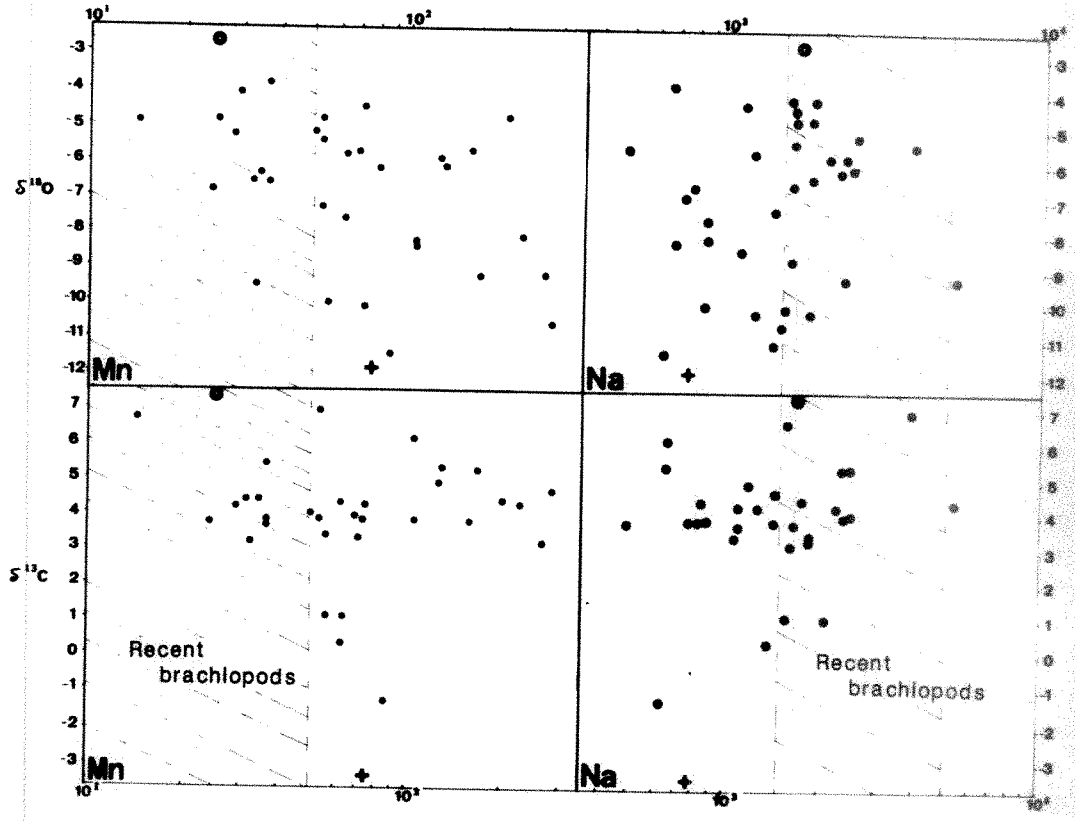

Fig. 4 Manganese and sodium proportions in the productacean shell samples analysed for carbon and oxygen isotopes, as compared with the values typically obtained in Recent brachiopods, show no diagenetic trends in the material (cf. refs 14 and 15); samples with extremely positive (circle) and extremely negative (cross) $\delta^{13}C$ are indicated. Shaded regions include Recent brachiopods.

perturbing (B), the resulting (M) and the reference standard (Std) values. From this equation and assuming that the Late Permian ocean contained as much carbon as the present one (4×10^{13} tonnes), the amount of volcanic carbon necessary to cause the latest Permian drop in $\delta^{13}C$ would demand an increase in juvenile carbon dioxide supply by three orders of magnitude, which is implausible. Hence, organic carbon must have been shifted from one reservoir to another. Assuming that the organic carbon shifted had a $\delta^{13}C$ value of −15‰ and that the Late Permian biosphere contained as much carbon as the present one (5.6×10^{11} tonnes), the positive spike in $\delta^{13}C$ which we observe is equivalent to removal from the ocean-atmosphere system of more than ten times the total amount of carbon in the living biosphere; the subsequent drop in $\delta^{13}C$ is equivalent to input of organic carbon in amounts comparable to the total carbon content in the ocean, or two orders of magnitude more than the total living biomass. Neither a complete cessation of carbon uptake by the biosphere (as a result of its total extinction) nor a dramatic decrease in organic matter burial could account for such a rise in the amounts of isotopically light carbon contained in the ocean.

Hence, the global process reflected by our carbon isotope curve can only be envisaged as increased burial of organic matter (spike) followed by its oxidation (drop). This interpretation is indeed consistent with our oxygen isotope curve, because oxidation of organic matter, reflected by a drop in $\delta^{13}C$, must lead—through kinetic fractionation processes—to a decline in $\delta^{18}O$ as measured in all species of dissolved oxidized carbon[40].

As we deal here with changes in isotope composition of the sea water, the most efficient explanation for our empirical pattern is that both the initial burial and the subsequent oxidation of organic matter occurred in the ocean, rather than in another carbon reservoir. A similar phenomenon took place at the Precambrian/Cambrian transition[41]. This phenomenon can be explained by oxidation of organic matter accumulated previously in the ocean simply because continents were barren at the time and could not yet provide large amounts of organic carbon. Our data thus indicate very high depositional rates of organic matter in the Late Permian ocean, which were replaced at the P/T transition by its extensive oxidation.

This conclusion has tremendous implications for the history of the ocean–atmosphere system and, consequently, life. The increased burial in the ocean must have left much oxygen free. Under the resultant reducing conditions at the sea bottom, phosphorus and nitrogen recycling was enhanced[42]. The subsequent oxidation of organic matter, however, must have drawn much oxygen from the atmosphere, and oceanic phosphorus and nitrogen then sank to the sea floor because of their oxidation[43]. The resulting decline in atmospheric oxygen levels and nutrient deficiency could be the main causes of mass extinction at the P/T transition.

Peat acidification in Scotland

U. Skiba*, M. S. Cresser*, R. G. Derwent† & D. W. Futty‡

‡ Land Use Division, The Macaulay Land Use Research Institute, Craigiebuckler, Aberdeen AB9 2QJ, UK

Simulation experiments have shown that soils can become more acid when treated with accelerated loads of acid precipitation[1–3]. Field observations, however, give less clearcut answers. Acid deposition is rarely the only variable between sites, and effects are too small for soil *p*H changes to be measurable over much less than a decade. To circumvent these problems, Hallbacken and Tamm[4] in Sweden and Billett *et al.*[5] in Scotland re-sampled soil profiles in forests after 39–57 years and showed that many surface organic and mineral horizons had acidified, but biological acidification and acid deposition may both be implicated in the observed changes[5]. Here we compare peat acidity and base saturation with modelled acid deposition at 123 sites in Scotland. Peats with highest acidity ($pH(CaCl_2) \leq 3.0$) and with lowest base saturation ($\leq 10\%$) are found mainly where deposited acidity was greater than 0.8 kg H^+ ha^{-1} yr^{-1}, providing conclusive evidence that acid deposition plays an important part in the acidification of some soils.

Dystrophic and dystrophic-flushed peats are believed to be particularly susceptible to acid deposition. The surface layers of such peats rely directly upon ion-exchange properties and precipitation for the supply of cations and anions. Acid precipitation increases the leaching of cations from organic soils[3]; exchangeable cations are replaced by H^+ from the incoming precipitation. For soils with only thin organic layers, leached cations may be replaced by biogeochemical weathering in the underlying mineral layers and by element cycling. Ions may be transported upwards from the mineral soil into the organic layer by roots penetrating into the underlying deeper horizons, and also by periodic rises of the water table. In soils such as peat, in which the organic horizons are thick ($\geq$0.5 m), this mechanism works only to a very limited extent[6]. Therefore the surface of dystrophic and dystrophic-flushed peats should reflect deposition chemistry rather than underlying soil mineralogy, and can be a valuable tool in estimating the effects of rain chemistry on peat chemistry.

We have compared the peat chemistry and a model of acid deposition at 123 sites in Scotland. Data on the chemistry of hill peats were extracted from the Scottish National Soil Inventory set up by the Macaulay Land Use Research Institute (Aberdeen). Soil samples for this inventory were collected after 1978. They were air-dried at 30 °C, and 2-mm-sieved samples were stored until analysis, usually within a year. Soils are classified as peat when the organic matter was at least 0.5 m thick. Only dystrophic and dystrophic-flushed peats, collected from sites where the slope form was straight or convex, were included in this study. Most peat samples were collected from the top 15 cm of the peat horizon, some from the top 20 cm and three samples from the top 25 cm. Samples were analysed for *p*H ($CaCl_2$) and percentage of base saturation at the Macaulay Institute, using standard methods. Peat *p*H and base saturation were plotted and their distribution in Scotland was compared with total wet- and dry-deposited acidity calculated for each peat sampling site using the Harwell trajectory model[7]. Deposited acidity at each sampling site was estimated by including contributions from both dry- and wet-deposition routes, and from acidic sulphur (SO_x), nitrogen (NO_x) and chlorine (HCl) pollutants emitted from sources within the United Kingdom and the rest of Europe. Total wet- and dry-deposited acidity was expressed in kg H^+ ha^{-1} yr^{-1}, assuming that 2 g H^+ are equivalent to 32 g S, 1 g H^+ to 14 g N and 1 g H^+ to 35.5 g Cl, and making no adjustment for the deposition of ammonia and its derivatives.

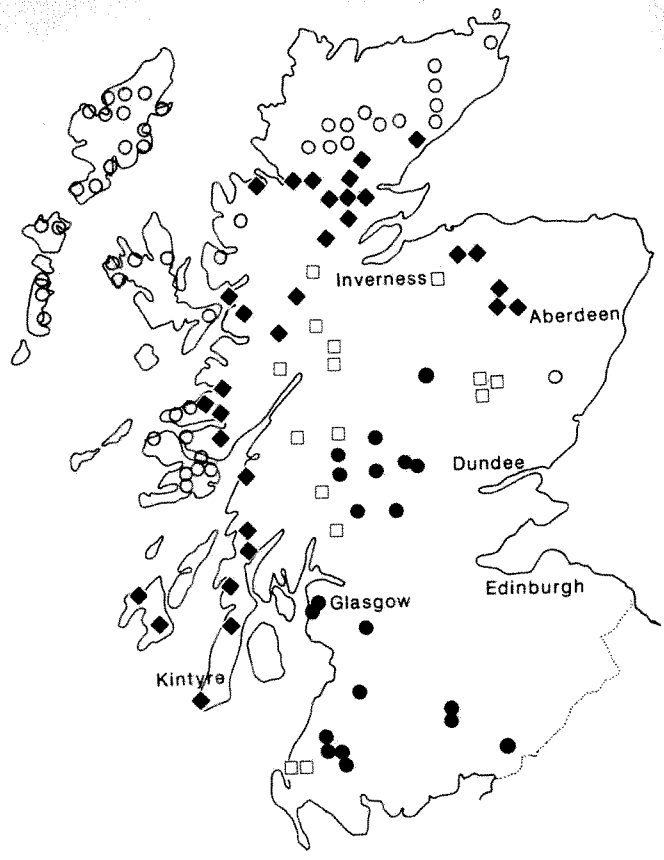

Fig. 1 Modelled wet- and dry-deposited acidity from S, N and Cl species in Scotland (kg H^+ ha^{-1} yr^{-1}). Symbols are: ○, ≤0.6; ◆, >0.6–0.8; □, >0.8–1.0; ●, >1.

The total acid deposition rate in the trajectory model decreased by more than a factor of three across Scotland, from a maximum of >1 kg H^+ ha^{-1} yr^{-1} in south Scotland to a minimum of <0.6 kg H^+ ha^{-1} yr^{-1} in the Outer Hebrides (Fig. 1). Although the prevailing winds throughout Scotland are dominated by winds from the north-westerly through to south-westerly sectors, much of the wet- and dry-deposited acidity in the model is associated with winds and rain from the easterly through to southerly sectors. This reflects the important contribution to deposited acidity from emission sources in England and in the rest of Europe.

Most peats in the areas where acid deposition was >0.8 kg H^+ ha^{-1} yr^{-1} had low *p*H values ($\leq$*p*H 3, Fig. 2) and low base saturation ($\leq$10%, Fig. 3). The correlation coefficients (r^2) for peat *p*H-total acid deposition and for base saturation-total acid deposition were significant, at $p < 0.02$ ($r^2 = 0.051$) for the former and $p < 0.001$ ($r^2 = 0.278$) for the latter.

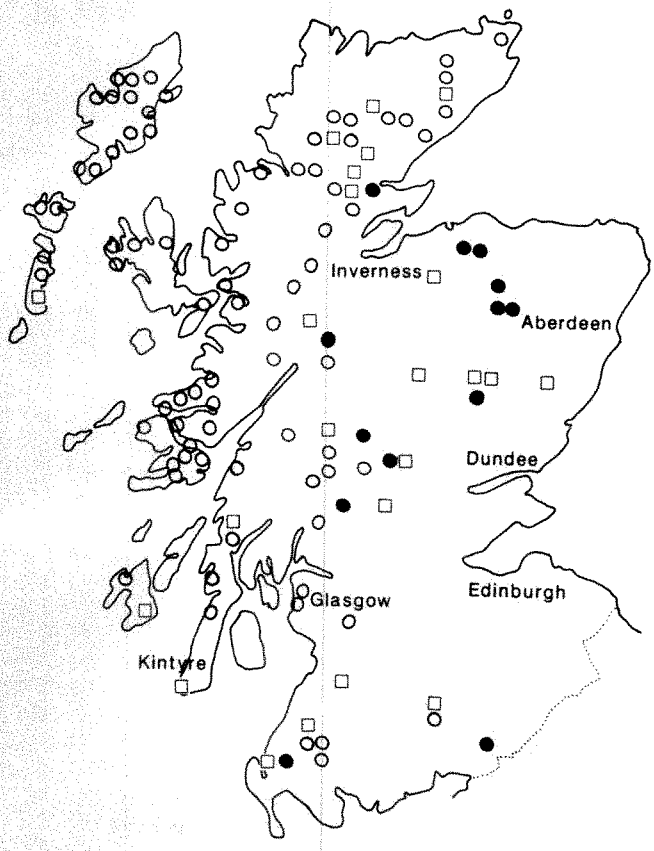

Fig. 2 The pH ($CaCl_2$) of peats in Scotland. ●, ≤2.8 (mean pH of all sites in this group analysed was 2.75); □, >2.8–3.0 (mean pH 2.94); ○, >3.0 (mean pH 3.35).

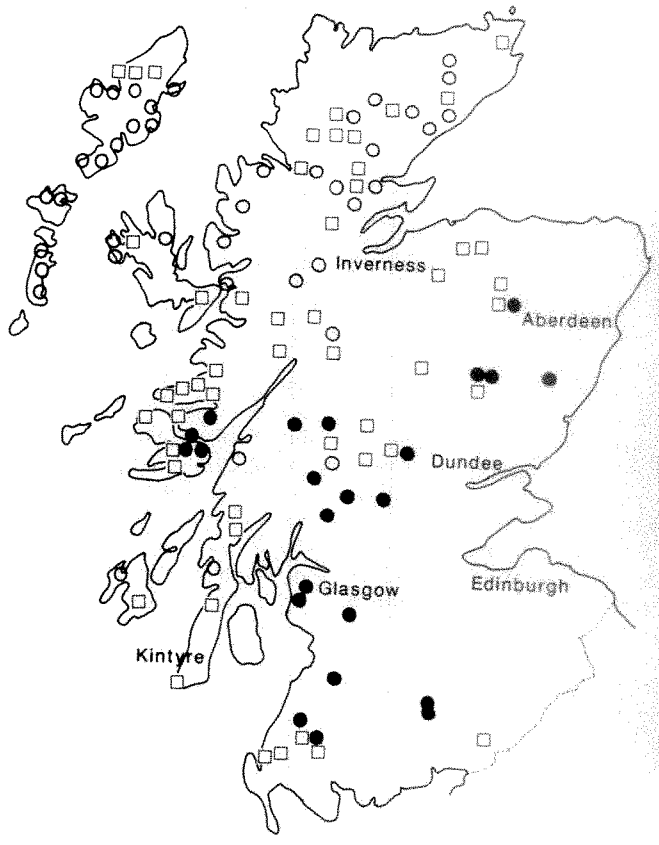

Fig. 3 Percentage base saturation in peats in Scotland. ●, ≤10% (mean % base saturation 6.4); □, >10%–20% (mean % base saturation 15.6); ○, >20% (mean % base saturation 25.1).

Peats were most acidic (pH ≤ 2.8) between Glasgow and Inverness. Acid deposition, however, was greatest in the south, but the number of acid peats sampled here was lower because the peat is less extensive in this area. Land use and management, and position of the peats sampled on a hill site, influence the chemistry of the peat and contribute to the variability in the data observed. Some acid peats (between pH 2.8 and 3.0) were also found on Kintyre and north of Inverness. The spatial distribution of acidifying emissions shows that these pockets of high peat acidity coincided with pockets of SO_2 and NO_x emissions greater than those in surrounding areas[8].

Acid deposition and low base-saturation distributions (Figs 1 and 3) show very good agreement. Low base saturation did not correlate with other variables, such as altitude or rainfall amount. 70% of all peats sampled with a base saturation of <10% came from areas where the modelled wet- and dry-deposited acidity was $>0.8\ kg\ H^+\ ha^{-1}\ yr^{-1}$. On the other hand, 60% of all peats with a base saturation greater than 20% were collected from areas where the deposited acidity was $<0.6\ kg\ H^+\ ha^{-1}\ yr^{-1}$.

The distribution of acid peats and low base saturation of peats in Scotland also correlates well with the recent loss of acid-sensitive lichens. Some lichens, particularly *Lobaria pulmonaria*, are sensitive to low levels of air pollution, primarily SO_2. Distribution maps of *Lobaria pulmonaria* showed that, since 1960, it has disappeared from sites in eastern Scotland, around Edinburgh and Glasgow and also at two sites north of Inverness[9].

As emissions of acid-producing pollutants are declining in many European countries, it is of interest to predict how long it will take for acidified soils to become less acid. A simulation experiment on an accelerated timescale suggests that a decrease in peat acidity should be noticed in a relatively short time period—years rather than decades[3]. Assuming a precipitation pH of 5, extrapolation of published results[3] of simulation experiments showed that a peat now having a pH of 2.8 should decrease in acidity by 0.34 pH units within 10 years, assuming a rainfall of 2,000 mm. After 100 years a decrease in acidity of 0.53 pH units can be expected. The present difference in peat acidity between the south and east of Scotland and the north-west of Scotland is 0.55 pH units (Fig. 2). This suggests that simulated rain experiments yield realistic values for possible pH changes occurring.

The significant correlation between peat acidity or base saturation and total acid deposition gives strong evidence for acid deposition having caused further acidification of peats in Scotland over and above natural levels. As emissions of acid-producing pollutants are declining in many European countries, recovery should become evident in a few decades.

The authors are indebted to the UK Department of the Environment for financial support for this work, and to Dr M. N. Court for assistance with statistics.

Female transfer and inbreeding avoidance in social mammals

T. H. Clutton-Brock

Large Animal Research Group, Department of Zoology, Cambridge CB2 3EJ, UK

In most social mammals, males leave their natal group to breed in other groups whereas females commonly remain in the same group throughout their lives[1]. In a few species however, females usually transfer between groups during adolescence[1]. The functional significance of sex differences in dispersal and their connection, if any, to the avoidance of inbreeding is disputed[2–7]. Here I show that in polygynous mammals where females commonly remain to breed in their natal group, their average age at first conception typically exceeds the average period of residence of adult males in breeding groups. In contrast, where females usually transfer to breed in other groups, the average residence of breeding males or of resident male kin groups typically exceeds the average age of females at first conception. These results support the suggestion that female mammals commonly transfer to avoid inbreeding with their father or other close relatives, although female dispersal may also occur for other reasons[8,9].

Most polygynous, group-living mammals can be classified into three groups on the basis of dispersal. In the majority of species, most males emigrate from their natal group at or shortly after puberty and transfer to other breeding groups, either immediately or at some later stage of their lifespan[1]. Although female emigration is not uncommon in some of these species and female groups may subdivide and occasionally coalesce[3], female transfer into established breeding groups is unusual. Second, in a small number of species females habitually transfer to other breeding groups during adolescence, whereas males commonly remain in their natal group[10–15]. Finally, in a few species that live in uni-male harem groups, both sexes usually disperse from their natal group at adolescence to breed in other groups[16–19].

Male-biased dispersal may predominate in polygynous mammals because adolescent males are commonly ejected from their natal group by resident males[2,3], because the potential benefits of dispersal are usually higher for males than females[20–22] and because the costs of dispersal are generally higher for females because of their lower age at first breeding[7], their more stringent energetic requirements[5,23], and their dependence on coalitions with relatives[24]. Where the majority of males disperse at adolescence, females will seldom need to disperse to avoid inbreeding. So why do females usually disperse in some species? One possible explanation is that females habitually transfer during adolescence in species where the effective breeding lifespans of males within particular groups commonly exceed the age of females at first conception[1,4,21] and where females would risk inbreeding with their father or other close relatives if they remained in their natal group. If so, predominant female dispersal should be associated with male residence in breeding groups that usually exceeds the age of females at first breeding, whereas in species where females remain in their natal group, male residence should usually be shorter than the age at which females breed for the first time.

To test this prediction, I extracted all available estimates of the mean age of females at first conception and of the mean residence of breeding males in particular groups or breeding territories for social, polygynous mammals from the literature. Where several related males defend access to female groups, I used the minimum residence of male kin groups. For one species (grey kangaroos) where a single male is responsible for most matings, I used the average period for which males held alpha rank. The eventual sample included eighteen species where males habitually transfer from their natal group and females usually remain there (Table 1) and nine species where females commonly transfer from their natal group to breed elsewhere (Table 2). The sample of male-dispersing species included ten usually found in uni-male harems (which may include more

For mean male residence: R, residence; α, tenure of α rank. Field data were used to estimate the age of females at first conception wherever possible supplemented by data from ref. 44. Average male residence was the estimated duration of reproductive activity in males within a particular group. In the majority of species, this was equivalent to mean residence per group in non-natal breeding groups but for grey kangaroos I have used the mean tenure of alpha rank and for red deer the average breeding lifespan.

Table 2 Social mammals where female transfer predominates or where both sexes usually transfer

In four species, groups of related males defend access to groups or communities of females. The average residence of male kin groups is unknown in all cases, but take-overs are rare and the average tenure of male groups is evidently long. In one species (hamadryas baboons) females leave their natal units but remain within a larger social unit, consisting of several harems, often belonging to related males.

* Also, H. Kummer, personal communication; † A. H. Harcourt, personal communication; ‡ R. Rudran (unpublished).

than one adult male but where one is responsible for most of all mating) and eight usually found in multi-male, multi-female groups (where more than one mate is involved in breeding). The sample of female dispersing species included four species normally found in uni-male harem groups and four species where a resident kin group of males defends breeding access to a female group. Two further species, black spider monkeys *Ateles paniscus* and woolly monkeys *Lagothrix lagothricha*, may also have breeding systems of this kind but their pattern of dispersal is not yet known[25,26].

In all but one of the eighteen species where females typically remain in their natal group and males usually transfer to breed in other groups, the average age of females at first breeding exceeds the average residence of males in breeding groups (see Table 1). In contrast, in all nine species where females habitually transfer from their natal group, the average residence of breeding males is longer than the age at which females begin to breed (see Table 2). The residence of male kin groups is not known for hunting dogs, red colobus, chimpanzees and bonobos, but take-overs by extra-group males are evidently unusual and it is clear that the average residence of kin groups typically exceeds the age of females at first conception. There is an interesting contrast between these species and lions (see Table 1), where groups of related males also defend breeding access to female prides but take-overs are frequent, male residences are short (average 26 months) and females rarely disperse[24].

The distribution of dispersal thus suggests that where males can effectively defend mating access to feeding territories or to female groups for periods longer than the age of females at first breeding, females may disperse to avoid mating with close relatives. Where male dispersal at adolescence is associated with long male residence (as in gorillas) both sexes are likely to disperse from natal groups. The association between female dispersal and long male tenure does not indicate that females never disperse for other reasons: in at least two social primates, females commonly disperse in circumstances where close inbreeding is unlikely[8,9]. Nor does it indicate that females never risk inbreeding with their fathers or brothers. In some species where females remain in their natal group, the difference between the average duration of male residence and the average age of females at first breeding is small (see Table 1) and a proportion of females will reach breeding age while their father is still active in their group[31]. Under these circumstances, recent evidence suggests that breeding males sometimes disperse or avoid mating with their daughters[5,24,27] or females may disperse[19], attempt to mate with extra-group males[24] or delay conception[28].

I am grateful to Ann Pusey, Jim Moore, Sandy Harcourt, Paul Harvey, Dafila Scott, Phyllis Lee and Mariko Hiraiwa-Hasegawa for comments on the manuscript and to Rudi Rudran and Dan Rubenstein for access to unpublished data.

Pointillistic mixing of interference colours in cryptic tiger beetles

Thomas D. Schultz & Gary D. Bernard*

In insects and other animals, interference colours usually serve as conspicuous visual signals[1-4]. The colours of tiger beetles also originate by interference of multiple reflections[5,6], yet many species exhibit dorsal colorations that appear pigmentary and inconspicuous (cryptic) against soil backgrounds. These dull colours, however, are actually additive mixtures of different interference colours that blend when viewed with the naked eye. This same principle of partitive mixing is used in colour television, printing and the pointillist painting style of neo-impressionist artists[7]. We report here on the first demonstration of interference colours mixing partitively to produce animal camouflage.

Ultrastructural studies show that tiger beetle colours originate from a series of thin cuticular layers near the outer surface of the integument[5]. These layers function optically as a multilayered interference filter. The layers lie directly above a thicker melanized region and conform to a surface microsculpture consisting of alveoli (hexagonal pits) that measure 13 μm across (Fig. 1). The reflectance spectrum depends on the optical thicknesses of the layers and the angles of illumination and observation[8].

We examined the elytra (wing covers) from two colour morphs of the tiger beetle *Cicindela oregona* to determine how interference reflections produced their cryptic colorations. As in many cicindelids[9,10], the elytral coloration of *C. oregona* varies geographically and matches the local soil colour[11]. The morphs exhibited brown or black elytra that appeared pigmentary to the unaided eye. When viewed through an incident-light microscope, however, the alveolar basins and ridges produced a mosaic of coloured reflections that changed with viewing angle. Moreover, discrete patches of alveoli (40-80 μm across) reflected interference colours different from those of the surrounding alveoli.

To compare colours at the macro- and microscopic levels, we measured reflectance spectra for small fields of uniform colour and larger fields that contained the different colour patches. Reflectance spectra from each colour morph were created by mounting specimens of *C. oregona* on the universal stage of an incident-light microspectrophotometer, focusing on an area representative of the elytral colour, and measuring the reflectance with monochromatic flashes at 10 nm intervals[12].

The brown morph exhibited circular patches of blue-green

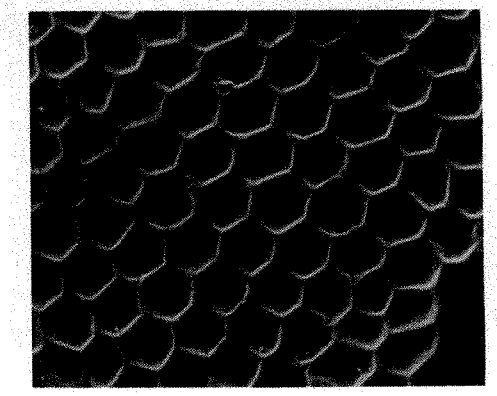

Fig. 1 Scanning electron micrograph of the elytral surface of *Cicindela oregona*. The microsculpture consists of small hexagonal alveoli that measure 13 μm across (magnification ×600).

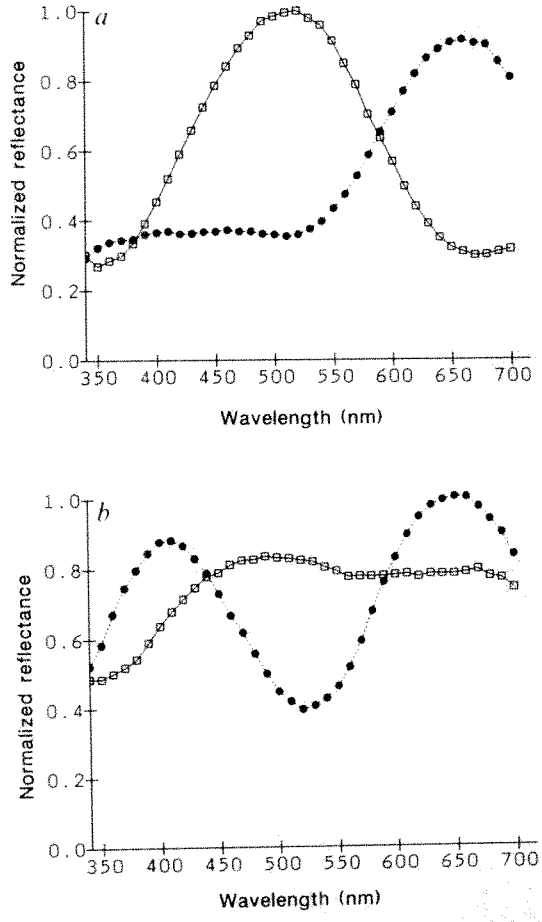

Fig. 2 Normalized reflectance spectra for adjacent microscopic colour patches on the elytra of *Cicindela oregona* measured under high power through a ×40/0.75 objective. Reflectances were measured for patches 30-40 μm in diameter containing 5-8 alveoli of the same colour. The brown morph (*a*) contained blue-green patches (—⊟—) embedded in a red field (···●···). The black morph (*b*) exhibited irregular magenta patches (···●···) surrounded by dull green areas (—⊟—). The microspectrophotometer was based on a Leitz Ortholux microscope with MPV Pol-Opak illuminator, ×8/0.18P or Nikon CF Fluor ×20/0.75 objectives, and Zeiss UV-projective coupled to a Hammamatsu R928 photomultiplier. The aperture stop of the Epi-illuminator was reduced to near minimum, and the incident angle was made as oblique as possible. The instrumental baseline was calibrated with a National Bureau of Standards SRM-2003D spectral reflectance standard.

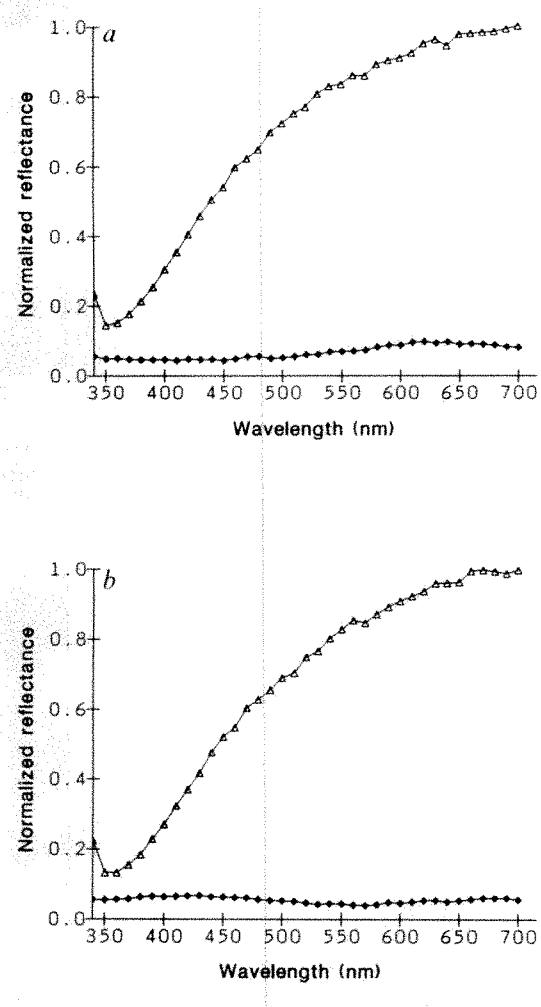

Fig. 3 Normalized reflectance spectra of coloured and white elytral areas from the same two morphs of *C. oregona* but measured under low power through a ×8/0.18 objective. Reflectances were measured, for fields (300 μm in diameter) containing ~530 alveoli, in both the coloured and white areas of the brown (*a*) and black (*b*) elytra. Fields in the coloured area contained 7–8 microscopic colour patches described in Fig. 2. Reflectances of the coloured areas (—◆—) are plotted with the same normalization constant as the white areas (—△—) to illustrate the desaturation and low brightness of the mixed colours.

alveoli surrounded by a red field (Fig. 2*a*). In the black morph, irregular patches of magenta interference colours were surrounded by dull green alveoli that reflected both green and magenta colours (Fig. 2*b*). The alveoli of pure magenta patches produced two prominent reflectance peaks at 660 nm and 400 nm.

Spectra produced by partitive mixing of the microscopic colour patches were measured by decreasing the magnification to include eight colour patches and their surrounding field. The resulting spectra were low in intensity and saturation when compared to an adjacent white elytral spot. The brown morph showed a broad, and slightly elevated reflectance between 500 and 750 nm due to the summation of green and red reflections (Fig. 3*a*). In the black elytra, the summation of green and magenta areas produced a relatively flat, unsaturated reflectance spectrum (Fig. 3*b*).

In tiger beetles such as *C. oregona*, reflecting layers may vary in periodicity, resulting in small clusters of alveoli that reflect different wavelengths[5]. These colour patches are too small to be resolved by the unaided eye and spatially fuse to produce an additive colour mixture[13]. Partitive mixing of different spectral combinations produces different cryptic colour morphs of *C. oregona*.

In addition, the surface microsculpture affects the intensity and wavelength content of these mixed colours. The pitted elytral surface scatters the reflected light over a wide range of angles, thereby reducing the amount of light measured by the modest collecting angle of the microscope. Similarly, much of the scattered light escapes the even smaller collecting angle of the observer's eye, causing the colours to appear dark. The reflectance spectrum is affected also by the angle of the reflecting surface relative to incident light[8]. Shorter wavelengths reflected from the angled walls of the alveoli additively mix with those reflected from the ridges and basins, reducing the purity of the colour.

Many cryptic colorations of animals are produced through partitive mixing, but most involve pigments[14,15]. However, in tiger beetles and other Coleoptera[16,17], partitive mixing of different interference colours and scattering by the surface microsculpture produce broad-band reflectance spectra that match background colours and serve as camouflage.

We thank J. C. Schultz, N. F. Hadley and R. Wehner for reviewing drafts of this manuscript.

Substitution at residue 227 of H–2 class I molecules abrogates recognition by CD8-dependent, but not CD8-independent, cytotoxic T lymphocytes

The CD8 (Lyt 2) molecule is a phenotypic marker for T lymphocytes that recognize and react with major histocompatibility complex (MHC) class I molecules. Antibody blocking experiments[1,2] and gene transfection studies[3,4] indicate that CD8 binds to a determinant on MHC class I molecules on the target cells, facilitating interaction between effector T lymphocytes and the target cell. The CD8 molecule may also be involved in transmembrane signalling during T-cell activation[5,6]. The existence of CD8⁻ cytotoxic T lymphocytes (CTL)[7] and class I-reactive CTL that are not inhibited by antibody to CD8 suggests that at least some CTL do not require the CD8 molecule to interact with and lyse target cells. We have recently demonstrated that cells transfected with

an *H-2D*^{d} gene that carries a mutation at residue 227 are not killed by primary CTL[8]. Here we show that although this mutation abrogates recognition by primary CTL, it does not affect recognition by CD8-independent CTL, suggesting that residue 227 of class I molecules might contribute to a determinant that is the ligand of the CD8 molecule.

We first described a somatic cell mutant isolated by immunoselection that expressed a variant H-2D^d molecule which was not killed by alloreactive anti-H-2D^d CTL[9]. This cell line had been isolated because of its failure to express a serological determinant expressed in the α3 domain. Recently[8] we identified the mutation in the α3 domain of the H-2D^d molecule as a Glu → Lys substitution at residue 227. This change was reproduced in a cloned *H-2D*^{d} gene by oligonucleotide-directed mutagenesis. Cells transfected with this mutant gene expressed all the serological epitopes on the H-2D^d α1/α2 domains but were not killed by anti-H-2D^d CTL populations generated *in vitro* in primary responses. This was not apparently a result of the destruction of the conformation of the H-2D^d molecule, because the mutant stimulated an anti-H-2D^d reactive IL-2-secreting T-cell hybridoma as efficiently as the wild-type H-2D^d molecule.

We first determined whether this mutation in other class I genes could abrogate CTL recognition by the creation of hybrid genes through exon shuffling[10,11]. Hybrid genes comprised the 5′ region and exons 1-3 (α1/α2 domains) from the *H-2K*^{b} gene ligated to exons 4-8 (α3 domain, transmembrane and cytoplasmic regions) of the *H-2D*^{d} gene (Fig. 1). One gene, referred to as *H-2K*^{b}/*D*^{d} Glu, had glutamic acid at position 227 (as does wild-type *H-2D*^{d}), whereas the other gene, *H-2K*^{b}/*D*^{d} Lys contained a mutation that leads to substitution with lysine at position 227. Both of these genes were transfected into the cell line R8.161, an H-2^{b-} variant isolated from the R8 (H-2^b/H-2^d) cell line. Cells expressing these genes were isolated and serological expression of H-2K^b α1/α2 epitopes, defined by a panel of antibodies to H-2K^b, was confirmed by flow-microfluorimetry analysis (Fig. 2). The reactivity of antibodies to the α1/α2 domains of H-2K^b with the transfectants expressing either the *H-2K*^{b}/*D*^{d} Glu or *H-2K*^{b}/*D*^{d} Lys genes was identical, indicating that this substitution in the α3 domain did not significantly affect the conformation of the α1/α2 region of H-2K^b. These cells were also used as targets for anti-H-2K^b

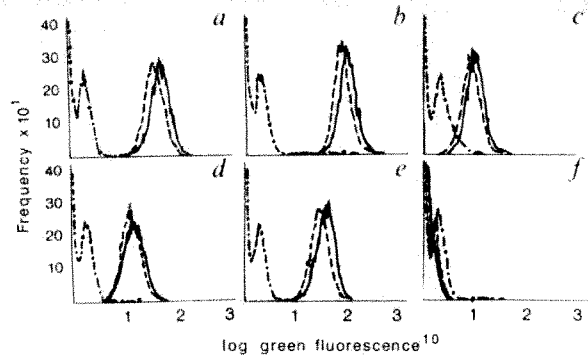

Fig. 2 Flow-microfluorometry analysis of *H-2K*^{b} expression on R8.161 and transfected cell lines.
Methods. Cells were analysed for serological expression of *H-2K*^{b} epitopes by incubating 10^6 cells with 100 µl H-2K^b antibodies at an optimal dilution on ice for 30 min. The cells were washed and then incubated for a further 30 min with fluorescein isothiocyanate-conjugated goat anti-mouse immunoglobulin. After staining, the cells were washed and the fluorescence of 10,000 viable cells measured on an EPICS 752B. The fluorescence profiles for R8.161 H-2K^b Glu (----), R8.161 H-2K^b Lys (——) and R8.161 (-·--·) are shown. The determinants recognized by the EH144 (*a*) and B8-24-3 (*b*) antibodies have been mapped to the α1 domain, antibodies 5F1 (*c*) and 28-13-3 (*d*) to the α2 domain; residues from both α1 and α2 contribute to the determinant recognized by the K9-178 (*e*) antibody[11,16]. Antibody 128-3-3 (*f*) is specific for the H-2K^{bm10} mutation and is used here as a non-reactive control.

CTL generated in a primary *in vitro* response (B10.D2) (ddd) anti-B10 (bbb). These CTL lysed cells expressing the *H-2K*^{b}/*D*^{d} Glu gene product (Fig. 3*a*), but did not lyse transfectants expressing the product of the *H-2K*^{b}/*D*^{d} Lys gene (Fig. 3*d*). This reactivity was similar to that of anti-H-2D^d CTL with cells expressing the mutant or wild-type *H-2D*^{d} gene[8]. Adding antibody to CD8 inhibited the reactivity of the CTL for cells expressing the *H-2K*^{b}/*D*^{d} Glu gene product (Fig. 3*a*). To find out the role of CD8 in the lysis of these cells, we generated CTL that were less readily inhibited by anti-CD8 antibody by priming B10.D2 mice with EL4 cells, followed one week later by restimu-

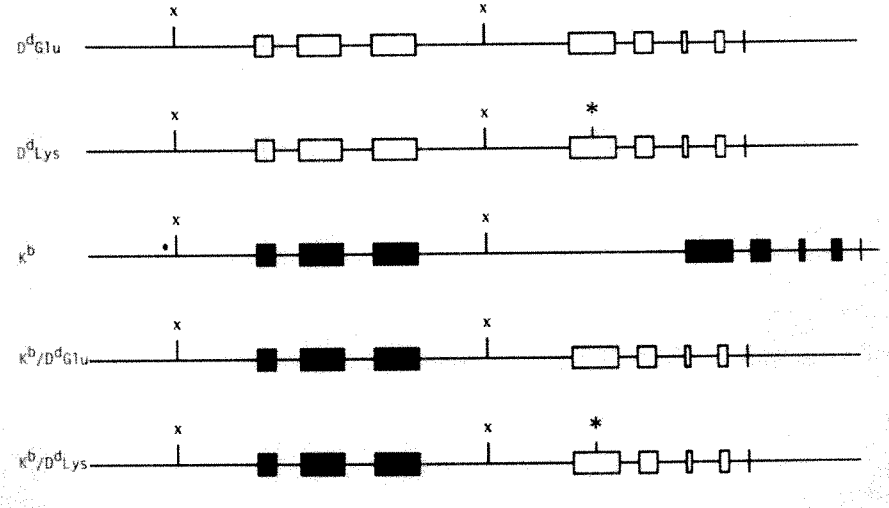

Fig. 1 Construction of hybrid genes used in this study. The *H-2D*^{d} gene used here actually contains a 700-base pair deletion from the *Kpn*I to *Hpa*I site in the third intervening sequence of the *H-2D*^{d} gene isolated by Margulies *et al.*[14]. This deletion, which was produced during the religation of the 2.1-kilobase (kb) *Hpa*I fragment containing exons 4-8 which had been subcloned into M13mp19 for site-directed mutagenesis, did not affect expression of the gene[8]. The mutation at residue 227 was produced by oligonucleotide-directed mutagenesis as previously described[8]. The *H-2K*^{b}/*D*^{d} Glu gene was produced by replacement of the 1.9-kb *Xba*I fragment encoding exons 1-3 of the *H-2D*^{d} gene with a similar fragment from the *H-2K*^{b} gene. Digestion with *Pvu*II ensured that exons 1-3 were inserted in the correct orientation. The hybrid genes were cloned into the pSV2Neo plasmid. Plasmid DNA containing these genes was introduced into R8.161 by electroporation[15]. After 48 hours incubation at 37 °C, G418 antibiotic (Gibco) was added to a concentration of 1.0 mg ml^{-1}. *X* denotes the location of the *Xba*I sites that flank exons 1-3 of both *H-2D*^{d} and *H-2K*^{b} and * denotes the location of the point mutation encoding lysine at residue 227 in the α3 domain.

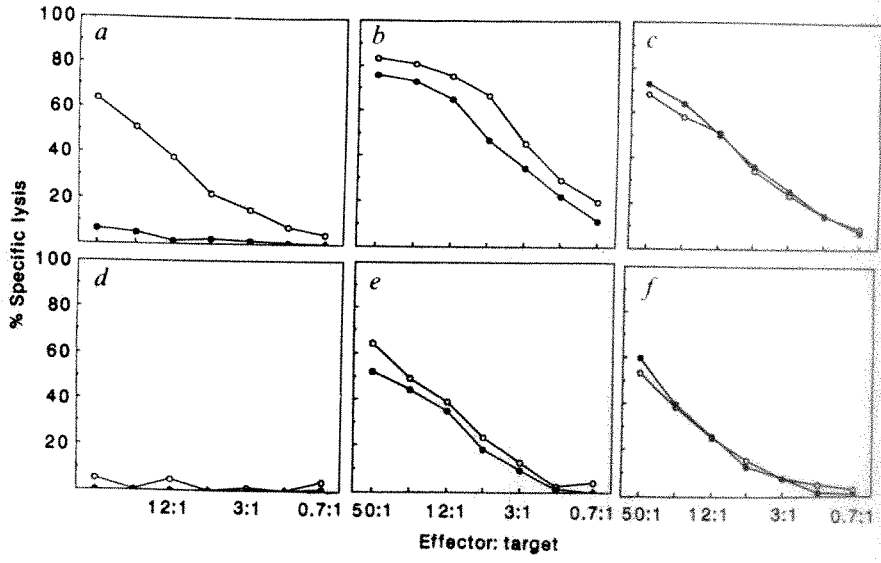

Fig. 3 Reactivity of primary and secondary anti-H-2K^b CTL for the R8.161 cells transfected with the *H-2K^{b}D^d* hybrid genes. The target cells were R8.161 H-2K^b/D^d Glu (*a*–*c*) and R8.161 H-2K^b/D^d Lys (*d*–*f*). The CTL populations were primary anti-H-2K^b (*a* and *d*), secondary anti-H-2K^b generated in the presence of anti-CD8 antibody (*b* and *e*) and primary anti-H-2^d (K^d, D^d, L^d) (*c* and *f*). The assay for CTL reactivity was performed either in the absence (○—○) or the presence (●—●) of an antibody to CD8.2 83-12-5. The inclusion of the anti H-2K^d/D^d CTL population (AKR anti B10.D2; panels *c* and *f*) demonstrated that both types of transfected cells were readily killed by CTL reactive with H-2^d molecules present on transfected and on non-transfected cells. The failure of the anti-CD8.2 antibody to inhibit these CTL, isolated from AKR mice which are CD8.1, established that the effect of this antibody on CTL populations isolated from B10.D2 was specific for the CD8 molecule.

Methods. The primary CTL were generated by a 5-day culture of B10.D2 spleen cells with irradiated (2,500 rad) B10 spleen cells, as previously described[17,18]. 4×10^6 splenic responder cells were mixed with 4×10^6 stimulator cells in a final volume of 2 ml culture medium which contained selected fetal bovine serum (FBS) and 10% lectin-free concanavalin A-induced supernatant, and incubated at 37 °C for 5–6 days. The secondary CTL were generated by priming B10.D2 mice with irradiated (5,000 rad) EL4 tumour cells injected intraperitoneally one week before stimulation of the spleen cells *in vitro* in the presence of CD8.2 (83-12-5) antibody. The reactivity of CTL was assessed by ^{51}Cr release, using 5×10^3 labelled target cells in a final volume of 200 μl. Effector and target cells were incubated together in 96-well U-bottom plates for 4–6 h at 37 °C. Culture supernatants were collected and specific lysis determined as specific release (%): 100 × (experimental release) − (spontaneous release)/(maximum release) − (spontaneous release). The experimental release represents the release of ^{51}Cr from target cells incubated with effector cells. The spontaneous lysis is the release in the absence of effector cells and the maximum release is that released by the target cells in the presence of 0.05 M HCl.

lation of the spleen cells *in vitro* for 5 days in the presence of antibody to CD8. These secondary CTL killed not only the *H-2K^b/D^d* Glu transfectant (Fig. 3*b*), but also the *H-2K^b/D^d* Lys transfectant (Fig. 3*e*). The level of lysis of the *H-2K^b/D^d* Lys transfectant was slightly less than that of the *H-2K^b/D^d* Glu transfectant, but a comparable difference was also found in the lysis of the transfectants by anti H-2^d CTL (Fig. 3*c* and *f*). Although the response of the secondary anti-H-2K^b CTL population was less susceptible than the primary anti-H-2K^b CTL to the addition of antibody to CD8, lysis of the *H-2K^b/D^d* Lys transfectant by the secondary CTL population was partially inhibited by the CD8 antibody (Fig. 3*e*). This effect could be due to the anti-CD8 antibody interfering either with the reaction of CD8 and other class I molecules on the surface of the transfected cells or with events such as receptor redistribution (capping) or signal transduction by the CD8 molecule.

Our interpretation of these findings is that substitution of lysine for glutamic acid at residue 227 destroys the determinant on the H-2 class I molecule that is recognized by the CD8 molecule on CTL. Although we think it is more likely that residue 227 contributes directly to the determinant recognized by CD8, we cannot rule out the possibility that substitution at residue 227 might indirectly alter the determinant bound by CD8. Another possibility is that the mutation at residue 227 could affect the conformation of the $\alpha 1/\alpha 2$ determinants, so that only high-affinity CD8-independent CTL can recognize the molecule. If there were such a major conformational change, however, then at least some of the anti H-2K^b $\alpha 1/\alpha 2$ monoclonal antibodies would probably have reacted differently with the *H-2K^b/D^d* Lys transfectant. As shown here, the antibodies reacted identically with both *H-2K^b/D^d* transfectants.

The three-dimensional structure of an HLA class I molecule has recently been determined[12,13] and indicates that residues from the $\alpha 1$ and $\alpha 2$ domains could form a binding site for antigenic peptides between two α-helices. Residue 227 in the $\alpha 3$ domain is located on the surface of the molecule, is accessible to solvent and is at least 50 Å away from the $\alpha 1/\alpha 2$ peptide-binding cleft (M. A. Saper and D. Wiley, personal communication), suggesting that substitution at position 227 is unlikely to affect CTL determinants in the $\alpha 1/\alpha 2$ domains dramatically. Another implication of our results is that, should CD8 bind to a conserved determinant which includes or is influenced by residue 227, then for CD8-dependent CTL, this interaction must be with the same class I molecule as is interacting with the T-cell receptor α/β complex. This is because the reactivity of primary CD8-dependent anti-H-2K^b CTL was abrogated by the mutation, even though the transfected cells expressed other class I molecules such as H-2K^d, H-2D^d and H-2L^d.

This work was supported by grants from the National Institutes of Health and a grant from the Lucille P. Markey Charitable trust. J.A.B. is a Gould Foundation Faculty Scholar. We thank John Hartley for expert technical assistance with the flow microfluorometry and Ms Rosina Passela for the preparation of this manuscript.

Duchenne muscular dystrophy gene product is not identical in muscle and brain

Uri Nudel, Dorit Zuk, Paz Einat, Elisha Zeelon*, Zehava Levy, Sara Neuman & David Yaffe

Department of Cell Biology, The Weizmann Institute of Science, Rehovot 76100, Israel
* Biotechnology General, Kiryat Weizmann, Ness Ziona, Israel

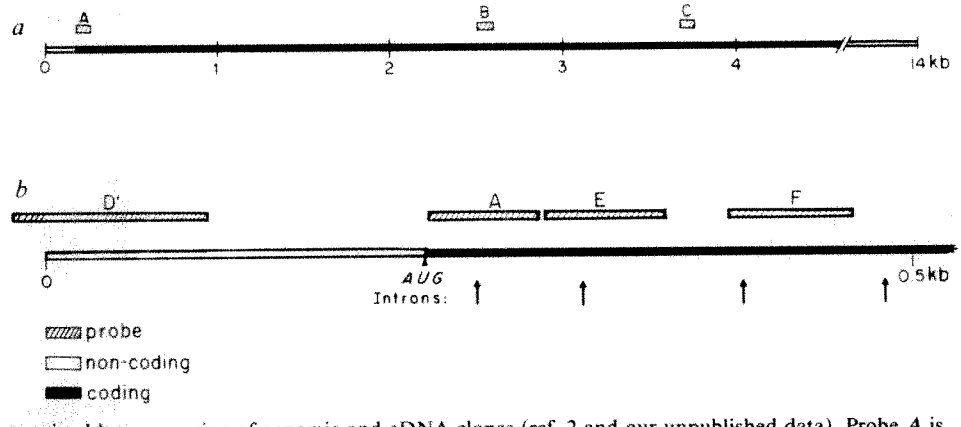
Duchenne muscular dystrophy (DMD) is an X-linked recessive disorder resulting in progressive degeneration of the muscle. It affects about 1 in 3,500 male children. Becker's muscular dystrophy is a less severe disease allelic to DMD. Some 30% of DMD patients suffer from various degrees of mental retardation (see ref. 1 for review). The giant DMD gene spans about 2,000 kilobases and codes for a 14-kilobase messenger RNA and a protein of molecular weight 427,000 (ref. 2). DMD mRNA is most abundant in skeletal and cardiac muscle and less so in smooth muscle[3–5]. We reported that the expression of the gene is developmentally regulated during the differentiation of primary muscle cultures and in myogenic cell lines in a way similar to the expression of muscle-specific genes such as myosin light chain 2 and skeletal muscle actin[5]. Similar results have been obtained with human primary myogenic cells[6]. Significant levels of DMD mRNA are found in brain tissue[5,7]. Here we show that the transcript of the DMD gene and the amino terminal of the encoded protein differ in brain and muscle. The 5′ ends of these mRNA species are derived from different exons. The results suggest that the two mRNA types are transcribed from different promoters.

To investigate whether the DMD gene product is identical in muscle and brain, we prepared RNA probes complementary to various parts of the DMD mRNA. These RNA probes are described schematically in Fig. 1*a*. Total RNA preparations from rat skeletal muscle, cardiac muscle, aorta, brain and other tissues were assayed with these probes, using the RNase protection method[8]. Figure 2 shows how probes *B* and *C*, which are complementary to nucleotides 2,502–2,588 and 3,680–3,758 respectively of the reported mouse muscle DMD complementary DNA sequence[4,9], are protected by muscle and brain RNA, whereas probe *A*, which is complementary to the first 22 codons of the muscle mRNA, is protected by muscle mRNA and not by brain mRNA.

These results indicate that the 5′ region of the muscle DMD mRNA contains sequences that are not present in the brain mRNA, so we constructed additional probes complementary to sequences in this region of the muscle DMD mRNA (Fig. 1*b*) and assayed them with muscle and brain RNA preparations. Probe *D′* was derived from a mouse genomic clone and is complementary to a sequence extending from the *Mbo*II site in the 5′ noncoding region of the muscle type mRNA (nucleotide 80) into the 5′ flanking region. A major 112-nucleotide-long fragment of this probe is protected by muscle RNA but not by brain RNA. These results were obtained with both rat and mouse mRNA. As the protected fragment is longer than expected (80 nucleotides), we suggest that the 5′ end of the mRNA is located 32 nucleotides upstream from the position deduced from the published sequences of the cDNA clones[4,9]. This conclusion is supported by primer extension experiments, and is in accordance with the position of a putative ATA box located 30 nucleotides upstream from the proposed major cap site (data not shown). Probes *E* and *F* cover codons 24–47 and 58–81 respectively and are protected by both muscle and brain RNA (Fig. 3; the results obtained with probe *F* are not shown).

On the basis of these results and of the proposed structure of the 5′ region of the DMD gene (Fig. 1*b*), we concluded that the sequence of the exon that constitutes the 5′ end of the muscle type DMD mRNA (deduced from the sequences of the muscle cDNA and genomic clones) is not represented in brain DMD mRNA. This exon contains the 5′ untranslated region and the first 11 codons. The protection of probes *E* and *F* by both brain and muscle mRNA indicates that the brain DMD mRNA contains codons 24–47 and codons 58–81 of the muscle type mRNA.

To determine the exact point of divergence between the muscle and brain DMD mRNAs, we constructed a rat-brain cDNA library using an oligonucleotide primer complementary to nucleotides 554–582 of the muscle DMD mRNA. The library was screened with the probes described in the legend to Fig. 4 and a positive clone was purified, amplified and sequenced. Comparison of the rat brain and mouse muscle DMD cDNAs (Fig. 4) reveals an almost complete identity of the sequences starting at the 5′ end of the muscle second exon (small sequence differences, which are all but one silent, are probably a result of the variability between rat and mouse). But sequences 5′ to that point are completely different. Thus, the divergence point between the muscle and brain DMD mRNA types is at the junction between the first and second exons. This divergence also results in a difference between the amino terminal of the brain and muscle dystrophin proteins. The first eleven amino



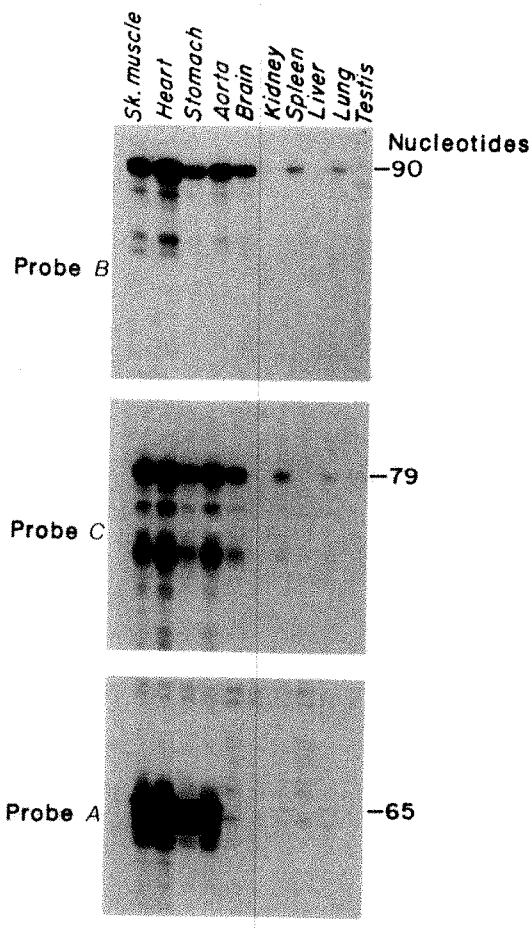


Fig. 1 Schematic representation of the probes used in the RNase protection assay. *a*, The regions of DMD mRNA complementary to probes *A*, *B* and *C*. *b*, The 5′ end of the muscle DMD mRNA and the probes used to analyse this region. The horizontal bar represents the DMD mRNA (blank, noncoding region; solid, coding region). The AUG indicates the putative translation initiation codon. The nucleotide numbering is according to the mouse cDNA sequences reported by Hoffman *et al.*[4] and Koenig *et al.*[9]. Hatched boxes represent regions of mRNA complementary to the probes. Arrows (in *b*) indicate the position of introns as determined by sequencing of genomic and cDNA clones (ref. 2 and our unpublished data). Probe *A* is complementary to nucleotides 221–285 (the putative first 22 codons); probes *B* and *C* are complementary to nucleotides 2,502–2,588 and 3,680–3,758 respectively. Probe *D′* extends from the *Mbo*II site at nucleotide 80 into the 5′ flanking region. Probes *E* and *F* are complementary to nucleotides 289–360 and 395–466 respectively. Probes *A* (pMD12), *C* (pMD51), *E* (pMD61) and *F* (pMD62) were constructed by introducing synthetic oligonucleotides into the vector gemini 3 (Promega). Probe *B* (pMD1), as described previously[5], contains a rat genomic DNA fragment cloned in gemini 3. Probe *D′* (pMD13) contains a mouse genomic DNA fragment cloned in gemini 3. The RNA probes were synthesized using the T7 (probes *A*, *C* and *D′*) or SP6 (probes *B*, *E* and *F*) RNA polymerases.

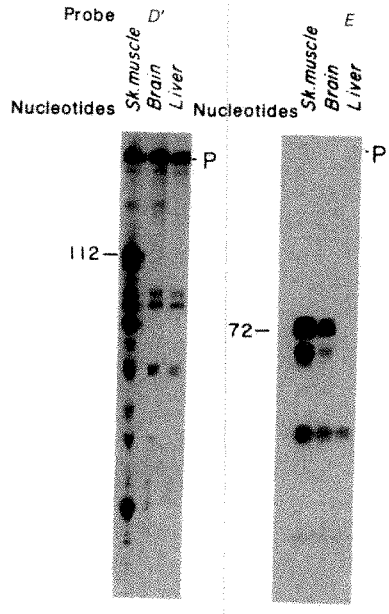

Fig. 3 Differential expression of sequences from the 5′ end of the DMD mRNA in muscle and brain.
Methods. Total RNA (10 μg) from the rat tissues indicated were assayed with probes *D′* and *E* as described in Fig. 2, except that the RNase digestion after the hybridization with probe *D′* was for 1 h at 25 °C. P indicates the position of the undigested probes on the gel, and the numbers indicate the sizes of the main protected fragments. The smaller specific bands are probably caused by unstable regions in the RNA–RNA hybrids.

◀ **Fig. 2** DMD gene expression in various tissues.
Methods. Total RNA was prepared from the tissues indicated using the lithium chloride/urea extraction procedure[11]. The integrity and quantity of all RNA samples were verified by electrophoresis on agarose/formaldehyde gels (not shown). All the RNA samples were extracted from rat tissue, except for testis RNA which was extracted from a mouse. As described previously[5], there is a mismatch between the rat and the mouse sequences at the end of the sequence protecting probe *B*, giving a smaller protected band when mouse RNA is used, as can be seen for testis RNA in the middle panel. The RNA protection assay was as previously described[5], except that hybridization was at 48 °C and 10 μg total RNA were used in each assay. Gels were fluorographed for four days after electrophoresis. *A*, *B* and *C* specify the probe used in each assay. As probes *A* and *C* contain vector sequences and probe *B* includes introns, the protected fragment is shorter than the labelled probe in all cases. The region of the gels containing the protected fragments is shown.

Fig. 4 Comparison of the 5′ end region of the brain and muscle type DMD cDNAs. The rat brain DMD cDNA sequence was aligned with the mouse muscle DMD cDNA sequence. The triangles indicate the exon borders (ref. 2 and our unpublished data). The initiator ATGs of the two cDNAs are underlined. The brain type DMD mRNA contains five additional ATG triplets located upstream from the initiator ATG but they do not fit with the open reading frame of the coding sequences. These ATG triplets may be involved in the regulation of translation of the mRNA[16].
Methods. The brain cDNA library was constructed using polyadenylated RNA from rat brain and an oligonucleotide primer extending from nucleotide 554 to nucleotide 582 of the mouse muscle DMD cDNA[9]. The first and the second strands of the cDNA were synthesized using AMV reverse transcriptase and *E. coli* DNA polymerase respectively. After treatment with T4 DNA polymerase to produce blunt ends, ligation with *Eco*RI site-containing linkers, restriction with *Eco*RI and removal of the primer, the cDNA was cloned into the *Eco*RI site of λGT11. Approximately 50,000 phages were screened using two oligonucleotides homologous to the coding region of the mouse muscle DMD cDNA (nucleotides 318–360 and nucleotides 247–300). A phage that hybridized to both probes was purified and amplified. The 500-bp DNA insert was cloned into the *Eco*RI sites of M13mp19 and pUC19 and sequenced by the Sanger dideoxy termination method[14] and by the Maxam and Gilbert chemical degradation method[15].

acids (Met-Leu-Trp-Trp-Glu-Glu-Val-Glu-Asp-Cys-Tyr) of the muscle protein are replaced by three amino acids (Met-Glu-Asp) in brain dystrophin.

As the second exon is identical in both mRNA types, brain mRNA should also protect a 32-base pair (bp) fragment of probe *A* (Fig. 1), but we were unable to detect such a fragment in our assays (Fig. 2). This might be due to the very low G+C content (28%) of this region of the probe. The 5′ half of the probe has a 45% G+C content, permitting stable hybridization when the entire probe is protected by muscle mRNA. As seen in Fig. 2, we can also detect DMD mRNA in spleen (5–10% of the amount in striated muscle), and smaller amounts are detected in the lung and testis. At the present level of sensitivity of the assay system, DMD mRNA was barely detectable in kidney and was not detectable in liver RNA preparations.

These results show that the DMD gene, which in myogenic cells is developmentally regulated, is also expressed in non-myogenic tissues. Detection of DMD mRNA and protein in non-muscle tissues has also been reported recently by Chelly *et al.*[12] and Hoffman *et al.*[13] respectively. We have found that the DMD gene is also expressed in cultured brain cells (in collaboration with R. Simantov, unpublished results). This observation and the finding that the brain DMD mRNA is not identical to that of the muscle clearly demonstrates that the DMD RNA found in the brain tissue originated from brain cells and not from the smooth muscle of blood vessels. Experiments are currently being carried out to identify the DMD isoforms and the cell types that express the DMD gene in other non-muscle tissues.

Genetic considerations and Southern blot analysis have indicated the existence of only one DMD gene[3,5] Two mechanisms could, separately or together, be responsible for the production of more than one mRNA from a single gene: (1) alternative splicing of an exon or exons from the gene transcript and (2) alternative initiation of transcription from different promoters reviewed in ref. 10). The finding that sequences of the 5′ end of the muscle and brain DMD mRNAs are different indicates that two promoters with different tissue and developmental specificities could be involved in the initiation of transcription to produce the different mRNAs.

Okadaic acid is a polyether derivative of 38-carbon fatty acid[1], and is implicated as the causative agent of diarrhetic shellfish poisoning[2]. It is a potent tumour promoter that is not an activator of protein kinase C (ref. 3), but is a powerful inhibitor of protein phosphatases-1 and -2A (PP1 and PP2A) *in vitro*[4,5]. We report here that okadaic acid rapidly stimulates protein phosphorylation in intact cells, and behaves like a specific protein phosphatase inhibitor in a variety of metabolic processes. Our results indicate that PP1 and PP2A are the dominant protein phosphatases acting on a wide range of phosphoproteins *in vivo*. We also find that okadaic acid mimics the effect of insulin on glucose transport in adipocytes, which suggests that this process is stimulated by a serine/threonine phosphorylation event.

The first insight into the mechanism of action of okadaic acid came from the finding that it enhanced the contraction of skinned smooth muscle fibres, indicating that myosin P-light chain phosphorylation was increased[6]. This appeared to be mediated by inhibition of protein phosphatase(s) as myosin light chain kinase activity was unaffected and a phosphatase from smooth muscle with activity towards isolated myosin P-light chains was inhibited by okadaic acid[7]. The toxin was recently shown to be a potent inhibitor of PP1 and PP2A (refs 4 and 5), which have homologous catalytic subunits[8] and make up two of the four cytosolic serine/threonine-specific protein phosphatase catalytic subunits in mammalian cells[9–11]. PP2B (a calcium/calmodulin-dependent enzyme) was inhibited with much lower potency, whereas PP2C (a magnesium-dependent enzyme) was unaffected[4,5].

Okadaic acid produces marked increases in the phosphorylation states of many proteins in adipocytes and hepatocytes, as judged by increased ^{32}P-labelling (Fig. 1), without changing the specific radioactivity of intracellular ATP or the ATP:ADP ratio (data not shown). Proteins whose phosphorylation increased included polypeptides that comigrated with acetyl-CoA carboxylase and ATP-citrate lyase in adipocyte and hepatocyte cytosol, pyruvate kinase and 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase (PFK2/FBPase) in hepatocyte cytosol, and glycogen phosphorylase and glycogen synthase in the hepatocyte glycogen fraction. The prominent protein of relative molecular mass 32,000 in the hepatic microsomal fraction whose phosphorylation increased markedly in response to okadaic acid is likely to be ribosomal protein S6. Okadaic acid treatment (15 min) stimulated the ^{32}P-labelling of total trichloroacetic acid-insoluble protein in hepatocyte cytosol 2.5-fold, with a half-maximal effect at 200 nM and maximal effect at 1 μM.

The protein kinases which phosphorylate the above-mentioned proteins *in vivo* include cyclic AMP-dependent protein kinase[12], the AMP-activated protein kinase[13], phosphorylase kinase[14], glycogen synthase kinase-3 (ref. 15) and casein kinase-2 (refs 16 and 17). Using glycogen synthase as substrate, okadaic acid at concentrations as high as 5 μM failed to affect the activity of any of these protein kinases, or casein kinase-1 (data not shown). The purified catalytic subunits of PP1 and PP2A were potently inhibited by okadaic acid with 50% inhibitory concentration values of 20 nM and 0.2 nM respectively which are even lower than those reported previously[4,5]. The PP2A catalytic subunit was completely inhibited by 1 nM

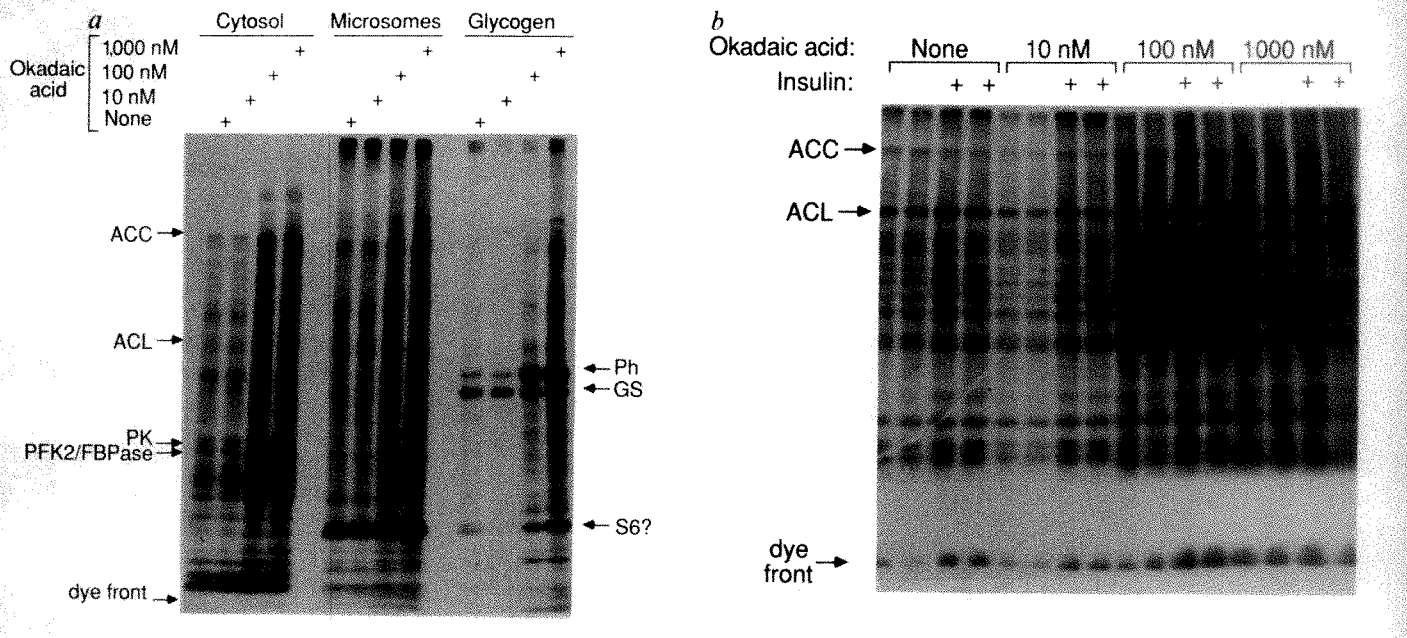

Fig. 1 Effects of okadaic acid on protein phosphorylation in isolated hepatocytes (*a*) and adipocytes (*b*) from fed rats. For adipocytes, incubations were carried out in duplicate in the presence and absence of 0.9 nM insulin. Cells were isolated and prelabelled with [^{32}P]phosphate for 60 min[20,21] before addition of okadaic acid or insulin for 15 min. Okadaic acid was added in 10% dimethylsulphoxide to give a final concentration of dimethylsulphoxide of 0.25% (v/v) in all incubations. Cells were collected and homogenized, and post-mitochondrial supernatants were prepared by centrifugation (10,000*g* for 15 min at 4 °C). For hepatocytes only, the post-mitochondrial supernatant was separated into cytosol, glycogen and microsomal fractions by centrifugation (100,000*g* for 60 min at 4 °C). The supernatants were removed (cytosol fraction), and the upper microsomal pellet was resuspended in homogenization buffer separately from the lower glycogen pellet. Fractions were analysed at equal protein loadings by electrophoresis in 5–15% gradient polyacrylamide gels. Gels were dried and autoradiographed at −70 °C using Amersham Hyperfilm-MP in Kodak X-omatic intensifying cassettes. The migration of marker proteins is shown, using the abbreviations: ACC, acetyl CoA carboxylase; ACL, ATP-citrate lyase; PK, pyruvate kinase; PFK2/FBPase, 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase; Ph, glycogen phosphorylase; GS, glycogen synthase; S6, ribosomal protein S6. The specific radioactivity of cellular ATP and ATP/ADP ratios were determined by HPLC (ref. 21).

okadaic acid, a concentration comparable with that of the phosphatase subunit in the assay.

As a number of the proteins in adipocytes and hepatocytes whose phosphorylation was increased by okadaic acid were enzymes of glucose and lipid metabolism, we examined the effects of okadaic acid on the flux through these pathways. Okadaic acid mimicked the action of glucagon in increasing the rate of glucose output from hepatocytes, as well as the conversion of lactate to glucose (Fig. 2), as would be expected if the toxin increased phosphorylation of glycogen phosphorylase, glycogen synthase, pyruvate kinase and PFK2/FBPase. Okadaic acid stimulated basal lipolysis in adipocytes 2.6-fold (Fig. 3*a*), which is consistent with increased phosphorylation of hormone-sensitive lipase. A larger stimulation of lipolysis (10-fold) was observed in the presence of the adenosine agonist PIA, which causes inhibition of adenylate cyclase and reduces basal cAMP-dependent protein kinase activity and lipolysis[17] (Fig. 3*c*). Okadaic acid also completely prevented insulin from antagonizing the β-adrenergic activation of lipolysis (Fig. 3*b*).

Phosphorylation is known to inhibit acetyl CoA carboxylase, the rate-limiting enzyme in fatty acid biosynthesis[18], and we found that the activity of this enzyme was greatly decreased in extracts from okadaic acid-treated adipocytes (Fig. 3*d*). Acetyl CoA carboxylase activity itself was unaffected by inclusion of okadaic acid (1 μM) in the assays. There was a good correlation between inactivation of acetyl-CoA carboxylase and inhibition of insulin-stimulated fatty acid synthesis, as measured by incorporation of radioactivity from ^{14}C-labelled acetate into total lipid (Fig. 3*d*). Okadaic acid also inhibited the low rate of fatty acid synthesis observed in the absence of insulin (not shown).

Although okadaic acid antagonized the actions of insulin on fatty acid synthesis and lipolysis (Fig. 3), it mimicked the action

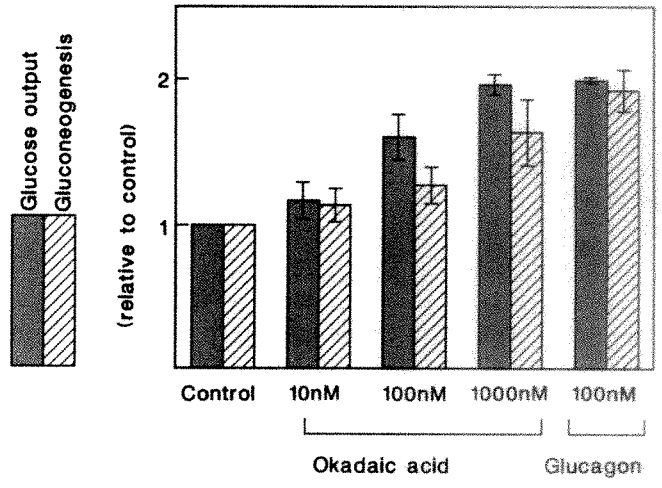

Fig. 2 Effects of okadaic acid on glucose output and gluconeogenesis in isolated hepatocytes from fed rats. Hepatocytes were isolated in medium containing 10 mM glucose and preincubated for 10 min with okadaic acid as in Fig. 1, except that the medium contained unlabelled phosphate. Gluconeogenesis was measured by the incorporation of radioactivity from [^{14}C]lactate into glucose[23]. Glucose output was measured using glucose oxidase (Sigma diagnostic kit 510-A); for these studies only, cells were collected by centrifugation and resuspended in medium without glucose immediately before addition of okadaic acid.

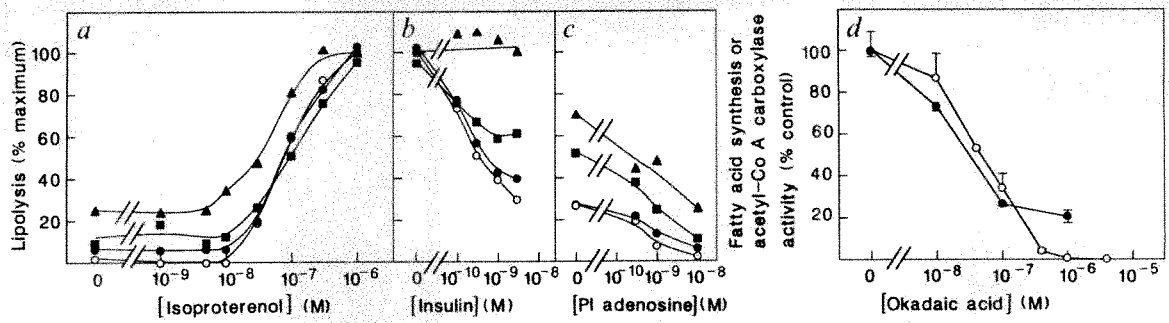

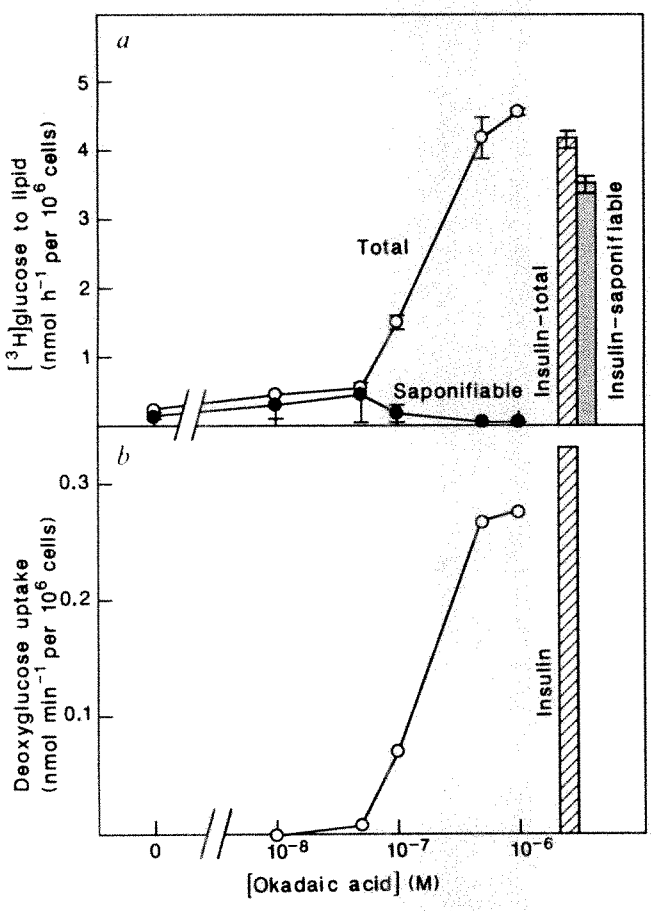

Fig. 3 Effects of okadaic acid treatment on metabolic parameters of isolated adipocytes. *a–c*, Effects of incubation for 25 min without okadaic acid (open circles), or with okadaic acid at 100 nM (filled circles), 300 nM (squares) or 1 μM (triangles) on lipolysis measured as glycerol release[17]. The adenosine agonist PIA (N^6-[*R*-(−)-1-methyl-2-phenethyl]adenosine, 100 nM) was present in *a*, and isoproterenol (1 μM) and PIA (100 nM) were present in *b*. *d*, Incorporation of radioactivity from [^{14}C]acetate into toluene extractable-lipid[24] (open circles) and acetyl CoA carboxylase activity (closed circles) measured at 10 mM citrate in the post-mitochondrial supernatant fraction[20].

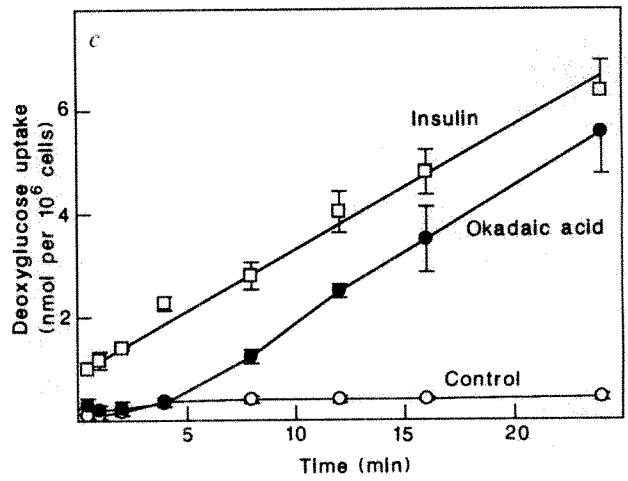

Fig. 4 Effects of okadaic acid and insulin on conversion of glucose into lipid and on 2-deoxyglucose uptake in adipocytes. *a*, Effect of okadaic acid on incorporation of radioactivity from [^{3}H]glucose into total toluene-extractable lipid (open circles) or saponifiable lipid (filled circles)[20]. The effects of a 10 min incubation with 0.9 nM insulin (total lipid, cross-hatched bar; saponifiable lipid, shaded bar) are also shown for comparison. *b*, Effect of okadaic acid on uptake of [^{14}C]-labelled 2-deoxyglucose into cells. The effect of a 10 min incubation with 0.9 nM insulin is shown by the cross-hatched bar. For both *a* and *b*, cells were preincubated with okadaic acid for 10 min before the measurement. *c*, Time course for uptake of [^{14}C]-labelled 2-deoxyglucose into cells treated in the absence of okadaic acid or insulin (open circles), or in the presence of 0.9 nM insulin (open squares) or 1 μM okadaic acid (filled circles). Deoxyglucose uptake was measured by incubating cells with 0.5 mM [U-^{14}C] 2-deoxyglucose (0.2 μCi ml^{-1}). Reactions were stopped by adding 200 μl aliquots of cells to 50 μM cytochalasin B (50 μl) and 50 μM phloretin in 0.25 × 4 cm polythene microtubes. 100 μl silicone oil (0.97 g ml^{-1}) was layered on top of the cells, and the tubes were then spun at 7,000*g* for 5 s in a bench centrifuge. The top half of the tubes containing the cells was cut off with a scalpel and dropped into 1 ml scintillation fluid (LKB Optiphase II) for counting. Control incubations showed that cytochalasin B and phloretin completely inhibited 2-deoxyglucose uptake in response to okadaic acid.

of insulin in dramatically enhancing the incorporation of radioactivity from [^{3}H]glucose into total lipid (Fig. 4*a*). But whereas 84% of the radioactivity incorporated into lipid was saponifiable (as fatty acid) in the case of insulin, <5% was saponifiable after treatment with okadaic acid. The simplest explanation for these results is that okadaic acid stimulated glucose transport while activating lipolysis and inhibiting fatty acid synthesis, so that most of the increased radioactivity would be glycerol-incorporated during triglyceride turnover. Insulin, however, stimulates glucose transport while inhibiting lipolysis and activating fatty acid synthesis, and radioactivity incorporated from glucose into triglyceride in this case would largely be present in fatty acid. To measure the effect of okadaic acid on glucose transport more directly, we studied the uptake of 2-deoxyglucose into adipocytes. After a lag of about 5 min, okadaic acid greatly stimulated uptake. Insulin produced the same effect, but without a significant lag (Fig. 4).

Our results strongly support the view that the effects of okadaic acid on cell function are explained by its ability to inhibit PP1 and/or PP2A. All effects on intact cells were maximal at 1 μM, which is similar to the *in vivo* concentration of PP1 and PP2A (ref. 11). None of the eight protein kinases tested to date (our data and refs 3 and 7) were affected by okadaic acid. Okadaic acid at 1 μM scarcely affects PP2B activity[5], and its specificity

is further emphasized by its failure to inhibit PP2C (ref. 4), pyruvate dehydrogenase phosphatase (T.A.J.H., unpublished results), protein tyrosine phosphatases, acid and alkaline phosphatases, and inositol trisphosphatase[4]. Furthermore, because okadaic acid stimulates glycogenolysis and gluconeogenesis in hepatocytes, and lipolysis and the conversion of glucose to glyceride-glycerol in adipocytes (Figs 2–4), and does not affect ATP or ADP levels, none of the enzymes in these metabolic pathways appears to be inhibited non-specifically by this compound.

Assays in cell-free extracts have shown that PP1, PP2A and PP2C account for virtually all the phosphatase activity in skeletal muscle and liver towards some 20 phosphoproteins that regulate several metabolic pathways and muscle contraction[9–11]. This study now strongly suggests that PP1 and PP2A, rather than PP2C, are the dominant phosphatase catalytic subunits acting on a wide range of phosphoproteins *in vivo*. The toxin is therefore a powerful probe for the investigation of the role of protein phosphorylation and of PP1/PP2A in any cellular event. It has already been shown to increase the calcium current in isolated myocytes[5], suggesting that the slow inward calcium channel is activated by phosphorylation in cardiac cells, and inactivated by PP1 and/or PP2A.

Although most of the effects of okadaic acid on protein phosphorylation and metabolism could have been predicted, the stimulation of glucose transport was unexpected, and the results are evidence that this process is activated by a protein serine/threonine phosphorylation event. The failure to observe phosphorylation of the glucose transporter in response to insulin[19], suggests that an associated regulatory protein may be the target for phosphorylation, rather than the transporter itself.

Because PP1 and PP2A are likely to be the chief enzymes that reverse the actions of protein kinase C, it is not surprising that a phosphatase inhibitor which can enter intact cells should be as potent a tumour promoter as substances that activate protein kinase C. Tumour promotion presumably stems from increased phosphorylation of one or more proteins that are substrates for protein kinase C and dephosphorylated by PP1/PP2A. The effects of okadaic acid on protein phosphorylation in isolated cells (Fig. 1) emphasize what a powerful tumour-suppressing effect PP1 and PP2A must have on normal cells.

The studies at Dundee were supported by the Medical Research Council, the Wellcome Trust and the British Heart Foundation. We thank Simon Pilkis for gifts of purified pyruvate kinase and PFK2/FBPase, and Richard Denton for useful discussions.

The pseudoautosomal boundary in man is defined by an *Alu* repeat sequence inserted on the Y chromosome

Nathan A. Ellis, Paul J. Goodfellow, Barbara Pym, Matthijs Smith, Mark Palmer, Anna-Maria Frischauf & Peter N. Goodfellow

Imperial Cancer Research Fund, 44 Lincoln's Inn Fields, London WC2A 3PX, UK

The Y chromosome, which in man determines the male sex (reviewed in ref. 1), is composed of two functionally distinct regions. The pseudoautosomal region is shared between the X and Y chromosome and is probably required for the correct segregation of the sex chromosomes during male meiosis[2]. The second region includes the sex-determining gene(s), the presence of which is necessary for the development of testes. The two regions have contrasting genetic properties: the pseudoautosomal region recombines between the X and Y chromosome[3]; the Y-specific region must avoid recombination otherwise the chromosomal basis of sex-determination breaks down[1]. The pseudoautosomal region is bounded at the distal end by the telomere and at the proximal end by X- and Y-specific DNA. We have found that the proximal boundary was formed by the insertion of an *Alu* sequence on the Y chromosome early in the primate lineage. Proximal to the *Alu* insertion there is a small region where similarity between the X and Y chromosomes is reduced and which is no longer subject to recombination.

Previous studies provided us with a defined region for the location of the pseudoautosomal boundary[4]. The *MIC2* gene is the closest marker known distal to the pseudoautosomal boundary and the probe (3′Rsa) is derived from the 3′-most exon of the *MIC2* gene. *DYS104* is the most distal Y-specific sequence that has been described[4]. To isolate the pseudoautosomal boundary we cloned 110 kilobases (kb) of DNA between the sequences defined by 3′Rsa and *DYS104* (Fig. 1). The Y-derived cosmid cAMF31 contains sequences that cross the pseudoautosomal boundary because it includes both Y-specific (H2.1) and pseudoautosomal sequences (E1.8). This places the boundary between 30 kb and 45 kb away from the sequences defined by 3′Rsa.

Two probes (Hf0.2 and RsY0.55) from cosmid cAMF31 were used to define the pseudoautosomal boundary: both probes are located on a Y-specific *Sac*I fragment of 3.3 kb (SacIY3.3; Fig. 2*a*). Hybridization of Hf0.2 to *Eco*RI and *Hae*III digests of DNA from females, from males and from somatic cell hybrids having the X chromosome and the Y chromosome as their only human contribution, reveals fragments of 1.8 kb and of 0.6 kb respectively (Fig. 2*b*, lanes 1–8). When Hf0.2 is hybridized to the same DNAs after *Sac*I digestion, fragments of 3.3 kb and 4.5 kb appear in male DNA but only one fragment of 4.5 kb is evident in female DNA (Fig. 2*b*, lanes 13 and 14). The 3.3-kb fragment is specific to the Y chromosome (lane 16) and the 4.5-kb fragment is specific to the X chromosome (lane 15). Similarly, Hf0.2 recognizes 2.4-kb and 2.8-kb *Rsa*I fragments in male DNA and only a 2.8-kb fragment in female DNA (lanes 9 and 10). The 2.4-kb fragment comes from the Y (lane 12), and the 2.8-kb fragment comes from the X (lane 11). Hence, the pseudoautosomal Hf0.2 probe maps Y-specific and X-specific restriction sites. The pseudoautosomal boundary lies between the *Eco*RI and *Rsa*I sites proximal to the sequences defined by Hf0.2.

The results in Fig. 2*c* confirm this conclusion. Hybridization of the RsY0.55 probe to the *Sac*I-digested DNAs presented in Fig. 2*b* reveals the 3.3-kb fragment in male and 'Y-only' DNA, but not in female and 'X-only' DNA. DNA from 64 females

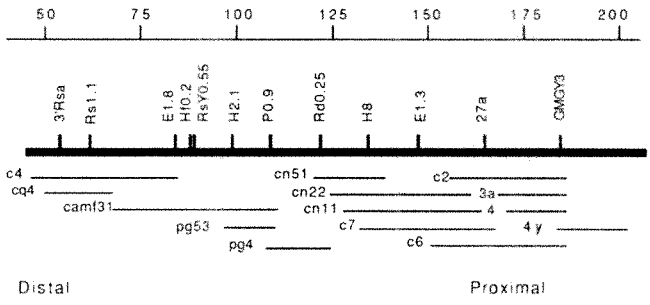

Fig. 1 Map of the region cloned in the chromosome walk. If the 5' CpG-rich region of *MIC2* is 0 kb, we set 3'Rsa at 55 kb on the long-range restriction map on the basis of partial cloning and Southern blotting of the *MIC2* gene[4,8]. Unique probes were isolated at each stage of the walk and their chromosomal origin determined by hybridization to gel transfers of DNA from female (WT49), male (PGF), 'X-only' somatic cell hybrid (Cl2D) and 'Y-only' somatic cell hybrid (853). Probe designations and clone sizes are shown. Cosmid clones are preceded by 'c'; all others are lambda clones. Probe 27a defines *DYS104* and GMGY3 defines *DYS13*. Probes H8, Rd0.25 and E1.8 need competition with sheared human placenta DNA[9].

Methods. Three cosmid libraries (one was donated by Peter Little and constructed with male DNA; the two others were constructed with male DNA and 853 DNA) and four lambda libraries (HL100 was constructed with male DNA and purchased from Clontech, and the other three were constructed with 853 DNA) were used in screening. Libraries were made by ligating genomic DNA, either partially digested with *Mbo*I or completely digested with *Eco*RI or *Hin*dIII, into appropriately digested pcos8 or λDASH (Stratagene) DNA, followed by packaging and transduction into P2392, ED8767 or NM621 *Escherichia coli* strains. Hybridization was in 6×SSC, 5×Denhardt's solution, 0.5% SDS, 0.25 mg ml^{-1} sheared and denatured DNA from salmon testes, and 2 ng ml^{-1} labelled probe. Probes were isolated on NA45 paper and labelled with ^{32}P by oligonucleotide reaction[10]. For hybridization with cosmid libraries, 0.1 mg ml^{-1} *Hae*III-digested and denatured vector DNA was added to prevent non-specific binding. The filters were washed twice at room temperature in 2×SSC and 0.2% SDS, then 3–5 times for 15 min in 0.2×SSC and 0.2% SDS at 65 °C, mounted and then exposed to XAR-5 with Cronex lightning-plus intensifier screens overnight.

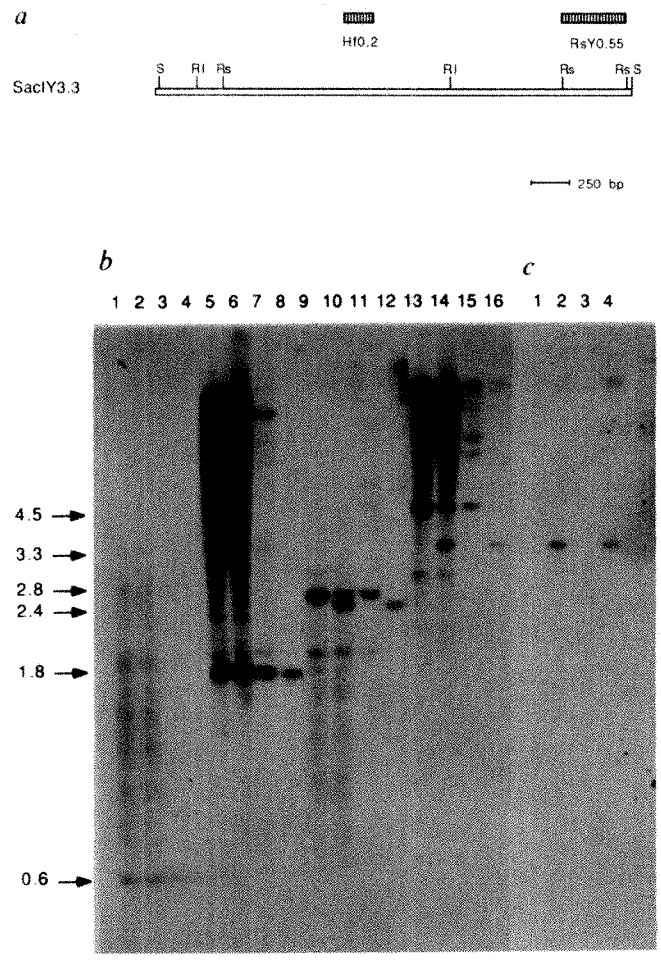

Fig. 2 Mapping the pseudoautosomal boundary with the Hf0.2 probe. *a*, Restriction map of SacIY3.3 and the two probes derived from it. Hf0.2 defines pseudoautosomal sequences and RsY0.55 defines Y-specific sequences. The 3.3-kb *Sac*I fragment from cAMF31 was subcloned into the *Sma*I site of pUC8. Hf0.2 and RsY0.55 were also subcloned into the *Sma*I site of pUC8. S, *Sac*I; RI, *Eco*RI; Rs, *Rsa*I. *b*, The Hf0.2 probe was hybridized to female, male, 'X-only' hybrid and 'Y-only' hybrid DNAs: WT49 (lanes 1, 5, 9 and 13), PGF (lanes 2, 6, 10 and 14), C12D (lanes 3, 7, 11 and 15) and 853 (lanes 4, 8, 12 and 16). Lanes 1–4 show DNA digested with *Hae*III; lanes 5–8, with *Eco*RI; lanes 9–12, with *Rsa*I and lanes 13–16, with *Sac*I. *c*, RsY0.55 was hybridized to the filter used in *b* after stripping it first. Lanes 1–4 are *Sac*I-digested DNA from female, male, 'X-only' hybrid and 'Y-only' hybrid.

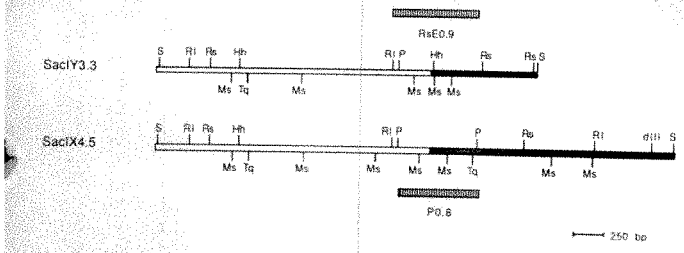
Methods. Each DNA (10 μg) was digested according to the supplier's instructions, electrophoresed through a 0.7% agarose gel and transferred on to GeneScreen Plus (NEN). Hybridization, post-hybridization washing and autoradiography have been previously described[11].

and 57 males was hybridized with the RsY0.55 probe: all the male samples, but none of the female samples, reacted with the probe. Therefore, the proximal pseudoautosomal region rarely, if ever, includes the sequences defined by RsY0.55 located on the Y chromosome.

X-specific sequences adjacent to the boundary were isolated by screening a lambda library with a probe derived from SacIY3.3. Overlapping clones λX31 and λX21 contain the pseudoautosomal 1.8-kb *Eco*RI fragment and the X-specific 4.5-kb *Sac*I fragment. The 4.5-kb *Sac*I fragment (SacIX4.5), which contains the X-side of the pseudoautosomal boundary, was subcloned and mapped using restriction enzymes (Fig. 3). The maps of SacIX4.5 and SacIY3.3 are nearly identical as far as the *Pst*I sites in the middle of each clone, but beyond this they are dissimilar. The pseudoautosomal boundary seems to lie in the region of ~50-base pair (bp) between the *Msp*I and *Hha*I sites on the Y chromosome (Fig. 3).

The 0.9-kb *Eco*RI/*Rsa*I fragment from SacIY3.3 (RsE0.9) and the 0.8-kb *Pst*I fragment from SacIX4.5 (P0.8) were subcloned (Fig. 3) and sequenced (Fig. 4*a* and *b*). As predicted by the restriction map, the boundary is located near the *Hha*I site. The two sequences diverge dramatically 245 bp proximal to the pseudoautosomal *Eco*RI site. Only two bases differ between the Y and X chromosomes at locations 201 bp and 205 bp from the *Eco*RI site. At the boundary on the Y chromosome, a 303-bp *Alu* repeat is inserted (Fig. 4*b*) and the first base pair of the *Alu* insertion is the first base-pair difference between the X and Y chromosomes. On the other side of the *Alu* insertion, homology between the X and Y chromosomes resumes and extends for 225 bp. The X and Y show 77% homology in this region. Beyond this point the sequences cannot be aligned by the IFIND:ALIGN (Intelligenetics) program. Figure 4*c* shows a schematic representation of the boundary region. Two regions of homology are separated by an *Alu* insertion, and proximal to these the sequences are non-homologous.

We propose that the pseudoautosomal boundary is precisely located at the point where the *Alu* sequence is inserted on the Y chromosome. Recombination has prevented sequence divergence in the region distal to the *Alu* (*Alu*-distal region). If the



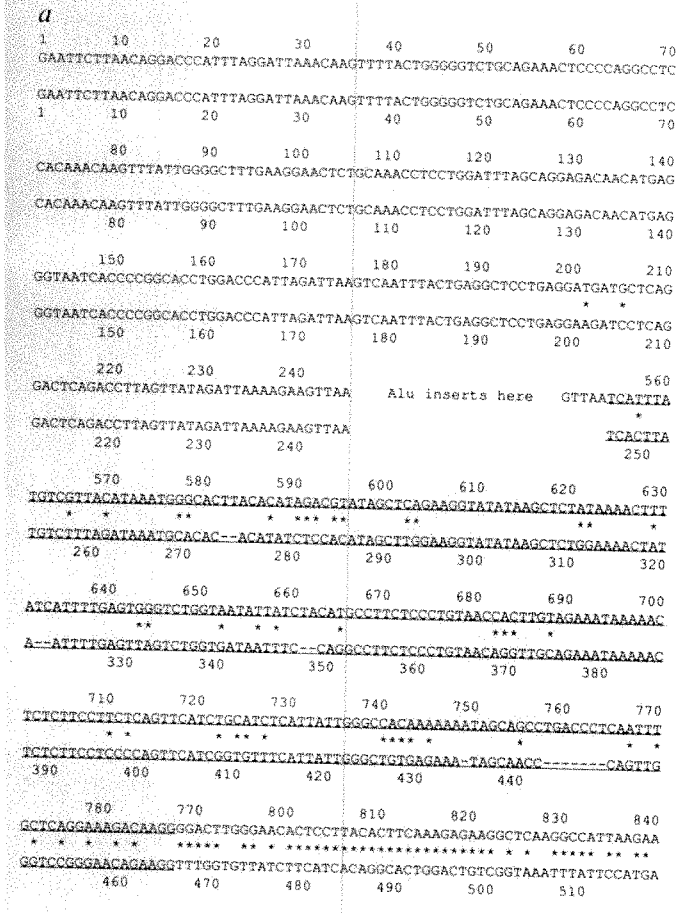


Fig. 3 A restriction map of the pseudoautosomal boundary. The lambda clones from which the X-specific 4.5-kb *Sac*I fragment is derived were isolated from a flow-sorted X-chromosome library (Los Alamos, ID code LA0XNL01). The fragment was subcloned into the *Sac*I site of Bluescript[c] (Stratagene). RsE0.9 was subcloned into *EcoR*I/*Sma*I-digested M13mp18 DNA and P0.8 into *Pst*I-digested pUC8 DNA. One *Msp*I site present in the SacIX4.5 is missing in the SacIY3.3. This site is associated with a restriction-fragment length polymorphism (data not shown).

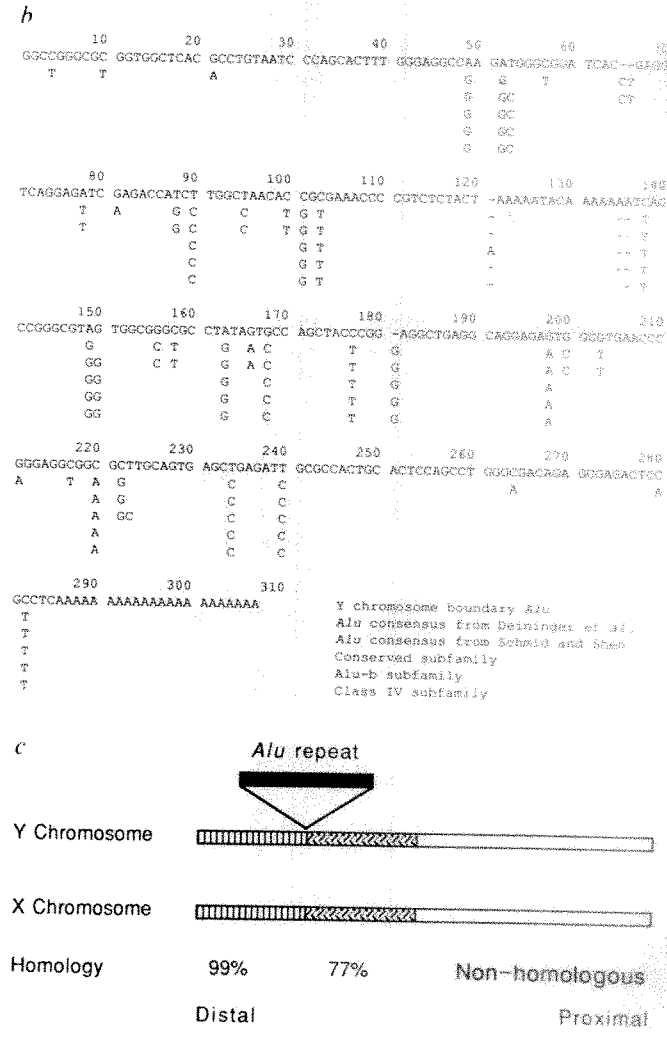

Fig. 4 DNA sequence of the pseudoautosomal boundary. Subclones were derived from the RsE0.9 and P0.8 in either pUC8 or Bluescript[c] and sequenced in double-stranded DNA by the dideoxy chain-termination method[12,13]. Oligonucleotides were used to complete the project. The sequence from the *Eco*RI site to the distal *Pst*I site on the X chromosome was derived from the appropriate 1.8-kb *Eco*RI subclone of SacIX4.5. *a*, The DNA sequence before and following the *Alu* insert on the X and Y chromosome is compared by removing the *Alu*. The *Alu*-proximal region is shown underlined, mismatches are starred and gaps are dashed. Note that multiple base changes frequently occur in the *Alu*-proximal region and that the gaps are all on the X chromosome. The complete sequence of the 947-bp RsE0.9 fragment and 771 bp from *Eco*RI to *Pst*I from SacIX4.5 is available on request. *b*, The *Alu* insert is compared with the consensus sequences from Deininger *et al.*[14] and from Schmid and Shen[15], and with the subfamily consensus sequences from Willard *et al.*[16], Jurka and Smith[17], and Britten *et al.*[18]. The *Alu* insertion appears to be a retroposition[19] because it ends with a string of 22 adenine nucleotides and has 5-bp direct repeats at each end (GTTAA). The *Alu* belongs to the conserved subfamily and has diverged by 6–7% from this group. *c*, Schematic drawing of the pseudoautosomal boundary shows the aligned *Alu* proximal and *Alu* distral regions with percentage homology represented as hatched lines, the *Alu* insert as a solid line, and X- and Y-specific regions as open lines.

mutation rate exceeded the probability of crossover between the mutation and the boundary, mutations would accumulate near the boundary. The pseudoautosomal region undergoes recombination at an average rate of 1% (10^{-2}) per 5×10^4 bp, therefore the recombination rate is 2×10^{-7} per meiosis per base pair[3]. If we make the parsimonious assumption that there is one meiosis per generation, and three generations every 100 years, we get a recombination rate of 6×10^{-9} per bp per year. Given the rate of sequence evolution is $\sim1.5\times10^{-9}$ mutations per site per year[5], then the rate of recombination slightly exceeds the mutation rate at the boundary. The *Alu*-distal region shows only two base differences out of 245 bp, which is consistent with our analysis; these two differences may be pseudoautosomal polymorphisms.

The fact that the region proximal to the *Alu* (*Alu*-proximal region) has diverged 23% implies that recombination has not maintained sequence similarity in this region. If recombination

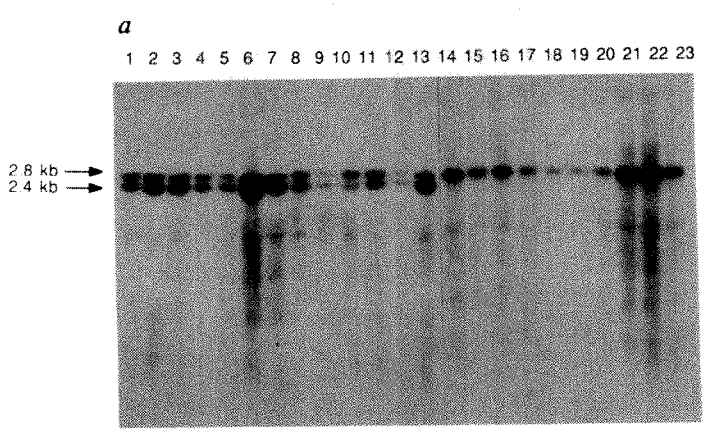

Fig. 5 Hybridization of the Hf0.2 probe to *Rsa*I-digested DNA from males and females. Female DNA shows a single 2.8-kb X-derived fragment; male DNA gives a 2.8-kb X-derived fragment and a 2.4-kb Y-derived fragment. *a*, DNAs from human males are in lanes 1–13 and DNAs from females in lanes 14–23. A total of 50 males, 25 females, an 'X-only' and a 'Y-only' hybrid was tested. Gel transfers were hybridized with RsY0.55 to test for Y-specific DNA. *b*, Male (odd-numbered lanes) and female (even-numbered lanes) DNAs from human (lanes 1 and 2), chimpanzee (lanes 3 and 4) and gorilla (lanes 5 and 6).

were occurring in the *Alu*-proximal region, then the *Alu* insertion would be present in females as well as in males. To test this hypothesis, we hybridized the Hf0.2 probe to *Rsa*I-digested DNA from males and females. Hf0.2 detects *Rsa*I fragments of 2.4 kb and 2.8 kb which cross the pseudoautosomal boundary. If recombination is occurring within the *Alu*-proximal region, the *Alu* is transferred to the X and increases the size of the X-specific *Rsa*I fragment to 3.1 kb, decreasing the Y-specific *Rsa*I fragment to 2.1 kb. We have already shown that sequences defined by the RsY0.55 are not found in females, but if recombination were to occur within or proximal to this locus, then hybridization with Hf0.2 would reveal a 2.4-kb *Rsa*I fragment in female DNA. We have tested 50 males and 25 females for this effect (see Fig. 5*a* for a subset of these results). In all cases, males had two fragments of 2.4 kb and 2.8 kb and females had only a 2.8-kb fragment. Moreover, in DNA from male and female gorillas and chimpanzees, we detected *Rsa*I fragments of identical size (Fig. 5*b*). We conclude that *Alu* insertion is of ancient origin and that recombination is not occurring in the *Alu*-proximal region. The base differences in the *Alu*-proximal region are uniformly distributed throughout the 225 bp, which suggests that divergence began for the whole region at once. This allows us to estimate the age of the human pseudoautosomal boundary. The common ancestor of the 225-bp region on the X and Y chromosome differs by 11.5% (23% ÷ 2) from that found today, which dates the boundary at ~45 million years old[6]. Unless other structural rearrangements have occurred, the previous boundary was 225 bp proximal to the *Alu* insertion and was also abrupt (Fig. 4*a*), as sequences proximal to the *Alu*-proximal region are non-homologous.

It is clear that the boundary has been created by the juxtaposition of nonhomologous sequences. Local maintenance of the boundary appears to be due, at least in part, to suppression of recombination caused by the nonhomologous sequences. Previously we suggested that the boundary could be limited by sex chromosome-specific functional genes or regulatory elements[7]. DNA sequencing and searching of databases has failed to provide evidence for such sequences close to the boundary on the X or the Y chromosome.

In summary, we have cloned and sequenced the pseudoautosomal boundary in man. The present-day boundary is defined by the insertion of a 303-bp *Alu* repeat sequence in the Y chromosome. Sequences immediately adjacent to the *Alu* insertion are identical, implying recombination occurs up to the *Alu*. The *Alu* insertion itself is Y-specific. Therefore the boundary is an abrupt change located at the *Alu*. Proximal to the *Alu* is a 225-bp region of X–Y homology which has diverged by 23%, suggesting the existence of an earlier boundary located 225 bp proximal to the *Alu*. We suggest that the absence of sequence homology was enough to create the pseudoautosomal boundary. Studies in primates should definitively date the *Alu* insertion.

We thank Peter Little for a cosmid library, Nigel Spurr for gel transfers of DNA from males and females, Ian Goldsmith of the ICRF's oligonucleotide synthesis group for oligonucleotides, and Kim Richardson for secretarial assistance.

Mitochondrial splicing requires a protein from a novel helicase family

Bertrand Séraphin*, Michel Simon, Annick Boulet & Gérard Faye

Institut Curie-Biologie, Bat. 110, Centre Universitaire, 91405 Orsay Cedex, France

Proteins involved in mitochondrial splicing but encoded by nuclear genes have been characterized in *Saccharomyces* and *Neurospora*[1–5]. The role in splicing of these proteins is largely unknown. Here we report that mutations in the nuclear gene *MSS116* directly affect the splicing of several introns of the cytochrome *b* (*cob*) and cytochrome *c* oxidase subunit I (*cox1*) primary transcripts. This implies that the MSS116 protein (pMSS116) is an important component of the mitochondrial splicing machinery. The sequence of the cloned *MSS116* gene shows that its protein product is homologous to the translation eIF-4A factor and the human nuclear protein p68. We show further that these proteins share several conserved amino-acid blocks with DNA helicases and related proteins. This suggests that pMSS116 has an RNA helicase activity. RNA helicases may be involved in many different processes including translation and splicing.

* Present address: Department of Biology, Brandeis University, Waltham, Massachusetts 02254, USA

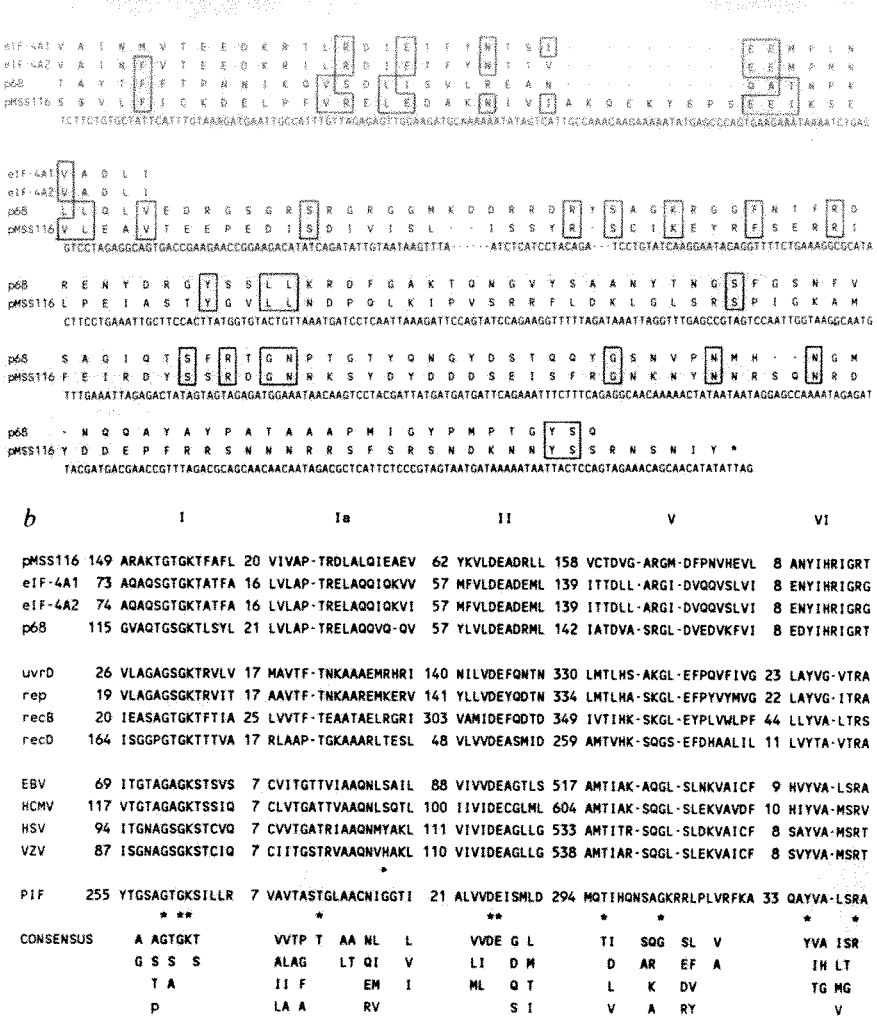

Fig. 1 Relationship of pMSS116 with eIF-4A, p68 and other helicases and replicative proteins. *a*, Alignment of the deduced amino-acid sequence of pMSS116 with the amino-acid sequence of eIF-4A1, eIF-4A2 (ref. 13) and p68 (ref. 14). Amino acids identical between pMSS116 and the other proteins are boxed. Note that conservative substitutions also occur at numerous positions. A hyphen indicates a gap introduced in the sequence to maximize similarity. Blocks I, I*a*, II, V and VI presented in *b* are overlined. The sequence of the *MSS116* gene is presented below the deduced pMSS116 protein sequence. *b*, Similarity between the eIF-4A/pMSS116/p68 protein family and helicases and replicative proteins. Blocks I, I*a*, II, V and VI have been defined by Hodgman for uvrD, rep, recB, recD, EBV, HCMV, HSV, VZV and PIF (see ref. 18 and refs therein). We have aligned for comparison the homologous blocks found in pMSS116, eIF-4A and p68. Blocks I and II probably form the ATP-binding site. Blocks Ia, V and VI have only been observed in helicase and replicative proteins but their function is unknown. Asterisks indicate amino acids conserved in all sequences. The consensus was derived by selecting positions where four or fewer amino acids occur.

We recently described a genetic screen for yeast nuclear mutants which specifically affect mitochondrial splicing[6]. Among the selected mutants, petA179 (renamed *mss116-2* here) is allelic to *mss116-1* which was shown, by Northern screening analysis, to impede the splicing of *cox1* transcript[7]. Northern experiments showed that mutation *mss116-2* has a drastic effect on the processing of primary transcripts (pre-mRNA) in a strain harbouring five introns in the *cob* gene and seven in the *cox1* gene (see Fig. 2 in ref. 6). A block in the splicing of one or several mitochondrial introns gives rise to a respiratory deficient phenotype. To find out which of the 13 known introns is dependent upon a wild-type MSS116 protein for splicing, mitochondrial genomes containing various sets of introns were introduced by cytoduction[6,8] into strains carrying either of the two mutant alleles. Lack of growth of the resulting cytoductants on glycerol (that is, their inability to respire) indicates which intron(s) requires the wild-type *MSS116* gene product for splicing. The results of these experiments, described in Table 1, indicate that excision of introns a1 as well as a1$5\alpha$ and/or a1$5\beta$ of *cox1* and b1, b2 and/or b3 of *cob* pre-mRNA depends upon the activity of pMSS116.

To gain further insight into the *MSS116* gene function, we cloned the wild-type allele by complementation in yeast and localized it within a 3-kb *Hin*dIII fragment. Its sequence shows a long reading frame coding for a putative protein of 664 amino acids (Fig. 1*a*). Gene disruption experiments[9] confirmed that we had cloned the *MSS116* gene (data not shown). Interestingly, introduction of mitochondria devoid of the 13 mitochondrial introns into a strain carrying a disrupted *MSS116* gene (allele *mss116-3*) does not restore respiratory competence. This suggests that pMSS116 has multiple functions. An alternative explanation is that some unidentified intron may exist in yeast mitochondria.

When we searched data bases for proteins homologous to the pMSS116 amino-acid sequence, we found a remarkable homology with the murine translation factor eIF4A (ref. 10) (Fig. 1*a*). To show that pMSS116 is directly involved in the splicing of *cob* and *cox1* pre-mRNA, and is not a translation initiation factor, we analysed the incorporation of [^{35}S]methionine into mitochondrial proteins *in vivo*[11]. Results obtained from strains bearing a disrupted *MSS116* gene are shown in Fig. 2. It appears that in a strain carrying the 13 known mitochondrial introns (Fig. 2, lane 1) the cob and cox1 proteins are absent, whereas the other major mitochondrial proteins are expressed. But we have not shown whether both the cox3 and ATPase 6 proteins are synthesized. When these mitochondria are exchanged by cytoduction for those of GF134-6D (see Table 1), protein cob is indeed translated and a low, though detectable, level of protein cox1 is synthesized (Fig. 2, lane 3). These results show that pMS116 is not a factor affecting general translation initiation *per se*. But our preliminary analyses of mitochondrial translation in mss116 strain does not rule out the possibility that pMSS116 is an initiation factor specifically required for efficient translation of the cox1, cox3 or ATPase 6 mRNA (Fig. 2, lane 3). An alternative possibility is that pMSS116 may be in some way necessary for the synthesis of some intron-encoded proteins (maturases). Northern experiments revealed that in the mitochondrial M12-54 context the splicing efficiency of intron b11 is greatly reduced by the *mss116-2* mutation (data not shown). However b11 does not require mitochondrial-encoded maturases for its excision[12]. Thus, at least for intron b11, pMSS116 does not intervene in splicing via the synthesis of maturases. These data suggest that pMSS116 is directly involved in the excision of mitochondrial introns.

Recently a second murine initiation factor gene was characterized[13]. Its amino-acid sequence and that of a human protein p68 (ref. 14) is compared with pMSS116 and eIF4A in Fig. 1*a*. Alignment of the four proteins together displays a remarkable conservation of several long amino-acids blocks covering most of the eIF4A sequences (although the middle part is slightly less conserved). Pairwise comparison gives 22.1%, 26.9% and 26.4% identical residues between pMSS116 and p68, eIF4A1 and eIF4A2, respectively. Conservative substitutions have occurred at several other positions. The extreme N-terminal part of pMSS116 has no counterpart in any of the other three proteins. This region is rich in serine, threonine and basic amino acids, and is devoid of acidic residues. These are the characteristics of mitochondrial pre-sequences[15] and support the idea that pMSS116 is imported into the mitochondrion. The eIF4A polypeptide is involved in the melting or unwinding of RNA in the presence of ATP[16,17]. The human p68 polypeptide is supposed to have a DNA helicase activity *in vitro*[14]. This suggests that pMSS116 may also possess a helicase activity.

This suggestion is further strengthened by comparison of the protein sequences with recently reported consensus sequences found in replicative proteins[18]. These proteins include the uvrD and rep helicases as well as recB, UL5 and related proteins which are likely to possess helicase activity (see ref. 18 and references therein). Out of the seven domains described by Hodgman in these helicase and replicative proteins, five are clearly identifiable in pMSS116, p68 and eIF4A (Fig. 1*b*). Blocks I and II probably form part of the ATP binding site, whereas

Table 1 Mitochondrial intron contents of the *cob* and *cox1* genes, and the respiratory competence of strains carrying the *mss116-1* or *mss116-2* alleles

(*d*) D273-10B/G1/356-R6	+	−	−	−	+	+	−	−	+	+	−	−	+	+	+
(*e*) GF134-6D	+	−	−	−	+	+	−	−	−	+	−	−	−	ND	+
(*f*) UVA32	−	−	−	−	+	+	−	+	+	−	−	−	+	+	+
(*g*) GF167-7B	−	−	−	−	−	−	−	−	−	−	−	−	−	+	+

Strains indicated in the column 'origin of mitochondria' (GF204-1D excepted) are described in ref. 6. Mitochondria of these seven strains were introduced by cytoduction, via strain K5/2 (ref. 6), either in strain BS7-76-2/2 carrying allele *mss116-1* or in strain D273-M3A/A179/F11 carrying allele *mss116-2*. These three latter strains had their mitochondrial genome deleted (rho°) (ref. 6). Mitochondria intron contents: ω is the 21S ribosomal RNA intron, b1 to b5 are the cytochrome b introns (b1) and a1 to a5γ are the cytochrome oxidase subunit 1 introns (a1); + or − indicates that the intron is present or deleted. Introns b1, a1, a2 and a5γ belong to group II, the others to group I (compare with ref. 20 and references therein). Respiratory competence was tested on glycerol plates: + or −, growth or absence of growth; ND, not determined. Assuming that a block of the splicing of a1$5\alpha$ and/or a1$5\beta$ does not hamper the splicing of any of the five cob introns, we can reach the following conclusions. Mutation *mss116-1* in strain harbouring the mitochondria of D273-10B/A impedes the splicing of *cox1* pre-mRNA (ref. 7), whereas the cytochrome *b* protein is synthesized[11,25]; comparison of lines *a* and *c* implies that *MSS116* is necessary for the splicing of intron b11, b12 and/or b13. By comparing lines *c*, *d* and *f* and knowing that in the D273-10B/A mitochondrial context the splicing of intron a11 is severely deficient (data not shown) we can conclude that *MSS116* is necessary for the splicing of intron a11 and/or a1$5\alpha$ and/or a1$5\beta$. Comparison of lines *c* and *b* leads to the conclusion that *MSS116* is necessary for the splicing of a11 as well as a1$5\alpha$ and/or a1$5\beta$.

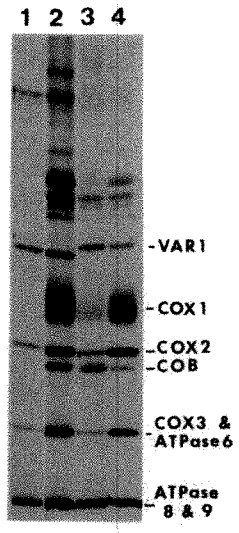

Fig. 2 ^{35}S-labelled mitochondrial translation products of strains, GRF18/B601B (lane 1), GRF18 (lane 2), BS102-1A (lane 3) and BS102-1B (lane 4). Cells were grown in galactose or raffinose complete media. They were labelled with [^{35}S] methionine in the presence of cycloheximide[11]. Radiolabelled mitochondrial translation products were prepared and analysed by SDS-PAGE[24]. Strains GRF18/B601B and BS102-1A bear a disrupted *MSS116* gene (allele *mss116-3*), the others a wild-type *MSS116* gene. Strains GRF18/B601B and GRF18 carry the 13 known mitochondrial introns, strains BS102-1A and BS102-1B have the mitochondria of GF134-6D (compare Table 1). The positions of the mitochondrially synthesized polypeptides are indicated: VAR1, var1 ribosomal protein; cox1, cox2 and cox3, subunits I, II and III of cytochrome *c* oxidase; COB, cytochrome *b*; ATPase 6, ATPase 8 and ATPase 9, subunits 6, 8 and 9 of mitochondrial oligomycin-sensitive ATPase.

blocks Ia, V and VI have only been observed in helicases and related proteins (Fig. 1*b*). These data indicate that the helicase/replicative protein super-family may be extended to include the more divergent eIF4A/p68/pMSS116 subfamily and reinforce the assumption that pMSS116 is an RNA helicase.

Several models may explain how an RNA helicase affects mitochondrial splicing. For example, folding of the nascent transcripts may give rise to several secondary structures in various proportions and only some of these structures will be compatible with a self-splicing activity. In support of this, only a fraction of the RNA present in an *in vitro* self-splicing reaction is active and the transition to the reactive state is the rate-limiting step[19]. An RNA helicase activity, by allowing a cycle of folding and unfolding to take place, will help each molecule reach the active configuration driving the reaction towards splicing of all pre-mRNA molecules. A differential propensity of various introns to non-functional folding will be reflected by different requirements for a helicase.

Another hypothesis is that changes in secondary and/or tertiary structures, which are likely to occur during splicing of mitochondrial introns, may be catalysed by a structure and/or sequence-specific helicase. Thus a folding pattern required early in the splicing process is melted later by a helicase allowing a new structure to form. During nuclear splicing, which is somewhat related to group II intron splicing[20], the U4 and U6 small nuclear RNAs follow a cycle of association and disassociation[21,22], and it has been suggested that a helicase may have a role in melting the two molecules apart[21,23].

We thank H. Fukuhara for encouragement and support, C. Wilson and R. Chanet for a critical reading of the manuscript.

The gene for the U6 small nuclear RNA in fission yeast has an intron

Tokio Tani & Yasumi Ohshima

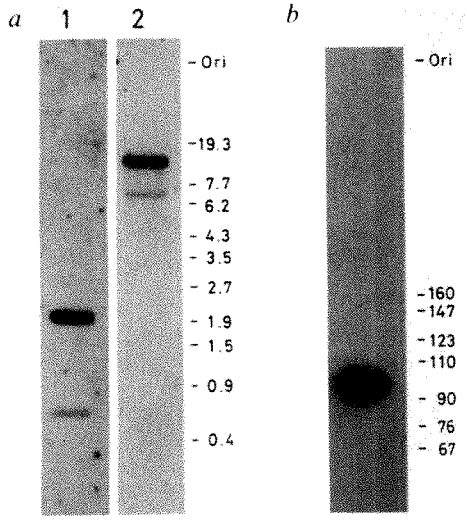
Department of Biology, Faculty of Science, Kyushu University, Hakozaki, Higashi-ku, Fukuoka 812, Japan

The small nuclear RNAs (snRNAs) are a class of metabolically stable small RNAs present in the nuclei of eukaryotic cells[1]. In mammalian cells, there are six major molecular species (U1 to U6 snRNA), which are complexed with proteins, forming small nuclear ribonucleoprotein particles, snRNPs. Of these, the U1, U2, U4, U5, U6 snRNPs are thought to participate in pre-mRNA splicing as part of the spliceosome (for review, see ref. 2). Here, we describe the characterization of the gene coding for the *Schizosaccharomyces pombe* U6 snRNA. Unexpectedly, the *Schiz. pombe* U6 RNA gene was found to contain an intron-like sequence of 50 base pairs. Northern blot analysis and RNA sequencing revealed that this intron-like sequence is precisely removed from the transcript. The mature U6 RNA of *Schiz. pombe* has 77% sequence homology with the mammalian U6 RNA. In *Schiz. pombe*, it is possible that U6 RNA is not only involved in pre-mRNA splicing, but is also a splicing substrate. This is the first report of an intron in a snRNA gene.

U6 RNA is one of the six abundant, capped snRNAs present in eukaryotic cells[3-9]. U6 and U4 RNAs are base-paired and are present in the same snRNP[10,11]. The U1, U2, U5, U4/U6 snRNPs assemble onto the pre-mRNA substrate to generate the active spliceosome[2]. U4 RNA is thought to be released from the assembled spliceosome during the splicing reaction[12]. The U1 snRNP interacts with the 5′ splice site, the U2 snRNP with the branch point, and the U5 snRNP may interact with the 3′ splice site. The exact function(s) of the U4/U6 snRNP in pre-mRNA splicing, however, is not known.

To elucidate the function(s) of U6 RNA, we isolated the gene coding for U6 RNA of the fission yeast *Schiz. pombe*, which is as convenient for genetic analysis and gene manipulation as the budding yeast *Saccharomyces cerevisiae*. In addition, it has been proposed that the splicing machinery of *Schiz. pombe* is closer than that of *Sacc. cerevisiae* to the machinery of higher eukaryotes[13].

The nucleotide sequence of U6 RNA is highly conserved among species[14]. We synthesized the 30-mer oligonucleotide complementary to the most conserved region of U6 RNA (nucleotides 40–69 of rat U6 RNA[5]) and used this as a probe, initially for Southern and northern blot analysis of the total



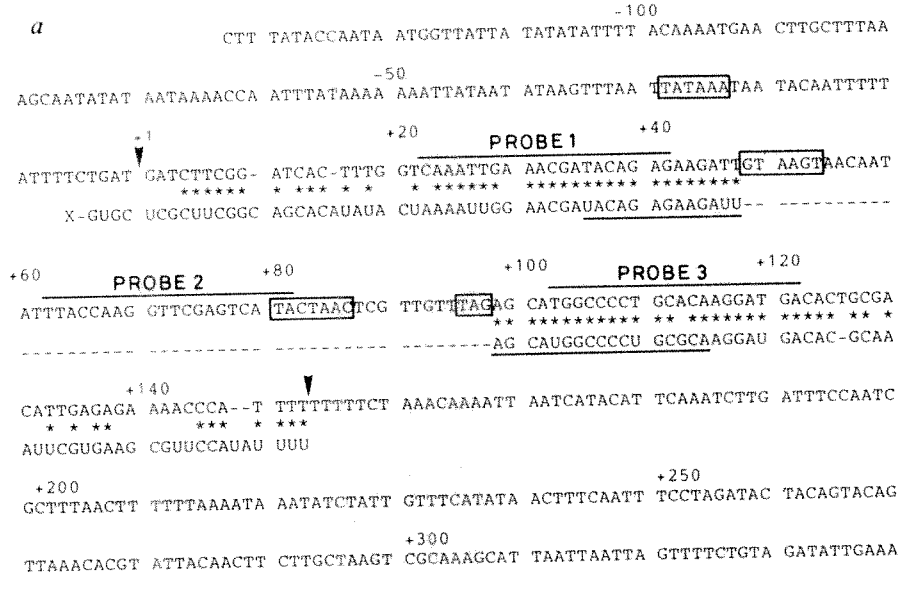


Fig. 1 *a*, Southern blot analysis of total DNA. Total *Schiz. pombe* DNA (10 μg) was digested with *Hin*dIII (lane 1) or *Pst*I (lane 2), electrophoresed on a 1% agarose gel, transferred to a Nylon membrane (Biodyne) and hybridized with the kinase-labelled oligonucleotide. Positions of size markers (λ *Sty*I digest) are on the right in kb. *b*, Northern blot analysis. *Schiz. pombe* total RNA (30 μg) was electrophoresed on a 5% polyacrylamide/7M urea gel, transferred to a Nylon membrane (Biodyne) by capillary action, and probed. Markers were kinase-labelled *Hpa*II fragments of pBR322 DNA.

Methods. Hybridization was at 42 °C in a solution containing 6× SSC, 50 mM sodium phosphate, 5× Denhardt's solution, 0.1% SDS, 2 mM EDTA and 20 μg ml^{-1} tRNA. The filter was washed in 3 M tetramethylammonium chloride, 2 mM EDTA, 50 mM Tris-HCl (*p*H 8.0) at room temperature for 30 min and then at 50 °C for 20 min. Autoradiography was carried out at −70 °C with an intensifying screen.

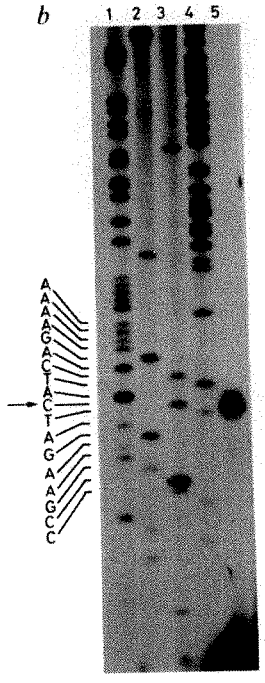

Fig. 2 *a*, Nucleotide sequence of the gene encoding the U6 RNA from *Schiz. pombe*. The upper line shows the sequence of the non-coding DNA strand. The lower line shows the sequence of the rat U6 RNA. Asterisks indicate identical nucleotides and dashes denote gaps introduced to optimize sequence homology. The 5′ and 3′ ends of the coding region were determined as described in the text and indicated by the vertical arrow heads. A presumptive 'TATA box' and the sequences similar to the consensus sequence of donor, acceptor and branch site are boxed. Numbers indicate distance in nucleotides from the predicted transcription initiation site. Overlines represent the sequences complementary to the probes used for northern blot analysis. Underlines indicate U6 RNA sequence (+40 to +69) complementary to the hybridization probe used for cloning. *b*, Mapping of the 5′ end of the coding region. The oligonucleotide complementary to the region +21 to +40 (probe 1) was used for primer extension reactions with total *Schiz. pombe* RNA (lane 5). The products of sequencing reactions using the same primer were run on lanes 1–4. The DNA sequence is written to the left of the panel. Primer extension reactions were performed as described[22].

Schiz. pombe DNA and RNA. Autoradiography of a Southern blot showed a single major hybridizing band of 2.0 kilobases (kb) and 9.3 kb and a minor band of 0.8 kb and 6.8 kb in the *Hin*dIII and *Pst*I digests, respectively (Fig. 1*a*). Similarly, a single major band of 100 nucleotides, close in size to that of mammalian U6 RNA, was detected by northern blot analysis (Fig. 1*b*). These results indicate that a gene which has strong homology with the probe is present at a single copy in the *Schiz. pombe* genome. We therefore constructed a genomic library derived from 1.5–2.5 kb *Hin*dIII fragments of *Schiz. pombe* DNA, and screened the library with the oligonucleotide probe. Positive clones were analysed by restriction mapping and nucleotide sequencing. All the positive clones analysed contained the same 2.0 kb fragment. Figure 2*a* shows the nucleotide sequence of the region that hybridized with the probe. A single U6 RNA gene was found in the 2.0 kb fragment. The 5′ end of the coding region was determined by primer extension (Fig. 2*b*) and RNA sequencing using the dideoxy method (data not shown). The 3′ end was tentatively assigned to be at +149 by a comparison with rat U6 RNA sequence. Although all U6 RNA genes cloned to date have a TATA box in the 5′-flanking region, several lines of evidence indicate that U6 RNA is transcribed by RNA polymerase III[3,6,15,16]. The putative 3′ end of the *Schiz. pombe* U6 RNA gene falls within a (T)-residue tract characteristic of transcription termination sites of RNA polymerase III.

Comparison of the nucleotide sequence of the coding region with that of rat U6 RNA revealed an unexpected structure of the *Schiz. pombe* U6 gene. Sequence identity with rat U6 RNA is abruptly interrupted at +47, and is resumed at +97. Interestingly, the 5′ and 3′ ends of the interruption are GTAAGT and TAG, respectively. These are identical to the consensus sequences at the ends of introns of all eukaryotic genes[17]. In addition, the sequence 5′-TACTAAC 3′, which is located 12 base pairs (bp) upstream of the 3′ boundary, matches the potential branch site sequence 5′-CTRAY-3′ present 6–18 residues upstream of the 3′ splice site of *Schiz. pombe* genes[18]. More remarkably, this sequence is identical to the TACTAAC box, the strictly conserved branch-site sequence found in *Sacc. cerevisiae*[19,20]. The distance between GT and AG is similar to the length of many *Schiz. pombe* introns. All these structural features suggest that the region +47 to +96 is an intron.

To investigate whether the intron-like sequence is actually an intron, we performed several experiments. First, northern blot analysis was carried out using the oligonucleotides complementary to three parts of the gene as probes (see Fig. 2*a*). As shown in Fig. 3*a*, probes 1 and 3 hybridized to RNA of the same size (about 100 nucleotides). In contrast, no hybridizing band was detected with probe 2, which is complementary to the intron-like region. These results suggest that the middle part of the transcript has been removed. Second, the partial nucleotide sequence of the *Schiz. pombe* U6 RNA was determined by the dideoxy method to localize the precise splice site (Fig. 3*b*). The nucleotide sequence of the mature U6 RNA indicates that the region +47 to +96 is indeed spliced out from the RNA. The U6 RNA sequence determined (68 nucleotides from the 5′ end) was completely co-linear with the gene sequence, except for the region +47 to +96. Furthermore, the size of the mature product (99 nucleotides) predicted from the gene sequence agrees well with the result of northern blot analysis. Third, we used Southern blot analysis with 12 restriction enzymes and probe 1 to exclude the possibility that there is an intron-less U6 gene. A single hybridizing band was detected in all cases, confirming that the *Schiz. pombe* U6 RNA gene is unique in the genome (data not shown). The minor bands (0.8 kb and 6.8 kb in *Hin*dIII and *Pst*I digests, respectively) were not detected with probe 1 even after a long exposure. Therefore, the minor band observed with the 30-mer probe does not seem to represent a U6 gene. Fourth, accumulation of a putative U6 RNA precursor of about 150 nucleotides was observed in *Schiz. pombe* which had been incubated at 43 °C for 30 min before RNA extraction (unpublished results). On the basis of these results we conclude that the *Schiz. pombe* U6 RNA gene has an intron.

The nucleotide sequence of U6 RNAs are highly conserved among species (Fig. 4). The mature *Schiz. pombe* U6 RNA has a 77% sequence identity with mammalian U6 RNA. The intron is present within the most conserved region of U6 RNA, the region thought to be important for U4:U6 interaction[10].

To our knowledge, this is the first example of an snRNA gene containing an intron. Although various snRNA genes have been cloned, none were found to have an intron. As for U6 RNA genes, introns have never been detected in genes from mammals[3,21], *Drosophila melanogaster*[9], *Xenopus tropicalis*[6] and the budding yeast *Sacc. cerevisiae*[7]. If *Schiz. pombe* U6 RNA is indeed a RNA polymerase III transcript, as it is in other organisms, the *Schiz. pombe* U6 RNA gene is the first gene to be transcribed by RNA polymerase III to have a typical mRNA intron. In the *Schiz. pombe* U6 RNA gene, the region corresponding to a 'box A' intragenic control sequence (5′-AGATTAG-CATGG-3′) of RNA polymerase III is disrupted by the intron

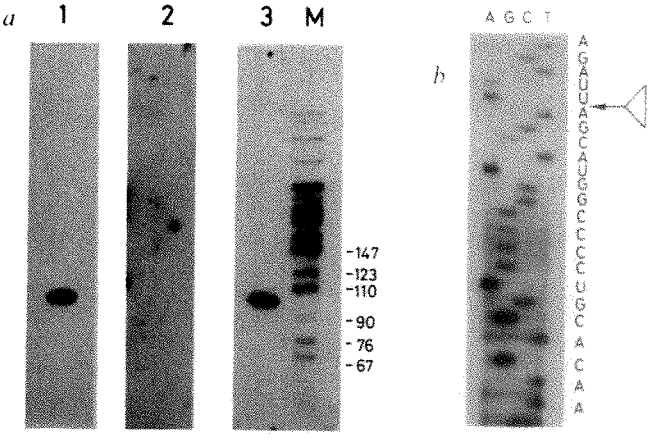

Fig. 3 *a*, Northern blot analysis. *Schiz. pombe* total RNA (30 μg) was electrophoresed on a 5% polyacrylamide/7 M urea gel, transferred to a Nylon membrane (Biodyne), and probed separately with the probe 1 (lane 1), probe 2 (lane 2) and probe 3 (lane 3). Hybridization conditions were the same as described in the Fig. 1 legend. Markers were kinase-labelled *Hpa*II fragments of pBR322 DNA (lane M). *b*, Sequence near the splice junction of the *Schiz. pombe* U6 RNA. The oligonucleotide complementary to the region +121 to +140 was kinase-labelled, and annealed to 30 μg of total *Schiz. pombe* RNA. The sample was split into four aliquots and used to direct cDNA synthesis[22] in the presence of ddATP (lane A), ddGTP (lane G), ddCTP (lane C), or ddTTP (lane T). Samples were run on a 8% polyacrylamide/8.3 M urea gel. The RNA sequence predicted by the cDNA sequence is written on the right side of the panel. The arrow shows the position where the intron sequence was located.

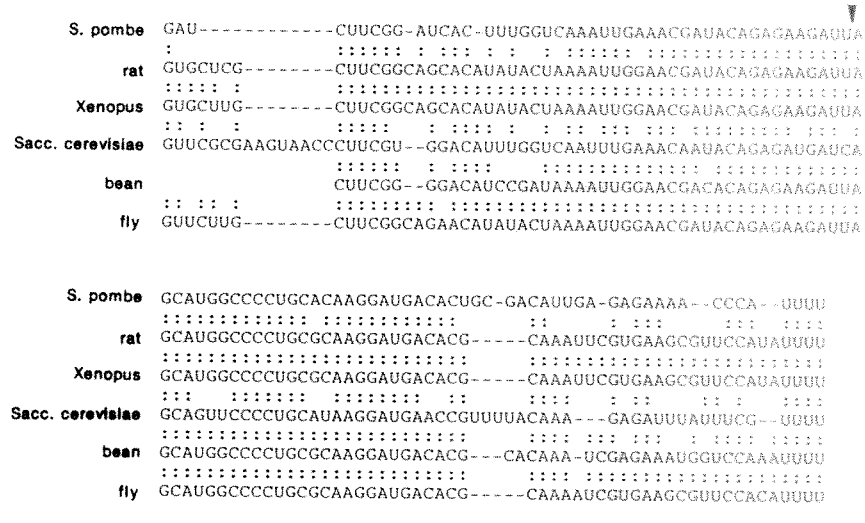

Fig. 4 Comparison of primary structures of U6 RNAs. The nucleotide sequence of the mature *Schiz. pombe* U6 RNA is aligned with that of U6 RNA from the rat[5], *Drosophila melanogaster*[9], *Xenopus tropicalis*[6], *Sacc. cerevisiae*[7], and broad bean (*Vicia faba* L.)[8]. Colons indicate the nucleotides identical to those of rat U6 RNA. Dashes represent gaps introduced to improve the alignment. The vertical arrowhead indicates the position of the intron present in the *Schiz. pombe* U6 RNA gene.

sequence. This sequence, however, is dispensable for efficient and accurate transcription of the vertebrate U6 RNA gene[15]. In addition, there is no consensus polymerase III intragenic sequence in the budding yeast U6 RNA gene, which is transcribed by yeast polymerase III[7].

It is surprising that the U6 RNA gene of fission yeast, with such a small genome size, has an intron. We do not know whether the intron of the U6 RNA gene has been removed in other organisms, or whether an intron sequence has jumped into the U6 RNA gene of *Schiz. pombe* during evolution. Oligonucleotide probe 2, which is complementary to the intron region gave a single major band corresponding to the cloned gene in Southern blots of the total *Schiz. pombe* DNA (data not shown). This would indicate that the U6 intron sequence is unique in the *Schiz. pombe* genome. It is, therefore, unlikely that the U6 intron is a kind of transposon.

It is possible that the *Schiz. pombe* U6 RNA is involved in RNA splicing as an RNA component of the spliceosome although U6 RNA itself is a substrate for RNA splicing. Probe 2 did not detect a band corresponding to the U6 RNA precursor on a northern blot, suggesting that the precursor is spliced very rapidly. If U6 RNA is a component of the splicing machinery, it must be very efficiently spliced, and thus must have the most efficient splicing signals. It is noteworthy that the intron of the *Schiz. pombe* U6 RNA gene has TACTAAC sequence, identical to the branch-site sequence of *Sacc. cerevisiae*.

The budding yeast gene for U6 RNA (SNR6) is reported to be essential for cell viability[7]. Gene disruption experiments are in progress to investigate whether the U6 RNA gene is essential for *Schiz. pombe*.

We thank Dr M. Yanagida for providing *Schiz. pombe* strains and M. Ohara for comments. This research was supported by grants from the Ministry of Education, Science and Culture of Japan.

Structural differences between a *ras* oncogene protein and the normal protein

Liang Tong, Abraham M. de Vos, Michael V. Milburn, Jarmila Jancarik, Shigeru Noguchi*, Susumu Nishimura*, Kazunobu Miura†, Eiko Ohtsuka† & Sung-Hou Kim‡

Department of Chemistry and Lawrence Berkeley Laboratory, University of California, Berkeley, California 94720, USA

† Faculty of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan

One of the most commonly found transforming *ras* oncogenes in human tumours has a valine codon replacing the glycine codon at position 12 of the normal c-Ha-*ras* gene[1–4]. To understand the structural reasons behind cell transformation arising from this single amino acid substitution, we have determined the crystal structure of the GDP-bound form of the mutant protein, p21(Val-12), encoded by this oncogene. We report here the overall structure of p21(Val-12) at 2.2 Å resolution and compare it with the structure of the normal c-Ha-*ras* protein[5]. One of the major differences is that the loop of the transforming *ras* protein that binds the β-phosphate of the guanine nucleotide is enlarged. Such a change in the 'catalytic site' conformation could explain the reduced GTPase activity of the mutant[6–8], which keeps the protein in the GTP bound 'signal on' state for a prolonged period of time, ultimately causing cell transformation.

The cloning and expression[9] of the synthetic gene coding for human c-Ha-*ras* p21 proteins and the crystallization conditions[10] have been described. Briefly, the synthetic gene (using *Escherichia coli* preferred codons) for amino-acid residues 1–171 was cloned and expressed in *E. coli*. We have deleted the codons corresponding to the carboxy-terminal 18 residues because there

‡ To whom correspondence should be addressed.

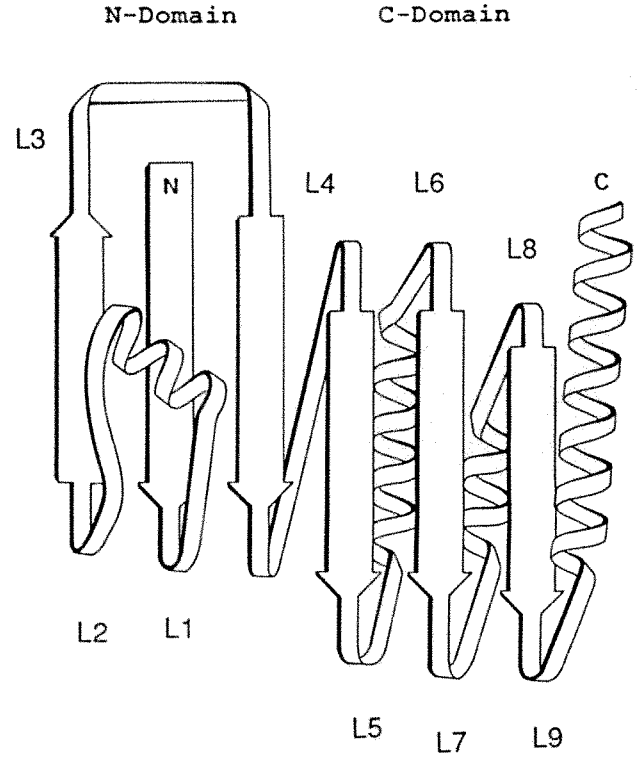

Fig. 1 Topological structure of human c-Ha-*ras* p21 protein. Each β-strand, α-helix and loop is numbered starting from the amino-terminus. The N-domain, which covers three β-strands and one α-helix, is barely hydrogen-bonded to the C-domain. The former has much higher thermal motion than the latter, suggesting that the flexibility of the N-domain is greater. The catalytic site for GTP hydrolysis is localized in the N-domain (phosphate binding domain) and the recognition for guanine base is in the C-domain (guanine recognition domain).

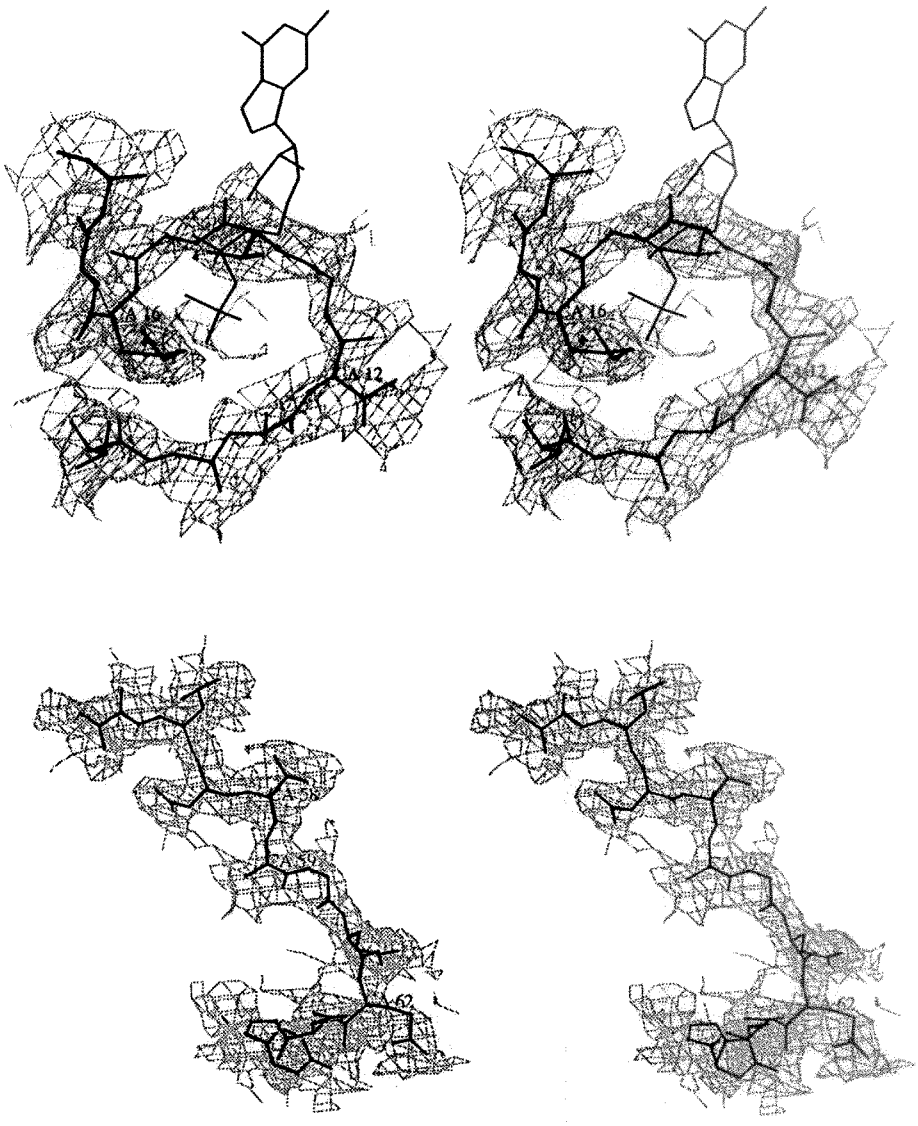

Fig. 2 Electron density maps for p21 (Val-12) around loop L1 and part of loop L4 with model fitting. These portions of electron density have been calculated with phases obtained from all atoms in the molecule, omitting those belonging to residues 9–18 and 55–64. The conformation of both regions in this mutant is different from that of normal p21.

is reasonable evidence that this region is flexible[11,12], and this flexibility could be detrimental to obtaining good quality crystals. Only the soluble fraction of the protein was purified for crystallization. The GTPase activity of p21(Val-12, 1–171) is less than 10% of that of the normal protein. High-quality single crystals were obtained from solutions containing 10 mg ml^{-1} protein, 0.1 M $CaCl_2$, 0.075 M HEPES buffer at *p*H 7.5, 0.5 mM EDTA, 0.5 mM dithiothreitol and 0.005% *n*-octyl glucoside, equilibrated to 30% PEG 400. The crystals are isomorphous with those of the normal protein, and have space group $P6_522$ with cell parameters $a = b = 83.2$ Å and $c = 105.1$ Å.

The diffraction data for p21(Val-12, 1–171) were collected on an Enraf Nonius rotation camera installed on the 8-pole wiggler line at the Stanford Synchrotron Radiation Laboratory, Palo Alto, California. The X-ray wavelength used for data collection was 1.08 Å, the crystal-to-film distance was 85 mm, and 2° rotation was used for each exposure. One set of data was collected from one crystal at 4 °C on a total of 32 films (16 film packs). The films were digitized on a drum scanner (P-1000, Optronics), and processed with a program originally written by Rossmann[13]. The reflection data from different films were then merged using the PROTEIN program package[14]. A total of 48,073 observations were used in the merging process, giving 10,447 unique reflections to 2.2 Å resolution, with an overall R(merge) on intensity of 8%.

The crystallographic refinement with the TNT program package[15] used the model for the normal protein[5] as a starting point.

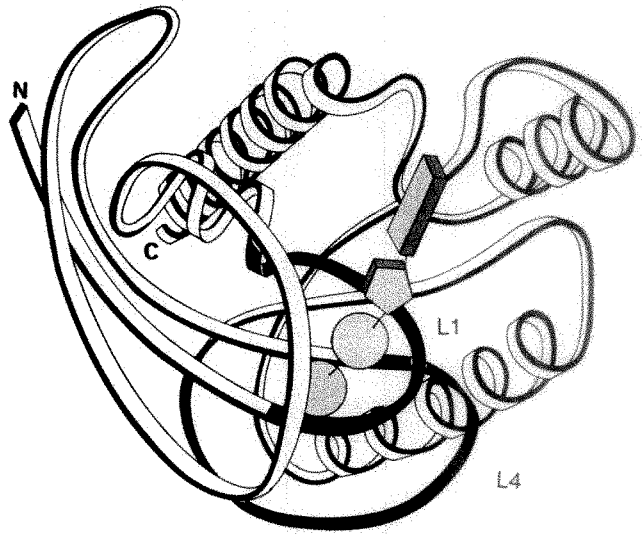

Fig. 3 An artist's drawing, looking down the guanine nucleotide-binding pocket, of the transforming human c-Ha-*ras* oncoprotein p21(Val-12) crystal structure. Cylinders, ribbons and thick black curves represent α-helices, β-strands and loops, respectively. The bound GDP molecule is identified by stippled shapes. The four loops L1, L2, L3 and L4 (Fig. 1) with conformation different from those in the normal protein are labelled.

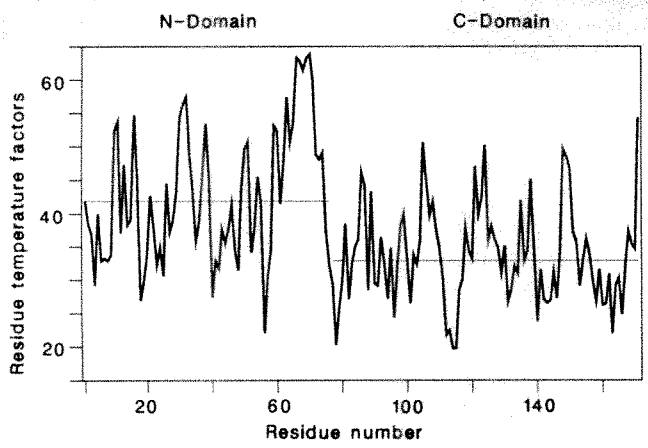

Fig. 4 Average main-chain temperature factors for p21(Val-12). The thin horizontal lines represent the average main-chain temperature factors for the N-terminal (1-75) and C-terminal (76-171) residues. Notice that the temperature factors for residues 60-75 of loop L4 are the highest in the structure.

During the course of refinement, omit maps were calculated by removing residues 9-18 and 55-64, corresponding to loop L1 and part of L4 (Fig. 1), and the model was refitted to the omit maps. Examples of such omit maps are shown in Fig. 2. The current R factor for 9,053 reflections between 10 and 2.2 Å resolution (80% of total possible) is 23.6%. A detailed description of the refinement and the refined structure will be reported elsewhere.

The overall structure (Fig. 3) of transforming p21(Val-12) is similar to that of the normal protein[5]. It contains six β-strands, four α-helices, and nine connecting loops (Fig. 1). Both structures seem to consist of two recognizable domains: the amino-terminal domain, containing the first 75 residues (including the first three β-strands and one α-helix), is the phosphate binding domain, and the carboxy-terminal domain, containing the remaining residues (including the last three β-strands and three α-helices), is the guanine recognition domain. There is only a short stretch of hydrogen bonding between β3 in the N-terminal domain and β4 in the C-terminal domain (Fig. 1). This separation of domains is also manifested by the distribution of the residue temperature factors in each domain (Fig. 4). The residues in the N-terminal domain have higher temperature factors (an average of 42 Å^2), and thus are more mobile than those in the C-terminal domain (an average of 33 Å^2). This high mobility of the N-terminal domain may have a functional significance in that it is in this domain where the catalytic site of GTP hydrolysis, the putative effector region[16,17], and the GTPase-activating protein-binding region (residues 30-40)[18,19] are located.

The differences between the two structures are mainly localized in the loops L1, L2, L3 and L4 in the N-terminal half of the molecule (Figs 1 and 3). The root-mean-square difference in Cα between p21(Val-12) and the normal protein is 1.26 Å for residues in the N-terminal domain (residues 1-75) and 0.56 Å for residues in the C-terminal domain (residues 76-171). At the current stage of the refinement, the two regions with the largest differences are located in loops L1 and L4. However, the electron density for residues in loop L4 is not as well-defined (as evidenced by their high-temperature factors, Fig. 4). Further refinement is required to assess the significance of the differences in this region.

The clearest and largest differences in structure were found in loop L1, corresponding to residues 9-18, which wraps around the β-phosphate of the bound GDP molecule (Fig. 5). The current refinement results from the normal protein, as well as from transforming p21(Val-12), show that there are several unusual features in this loop (Fig. 5). First, there seem to be no side chains, except that of Lys-16, involved in binding to the phosphate. Second, the backbone amide groups are pointing towards the β-phosphate, making hydrogen bonds to the phosphate oxygens and thus fixing the orientation of the β-phosphate, which is presumably important for GTPase activity. Third, there is a metal ion (probably Mg^{2+} or Ca^{2+}) coordinated to the oxygen atoms of the β-phosphate.

The simplest description of the structural differences in loop L1 is that the size of this loop in p21(Val-12) is much larger than in the normal protein (Fig. 5), resulting in the loss of two hydrogen bonds (from the backbone NH groups of residues 12 and 13) to the β-phosphate. We have suggested[5] that this loop would have straddled the phosphodiester bond between the β- and γ-phosphates of GTP, and therefore is the prime candidate to be the catalytic site for GTP hydrolysis in the normal p21 protein. The loss of two hydrogen bonds may alter the orientation of the β-phosphate, either when presented to the attacking group, or as a leaving group after the γ-phosphate is attacked, thereby changing the GTP hydrolysis rate. The position of the bound metal ion is such that it is a reasonable candidate for providing the attacking group (probably one of its bound water molecules) to the β-phosphate, perhaps for the on-line displacement of the γ-phosphate. Alternatively, the cation may be participating in fixing the β-phosphate in collaboration with backbone NH groups, with an as-yet-unidentified water molecule attacking the β-phosphate. Another mechanism, similar to that proposed for elongation factor Tu (ref. 20), is

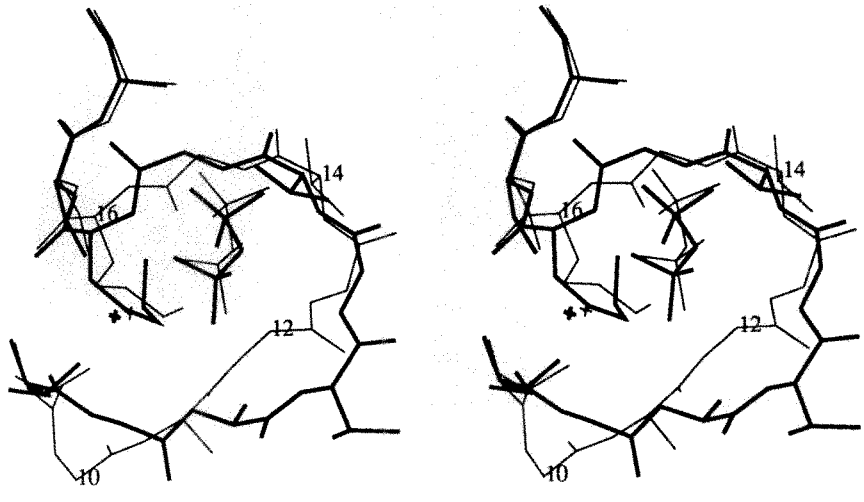

Fig. 5 A stereo view showing the conformation of Loop L1. The thick line is the conformation of loop L1 in p21(Val-12) and the thin line represents that of normal p21 protein. The small crosses represent the positions of the metal ions, and two phosphate groups are shown. Notice that the loop conformation around the β-phosphate in normal p21 protein is much tighter than that of p21 (Val-12).

that the γ-phosphate (which is not present in our structure) is attacked, possibly by a water molecule. This could explain the autophosphorylation activity of the viral *ras* proteins[21], because in that case the hydroxyl group of Thr-59 of viral p21, located near the presumed γ-phosphate site, could be the attacking group.

In summary, the crystal structure of transforming c-Ha-*ras* p21(Val-12, 1–171) with a bound GDP molecule provides a plausible explanation for the loss of GTPase activity of the protein, thus keeping the protein in the GTP-bound state, which is thought to signal continued cell proliferation without regulation. A complete understanding will have to await the structure determination of GTP bound c-Ha-*ras* p21 and of different activated mutants. Efforts to obtain p21 crystals with bound, non-hydrolysable GTP analogue and to determine the structure of the activated mutant p21(Leu-61, 1–171) are in progress. The coordinates will be deposited in the Brookhaven Protein Data Bank.

Structure of the membrane-pore-forming fragment of colicin A

M. W. Parker, F. Pattus, A. D. Tucker & D. Tsernoglou

European Molecular Biology Laboratory, Postfach 10.2209, 5900 Heidelberg, FRG

Colicins are antibiotic proteins produced by and active against sensitive *Escherichia coli* and closely related bacteria. They can adsorb to specific receptors located at the external surface of the outer membrane of sensitive cells, and are then translocated to their specific targets within these cells. The largest group of colicins comprises those which can form voltage-dependent channels in membranes, thereby destroying the cell's energy potential[1]. Colicin molecules are organized in structural domains, each domain carrying one function associated with the toxin's lethal activity. The pore-forming activity seems to be located at the carboxyl terminus. A thermolytic fragment comprising amino acids 389–592 from colicin A has pore-forming properties very similar to those of the entire molecule. This fragment is soluble in aqueous medium and spontaneously inserts into lipid bilayers[2]. We have determined the structure of the pore-forming fragment of colicin A by X-ray crystallography and refinement at 2.5 Å resolution. The protein consists of ten α-helices organized in a three-layer structure. Two of the helices are completely buried within the structure and form a hydrophobic hairpin loop similar to that proposed for signal sequences which function in translocation. We present a model for insertion of the protein into lipid bilayers the features of which may be applicable in other biological systems involving protein insertion or translocation across membranes.

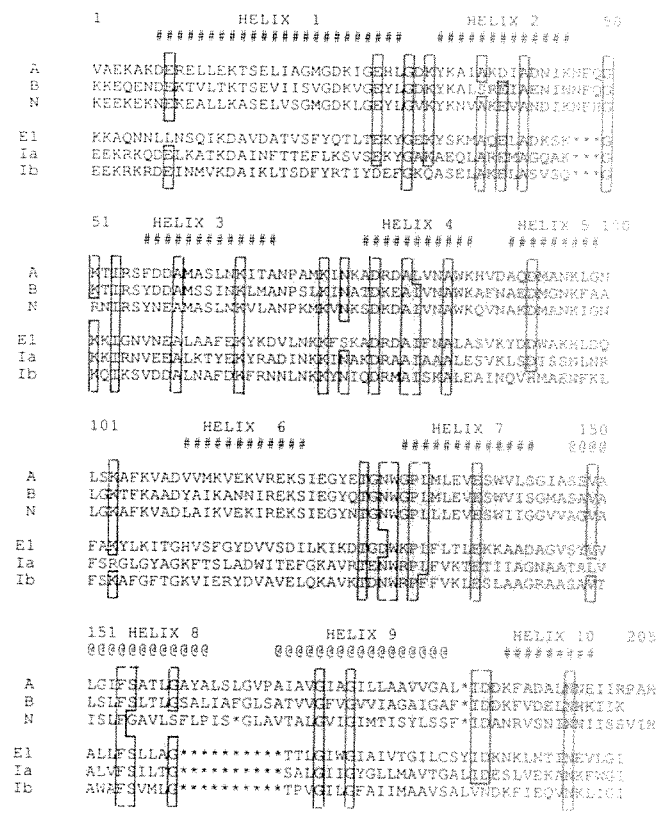

Fig. 1 Aligned sequences of the pore-forming domain of colicins. These sequences can be subdivided into two groups on the basis of sequence identity. Highly conserved residues are boxed. The position of alpha-helices in the sequence are shown. The # symbol refers to surface helices and the @ symbol to buried helices.

We have previously reported the crystallization of the thermolytic fragment of colicin A (ref. 3). The crystals belong to space group $P4_32_12$ with cell parameters $a = b = 73.0$ Å, $c = 171.3$ Å. There are two monomers per asymmetric unit. Diffraction data were measured on a multiwire area detector (Nicolet/Xentronics) mounted 20 cm from the crystal on a rotating anode X-ray generator (Elliot GX-18). The data sets were processed using the Genex software package[4]. Over thirty attempts to obtain an isomorphous derivative of the protein crystals using heavy-atom reagents were unsuccessful. Because the wild-type thermolytic fragment of colicin A contains no cysteines, and because mercurial reagents bound to cysteine residues often yield good isomorphous derivatives, we decided to use site-directed mutagenesis to construct cysteine mutants of the proteins (manuscript in preparation). The best heavy-atom derivative was made by soaking in mercury chloride the crystals of a mutant that had a serine replaced by a cysteine (Ser 16 → Cys, residue numbering as in Fig. 1) and a repeat decapeptide inserted just before it. The phase set constructed from this derivative was subsequently improved by application of solvent flattening techniques[5,6]. An atomic interpretation of the electron density map calculated at 3.0 Å resolution was constructed and refined using a combination of molecular dynamics[7,8] and the distance-

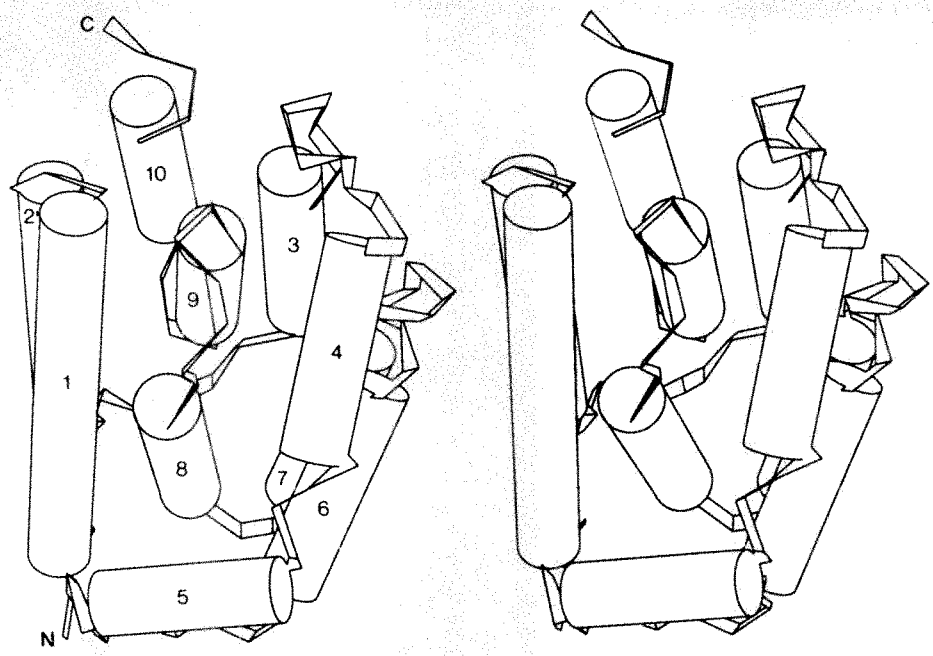

Fig. 2 Stereo representation of the chain fold of the pore-forming fragment of colicin A. Alpha-helices are represented by cylinders and are labelled 1 to 10. This figure was produced by a computer program written by Lesk and Hardman[27].

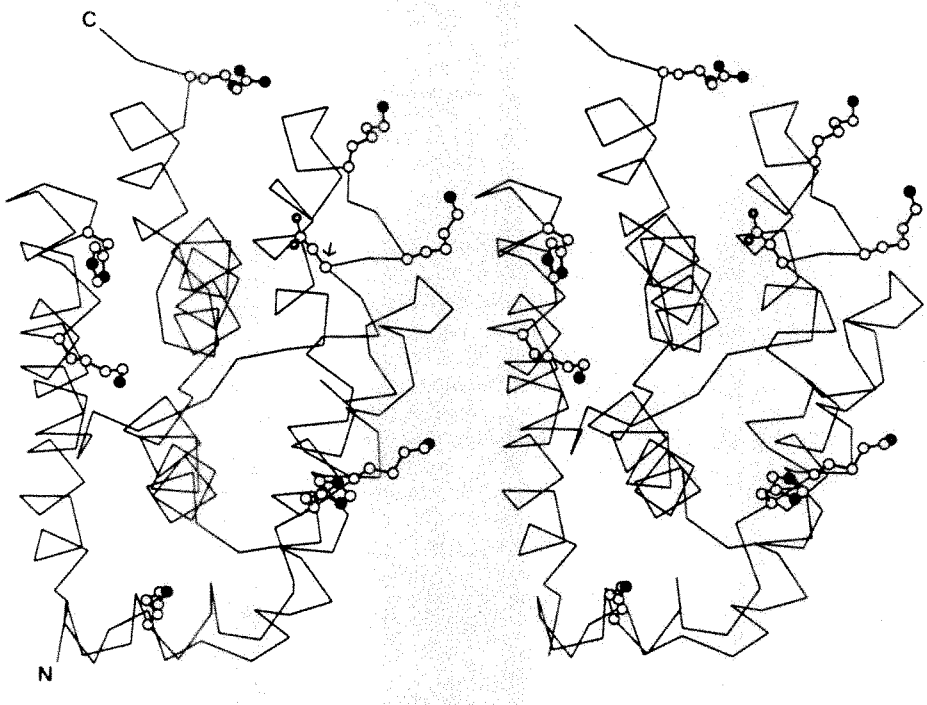

Fig. 3 Stereodiagram of an α-carbon representation of the chain fold showing the array of charged residues on the protein interface thought to interact with membranes. All residues are positively charged with the exception of Asp 78, which is indicated by an arrow. This figure was produced by a computer program written by Lesk and Hardman[27].

restrained least-squares procedure of Konnert and Hendrickson[9]. The current crystallographic *R*-factor of the refined model is 24.4% (10,024 reflections $> 3\sigma$, 6.0–2.5 Å, overall temperature factor). The r.m.s. deviation from ideal bond lengths is 0.024 Å. Details of the crystallographic work will be published elsewhere. For ease of discussion the terms 'thermolytic' or 'pore-forming' will be used interchangeably.

The structure of the pore-forming fragment of colicin A is presented in Fig. 2. The molecule can be described as a bundle of ten α-helices which are arranged in three layers. The layer containing the amino terminus of the peptide fragment consists of a pair of antiparallel amphipathic helices (helices 1 and 2). This N-terminal layer is connected by a long loop to another layer which consists of two pairs of antiparallel amphipathic helices (helices 3 and 4 and helices 6 and 7) with a helix (number 5) connecting the two helix pairs. The middle layer consists of three helices (helices 8, 9 and 10), the first two of which are completely buried and consist of hydrophobic residues only. The peptide fragment crystallizes as a dimer in the asymmetric unit of the unit cell. It should be noted that the protein normally exists as a monomer in solution and the monomeric state is considered to be the physiologically relevant state of the water-soluble form of the protein[10]. The dimer interface consists of contacts from the C-terminal end of helices 1, 3, 8 and 10, and from the N-terminal end of helices 2, 4 and 9, as well as contacts from residues in loops connecting these helices. Figure 2 has

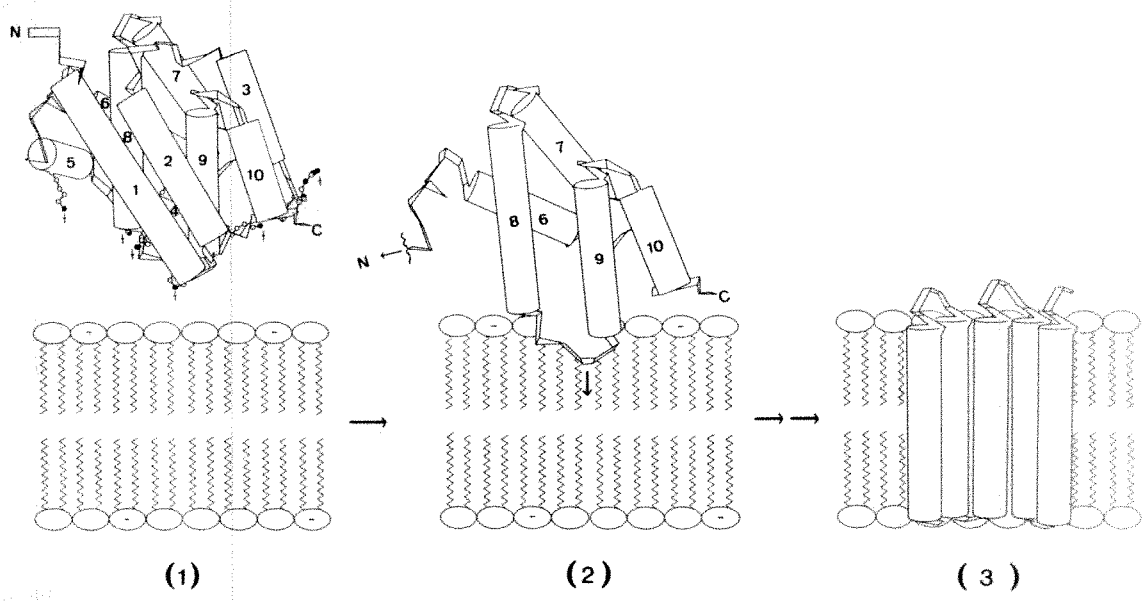

Fig. 4 A model for protein insertion into membranes suggested by the structure of the pore-forming fragment of colicin A. (1) Initial interaction with the membrane occurs as a result of the long-range interaction of an electrostatic potential field and shorter-range interactions such as salt bridges. The first step orientates the hydrophobic helical hairpin (helices 8 and 9) so that its axis is perpendicular to the membrane surface. (2) The hairpin spontaneously penetrates into the membrane, and in doing so initiates a conformational change in the protein. (3) It is envisaged that further steps involve insertion of other helical hairpins which may include oligomerization of the protein molecule. These final steps would lead to the formation of a voltage-gated channel.

been drawn so that this interface appears in the foreground plane of the diagram. The pore-forming fragment of colicin A is the second example of a three-layer α-helical fold first defined by citrate synthase[11]. There is no resemblance between the two proteins as far as structural details or function are concerned however.

The paradox that a colicin can exist as both a water-soluble protein and as a membrane protein is resolved by the structure of the pore-forming fragment of colicin A. Colicin A and its thermolytic fragment are soluble in water and monomeric over a wide range of *p*H and concentration conditions[10]. But the sequences of colicin A and related colicins all contain a hydrophobic stretch of residues between 35 and 49 amino acids long (Fig. 1). This stretch of sequence would be classified as a membrane-spanning sequence on the basis of hydropathy profiles[12]. In the three-dimensional structure, this membrane-spanning sequence adopts a helical hairpin motif (helices 8 and 9) which is completely buried within the protein. Thus residues that interact with lipid in the membrane-bound form of the protein are buried within the protein conformation of the water-soluble form.

The mechanism of insertion of a protein into a lipid bilayer can be divided into two steps: binding to the membrane surface and insertion of the protein into the hydrophobic core of the bilayer. The first step is probably electrostatic in nature, whereas the second may be driven by the partitioning of hydrophobic residues into the aliphatic environment of the bilayer. The electrostatic nature of the binding is supported by the following observations. Colicin A and its thermolytic fragment do not bind to neutral bilayers but display a great affinity for negatively charged lipids[13]. Binding can occur without insertion below the lipid phase transition. Penetration of the bilayer is optimized at acidic *p*H (the structure of the thermolytic fragment was determined at *p*H 4.4). The pore properties of colicin A suggest it is asymmetrically orientated with respect to the membrane. Analysis of the distribution of surface side chains of the pore-forming peptide structure shows that they are randomly distributed with respect to various potential interaction parameters such as charge, hydrophobicity and aromaticity. The exception to this finding occurs at the surface defined by the loop that connects helices 8 and 9 in the structure (Fig. 2). The loop is surrounded by a ring of eight positively charged side chains (residues 25, 29, 73, 76, 87, 88, 97 and 201; see Fig. 3). The only negatively charged residue on this surface is Asp 78 which is located inside the ring of positively charged residues (Fig. 3). It is striking that the interface defined by this loop and surrounding side chains is the same interface used in formation of the non-crystallographic dimer observed in the unit cell of the crystal. Thus this interface appears to have the potential to bind to surfaces found on proteins or lipid bilayers. The mean positive charge of the interface explains the affinity of colicin for negatively charged lipids.

The proposed orientation of binding of the pore-forming domain positions the hydrophobic helical hairpin directly above the membrane surface with helices 8 and 9 sitting perpendicular to the plane of the bilayer. Figure 2 has been drawn such that the proposed interaction surface of the peptide with the bilayer is placed in the foreground plane of the diagram. The positioning of the helical hairpin and the hydrophobic nature of the exposed loop connecting the two helices together with the loss of solvation at the peptide-membrane interface on binding promotes the insertion of the hairpin into the hydrophobic core of the bilayer. This implies that the structure must undergo significant conformational changes because the hairpin constitutes the hydrophobic core of the water soluble form of the protein. There is some evidence that supports a partial unfolding of colicin upon insertion into bilayers. Lowering the dielectric constant of the aqueous solvent with ethanol promotes the partial collapse of the far ultraviolet circular dichroism spectrum of the pore-forming peptide, whereas further addition of ethanol reverses the trend[12]. A similar effect is observed when the peptide is added to various concentrations of dimyristoylphosphatidyl glycerol vesicles at acidic *p*H (F. P., unpublished results). There is evidence of a drastic change in the mobility of some side chains on binding to lipid vesicles, as observed by circular dichroism spectroscopy in the near ultraviolet region (F.P., unpublished results). Proteolysis experiments indicate that the C-terminal helix does not get inserted, but is retained on the insertion side of the lipid bilayer[14].

At this stage there are not enough data to predict the protein

topology when inserted into the membrane. But it is noteworthy that the structure of the pore-forming fragment shows that helices are organized in a pairwise fashion. It is tempting to speculate that the insertion occurs by a stepwise insertion of helical hairpins without large changes in secondary structure conformation. The α-helical content of the water-soluble and lipid-bound form of the peptide fragment is identical, as judged by circular dichroism[12]. Mutation studies indicate that as few as 130 amino acid residues from the C-terminal end of the peptide are sufficient for pore formation[15]. A similar study of the homologous colicin E1 indicates that only the last 88 amino acids are required for pore formation[16]. These studies suggest that the insertion of the first helical hairpin (helices 8 and 9) into the membrane provides the energy for insertion of other helical hairpins. After insertion of the first helical hairpin, a large degree of hydrophobic association energy between the other helical hairpins would be lost, making the insertion of further hairpins more energetically favourable. The insertion of the first hairpin would bring the other hairpins closer to the membrane surface and hence make them more responsive to any electrochemical potential effects. Model-building suggests that the pore is probably formed by an oligomer of colicin molecules. An oligomerization process could have an important role in the insertion of other helical hairpins by shielding their polar faces from contact with the hydrophobic core of the membrane and forming the water-filled pore of the voltage-gated channel in doing so. Key features of the model for membrane insertion are presented in Fig. 4.

The three-dimensional structure of the pore-forming fragment of colicin A reveals a number of features relevant to the mechanism of protein insertion into membranes. The last sixty-odd residues at the extreme C-terminus of the protein show many features reminiscent of signal peptides that target proteins to bacterial plasma membranes or to the endoplasmic reticulum of eukaryotic cells. These features include a long stretch of hydrophobic residues with a centrally located glycine (residue 166), followed by a charged C-terminus containing basic residues[17] (Fig. 1). The signal-like peptide adopts a predominantly α-helical structure in colicin A, which is in accord with circular dichroism results for many signal peptides. The hydrophobic part of the signal-like peptide is almost completely buried in the protein, which provides an energetically favourable situation in which a signal peptide can be transferred through a water-soluble medium. It is known that deletions in the regions of the surface helices of the peptide fragment result in precipitation of such mutants in the cytoplasm of the producing cell and thus impede colicin export[15]. It follows that the shielding of the hydrophobic region of signal peptides in the water-soluble medium of a cell is an important feature of transported proteins. The helical hairpin structure of the signal-like peptide supports earlier theories that helical hairpin motifs would be a major feature in models of spontaneous insertion of proteins into membranes[18]. The structure resolves the paradox of how a water-soluble protein can also be incorporated into membranes. Surfaces required to interact with the hydrophobic core of membranes are buried within the conformation of the water-soluble form of the protein: colicin A is an 'inside-out' membrane protein. This result is consistent with other recent experimental data indicating that proteins require a flexible conformation in translocating across membranes[19–24].

The features suggested as being necessary for insertion of colicin A into membranes seem to apply, with some additional requirements, to a wide variety of biological systems. Prime examples include the membrane-attack complex of the complement cascade[25], the action of various toxins[25] and insertion of membrane precursors[26]. Current work is directed towards determining the structure of the membrane-bound form of colicin A to understand further the mechanism of insertion and to explain the pore properties of the voltage-gated channel formed.

We thank N. Didat and M.-P. Reck for technical assistance, Drs D. Baty, M. Chartier and C. Lazdunski for their role in the site-directed mutagenesis work, Dr P. Tucker for help with the X-ray diffraction data collection, and Drs B. Dobberstein, J. Lakey and S. Fuller for critical reading of the manuscript. We also thank C. Barber for assistance in preparation of the manuscript.

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

Nature is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature*'s staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

CATEGORIES OF PAPER

Review Articles survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

Colour Artwork. A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

Abbreviations, symbols, units and Greek letters should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

Acknowledgements should be brief. Grant numbers and contribution numbers are not allowed.

Submission. *All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT).*

Anti-Cancer Drug Design

An international journal covering an important area of common interest for medicinal chemists, biochemists, biophysicists and oncologists

- ☑ Concentrates on the rational scientific principles involved in the development of new anti-cancer agents
- ☑ Publishes original research papers which reflect the increasing importance of the tools of structural and molecular biology as well as the more traditional methodologies of pharmacology, chemistry and biophysics
- ☑ Publishes both experimental and clinically orientated papers
- ☑ Listed in Index Medicus, Excerpta Medica, BIOSIS and Current Contents

Recent contents include:

Relationship between the size and position of substituents on 7H-pyrido(4,3-c)carbazole monomers and dimers and their DNA binding and anti-tumour properties. **P Leon, C Garbay-Jaureguiberry, J B Le Pecq & B P Roques.**

Sulfhydryl-related reduction of the mitotic inhibition and cell inactivation induced by pyrimidine analogs. **M E H Nygaard, J M Dornish, E O Pettersen & R Oftebro.**

Lexitropsins: rational design of DNA sequence reading agents as novel anti-cancer agents and potential cellular probes. **J W Lown.**

The DNA-association and biological activity of a new bis(14-thiadaunomycin). **A Skorobagaty, R T C Brownlee, C J Chandler, I Kyratzis, D R Phillips, J A Reiss & H Trist.**

On a new class of mixed-function drugs associating nitroimidazoles and CENU: the NICE-NU. **A Carminati, J-L Barascut, E Chenut, C Bourut, G Mathe & J-L Imbach.**

Microbial mutagenicity of chlorambucil, its half-mustard and mitomycin C: a modified screening strategy for genetic toxicology of *bis*-alkylating anti-tumour drugs. **L R Ferguson, B D Palmer & W A Denny.**

PCR TECHNOLOGY Principles and Applications for DNA Amplification

Edited by Henry Erlich, PhD, Senior Scientist and Director of Human Genetics, Cetus Corporation

PCR (Polymerase Chain Reaction) technology is a revolutionary technique which enables scientists to rapidly generate large amounts of genetic material from a slight trace which would otherwise be too small to analyze. With applications in both research and diagnostics, PCR will soon become a standard procedure in biotechnology and medical diagnostic laboratories. *PCR Technology: Principles and Applications for DNA Amplification* is an introduction and guide to the technology. Written by the pioneers in the field, this is the authoritative publication detailing the methodology and the wide range of applications of PCR technology, including medicine, evolution and forensics.

Projected contents: INTRODUCTION TO THE PCR
History of PCR Development—Brief Essay • Description of the PCR Method—Basic Principles and Properties of the PCR • Thermostable DNA Polymerases • Automation • Sample Preparation
RESEARCH APPLICATIONS—BRIEF OVERVIEW
Direct Sequencing Using PCR • Preparation of Specific DNA Fragments Using PCR • Detection of Gene Expression • Genetic Mapping Using PCR Amplification of Individual Gametes
DIAGNOSTIC APPLICATIONS—BRIEF OVERVIEW
Detection of Pathogens • Diagnosis of Monogenic Genetic Diseases • HLA DNA Typing and Disease Susceptibility • Forensic Applications • Detection of Activated Oncogenes • Future Developments and Applications—Brief Essay

March 1989, approx. 176 pp., softcover 0-935859-56-X $19.95

The definitive dictionary of immunology . . .

Macmillan Dictionary of Immunology

Edited by F. Rosen, L. Steiner and E. Unanue
- *written by leading experts in the field*
- *definitions of almost 2,000 terms*
- *for clinicians, researchers and students*

The first comprehensive directory and dictionary of all known viruses in one reference source

Virology
Directory and Dictionary of Animal, Bacterial and Plant Viruses

Edited by R. Hull, F. Brown and C. Payne
- *internationally renowned authors*
- *Lists cell lines*
- *Provides equations, formulae and definitions*

The **Macmillan Dictionary of Immunology** Was compiled by leading immunologists to assist those who wish to keep up with research and developments in immunology. The **Dictionary** contains almost 2,000 definitions of terms used to describe the structure and function of antibody molecules, complement proteins, cell receptors, cell types, transplantation antigens and proteins, and mediators of immunologic reactions. Clinical and research oriented terms are included so that both physicians and researchers can keep abreast of the latest findings in the field.
December 1988, 200 pp., hardcover 0-333-347420 £25.00

Virology: Directory and Dictionary of Animal, Bacterial and Plant Viruses is an essential reference of all known viruses of animals (including invertebrates), plants and bacteria. This book is an indispensable reference work for all scientists working with viruses as biochemical tools or as the agents of infectious disease. Many general as well as technical terms are also defined including aspects of molecular biology and genetic manipulation. Virus nomenclature and classification used in the text follows the current terminology of the International Committee for Taxonomy of Viruses.
October 1988, 368 pp., hardcover 0-333-390636 £ 39.50

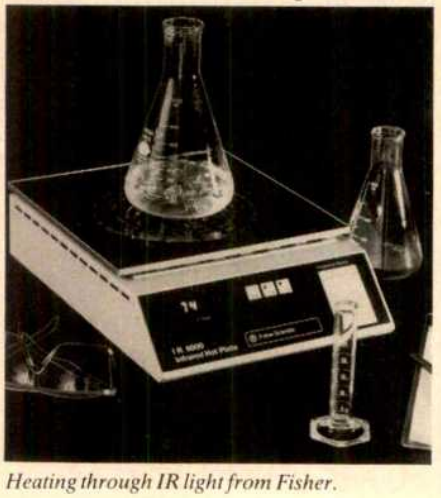
New products for a new year

Start the year off with a new addition to the laboratory — this week's selection includes an infrared hotplate, a software model for teratogenicity studies, and a balance that calculates molarity.

Bio Medical Equipment offers what may well be the most inexpensive **electrophoresis apparatus** on the market: the Mac Gel electrophoresis kit (*Reader Service No. 100*). For a total price of $10 (US), the Mac Gel kit contains two gel-forming plates, a multiwell comb, and platinum electrodes. Bio Medical Equipment's kit prepares standard-sized gels, and the entire apparatus fits into a buffer tank with ample dimensions for large buffer volumes. It is possible to use the electrodes with virtually any controller.

From Jordan Scientific comes a microcentrifuge **tube rack/beta shield** with a unique two-position lid (*Reader Service No. 101*). With the lid down, the rack is

Storage and safety are the two objectives fulfilled by Jordan Scientific's tube box.

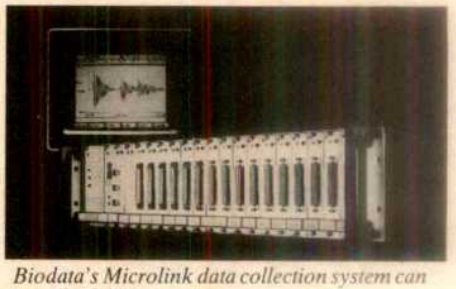


fully enclosed for the safe storage and transportation of tubes containing beta-emitting isotopes. In the upright position, the lid shields the user from radiation during pipetting operations or tube handling. The tube rack is made of one-half-inch-thick acrylic, and can withstand autoclaving. It holds 24 1.5-ml Eppendorf-type tubes in a four-by-six array, a configuration Jordan Scientific says is ideal for performing sequencing reactions. The tube rack costs $55 (US).

Lab essentials

The newest **spectrophotometer** from Pharmacia LKB is the Novaspec II, an instrument that the company terms "simplicity itself" (*Reader Service No. 102*). The compact Novaspec II performs absorbance and transmission measurements in only three steps: the required wavelength is set using the keypad, the reference blank is adjusted by one keystroke after inserting the blank cuvette, and the sample measurement is read off of the digital display. The instrument can make concentration measurements, perform simple kinetics calculations, and measure absorbance ratios and differences. It comes with a bi-directional RS232C interface for connection to a printer for hard-copy results. The Novaspec II's wavelength range is 325–900 nm, monitored by a single detector. It accepts both 10 mm cuvettes and standard-sized test tubes.

Sartorius has just announced the launch of a new series of **analytical balances** that can perform the necessary calculations for preparing molar solutions (*Reader Service No. 103*). The balances come equipped with Sartorius's Lab-Plus software, which has programs for statistical analyses, density determination, and classification and sorting operations. For preparing molar solutions, the operator keys in the molecular weight of the substance to be dissolved, the desired molarity and the target volume — the balance displays the amount of substance to be "filled toward zero". If the operator adds too much, the balance recalculates the target volume to attain the same molarity. The balances can weigh directly in moles, percent by volume or p.p.m. when provided the molecular weight and target volume. The capacity of the balances is 200 g, displayed down to 0.1 mg.

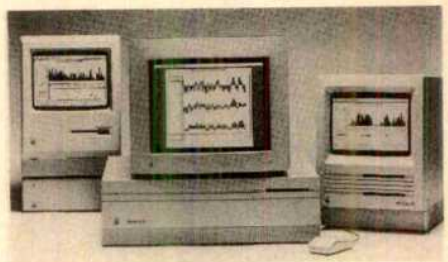


Fisher Scientific has a new **laboratory hotplate** that uses infrared light instead of an electrical heating unit, to provide a maximum temperature of 615 °C (*Reader Service No. 104*). The company says the hotplate can boil 1,000 ml of water in under 12 minutes in a 1.5-litre Erlenmyer flask — nearly twice the heating rate of most other hotplates. The $650 (US) IR-6000 hotplate is continuously adjustable over its power setting range of between 1 per cent and 99 per cent. Fisher Scientific says the hotplate assures greater uniformity of heating than traditional hotplates because it does not depend on the shape of the vessel bottom: the infrared light generated by the unit's molybdenum disilicide coil heats the sample directly. The glass-ceramic surface of the IR-6000 measures 12 × 12 inches, and its stainless steel edge can contain up to 400 ml of liquid in the event of a spill.

Heating through IR light from Fisher.

Computing

For those who collect large volumes of analogue data from laboratory instruments or transducers with voltage outputs, Biodata offers its Microlink high-speed **data collection system** (*Reader Service No. 105*). Biodata's system collects and streams data directly to the hard disk of an IBM microcomputer or compatible at rates of up to 25,000 samples per second. The data is available immediately for analysis, and the unit can store up to 16 million samples. The data acquisition hardware accepts up to 256 channels in one cabinet and incorporates 12-bit buffered analogue-to-digital conversion. Both voltage and thermocouple inputs can be used with the £4,000 (UK) Microlink system, which includes hardware, software and IBM-compatible computer.



Biodata's Microlink data collection system can handle 25,000 samples per second.

The HDi corporation offers an alternative to animal testing for **teratogen analysis** — a set of advanced structure- activity (SAR) models of teratogenesis coupled with its Topkat software (*Reader Service No. 106*). HDi says the models and the Topkat program can predict the teratogenicity of untested chemicals with an

accuracy of 96 per cent. The models are based on a data base of teratogenesis bioassays that HDi abstracted from the literature. Independent parameters in the SAR equations include electronic charges, substructural keys and topological descriptors. The model is based on four subequations, but this is transparent to the user: Topkat automatically selects the equation appropriate for the chemical to be estimated. HDi says the $15,000 (US) system correctly classifies carbocyclic aromatics, heterocyclic aromatics, acyclic aliphatics and alicyclics over 95 per cent of the time. Topkat also has modules to predict the probability of carcinogenicity, mutagenicity, skin and eye irritation, and values of acute toxic effects.

An interactive **graphics software package** for exploring, analysing, and visualizing technical data is new from Precision Visuals (*Reader Service No. 107*). PV-WAVE stands for Precision Visuals' Workstation Analysis and Visualization Environment. It allows researchers to navigate through large datasets, reduce and filter the data into manageable subsets, visually distinguish and analyse key features and trends, and translate results into publication-quality charts, graphs, contour maps, surface plots and images. Commands can be entered using the keyboard or be grouped into procedure files; application developers can create custom systems using PV-WAVE's menu development tools. Running on a VAXstation 2000, Precision Visuals says the software can read 2,400 floating-point numbers in 1.6 seconds, or compute a 4,096-point real-to-complex Fast Fourier Transform in 0.15 seconds. PV-WAVE costs $3,350 for the VAXstation 2000. Sun workstation versions will be released early this year.

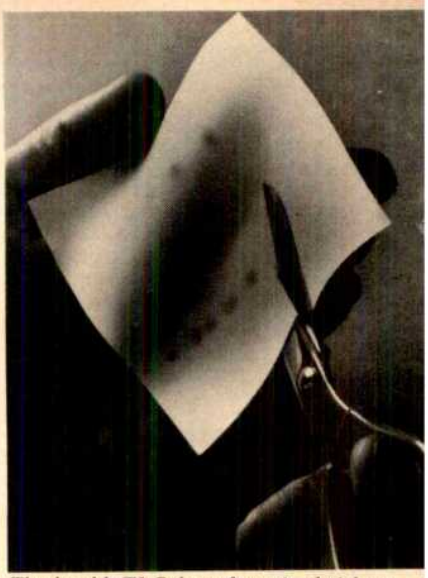
A desktop **DNA sequence analysis software package** for use with Macintosh computers has been introduced by International Biotechnologies, Inc. (*Reader Service No. 108*). The $2,295 (US) IBI Pustell Software for the Macintosh supports over 100 applications, including restriction analysis, homology matrices and protein structural studies. It also provides a global search function that matches DNA-DNA, protein-protein and protein-DNA with designated databases. The software interacts with and converts

DNA sequence analysis comes to the Macintosh computer with software from IBI.

to every major sequence format, says IBI, including that used in GenBank, Bionet, Staden, Line and UWGCG. A unique "wildcard" feature allows researchers to access data without complete reference information. IBI says researchers can use data from their Macintosh in a VAX or IBM-PC through a user-supplied interface, permitting users to share data with colleagues.

Analytical aids

Spectramass Ltd's BioQuad gas analysis system uses quadrupole mass spectrometry technology to **monitor fermentation** processes (*Reader Service No. 109*). The #15,000-19,000 (UK) system analyses inlet and exhaust gases, and provides data on dissolved gases and volatile substrates. The heart of the system is the Spectramass PC 2000 mass spectrometer, which has been designed with ion source optics especially suited for the analysis of complex gas streams. Spectramass says the analysis of dissolved gases and volatiles is easily accomplished using a membrane inlet system and probe to permit connection to standard fermenter ports. The BioQuad system includes vacuum components, remote-controlled valves and inlet lines, and software.



To protect HPLC equipment against damage from reagent backflow, Pickering Laboratories has designed its post-column **eluent flow interlock** (*Reader Service No.*

Prevent post-column eluent backflow with the interlock device from Pickering Labs.

110). The interlock system monitors pressure at the outlet of the eluent pump, and shuts off the power to the post-column system if the eluent pressure drops below 500 p.s.i., stopping reverse reagent flow that can damage both the analytical column and post-column equipment. Pickering Labs' interlock also shuts down the post-column system in the event of power loss, and a surge protection feature guards against electrical damage from voltage spikes. The $420 (US) interlock comes equipped with four 120-V receptacles, stats lights, reset button, circuit breaker, power cord and a pressure switch with a five-foot cord.

Analytichem has introduced a **thin-layer chromatography sheet** that it says is so flexible that spots can be cut or punched

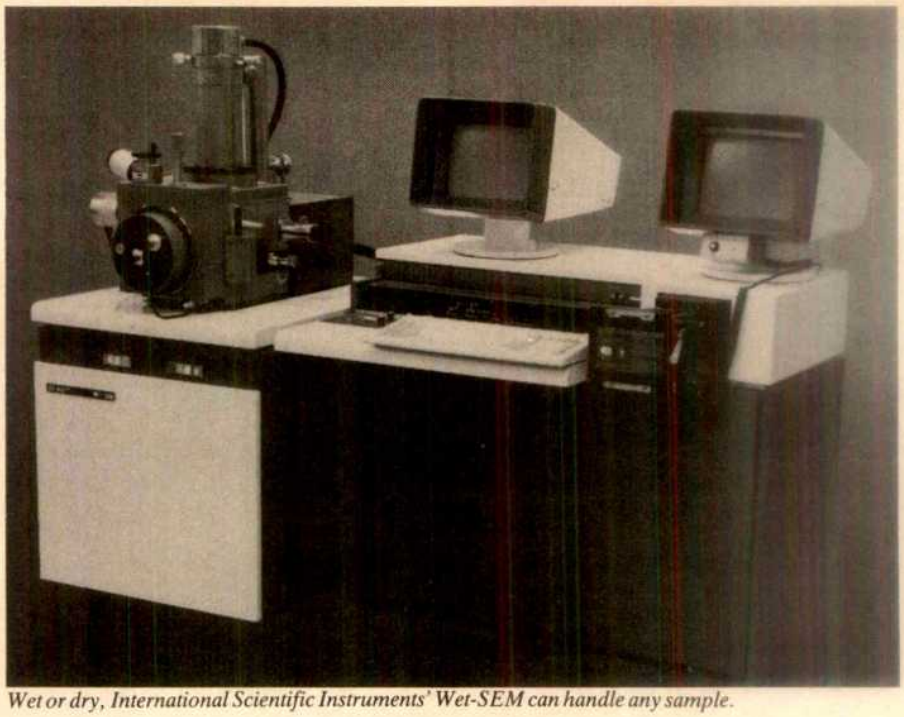
The durable TLC sheets from Analytichem won't crumble during handling.

out for further analysis without resortin to tedious scraping (*Reader Service N 111*). Analytichem's Empore TLC shee were developed with the 3M corporatio and are composed of inert PTFE fibr with chemically bonded silica particle Because the sheets are produced without binder, Analytichem says they can be use in a wide range of applications with opt mum resolution and reproducibility. Th company also says the Empore TL sheets exhibit several times the samp capacity of a standard hard-layer TL plate, preventing problems with ove loading and spot distortion. The 2.5 10 cm and 10 × 10 cm sheets are availab with a variety of bonded silicas.

Enzymes and reagents

Janssen Life Sciences Products has a ne ultra-small **immunogold probe** for incre sed labelling efficiency and penetratic power in the detection of antigens ar biotinylated probes using the immunogo silver staining technique (*Reader Servi No. 112*). The AuroProbe One reage contains colloidal gold particles measu ing 1 nm, and is designed so that the rat between probe protein and gold particle less than one. Because AuroProbe O can be used in a variety of applicatio from immunoblotting to electron micr scopy, it allows results from differe methods to be compared. The signal pr duced by AuroProbe One can be visu ized by silver enhancement usi Janssen's IntenSE reagents for micr scopy and blotting experiments. Ea package of AuroProbe One contains 1 AuroProbe One reagent, 10 ml IGS quality gelatin and detailed instructions

Amersham has recently introduced Multiprime system for **rapid hybridizati** reactions (*Reader Service No. 113*). T new kit is based on Amersham's Mul prime random priming labelling kit, a



allows the synthesis of high specific-activity probes in 30 minutes, and subsequent hybridization with nucleic acid blots in two hours, says the company. The system consists of a DNA labelling kit and a rapid hybridization buffer that increases the hybridization rate without requiring high probe concentrations. Amersham says when using a probe concentration of between 2 and 8 ng nl^{-1}, the sensitivities obtained after a two-hour hybridization are equivalent or higher than sensitivities obtained in an overnight incubation using conventional buffers, without an increase in background.

GIBCO Laboratories has two new **serums** that it says provide an economical and more readily available alternative to fetal bovine serum (*Reader Service No. 114*). GIBCO's supplemented calf serum and calf supreme serum contain defined growth-promoting additives, including vitamins, trace elements, transferrin, insulin, and proprietary growth factors. GIBCO recommends its supplemented calf serum for researchers who experience lot-to-lot variability when using calf serum, and those for whom a high-performance basal calf serum would suffice. The company reports developmental studies indicate that a five per cent supplementation of calf serum in basal medium yields superior results over calf serum, and approaches results with fetal bovine serum. GIBCO says a five per cent supplementation of calf supreme serum in basal medium yields results comparable to fetal bovine serum.

A new version of the Sequenase **DNA polymerase** from United States Biochemical Corporation is now available (*Reader Service No. 115*). Version 2.0 of Sequenase was developed by *in vitro* genetic manipulation of the gene for T7 DNA polymerase which eliminated the exonuclease activity of the enzyme, giving it properties suitable for dideoxy DNA sequencing. US Biochemical says the new version retains all the advantages of the original Sequenase — low gel backgrounds, uniform band intensities, resolution of 600 or more bases, and the ability to use d1TP to remove gel compressions — but also demonstrates increased processivity and reduced pausing at regions of secondary structure. Sequenase Version 2.0 is available in 200- and 1,000-unit packages costing $90 and $355 (US), respectively, or as part of a kit with sufficient reagents for 100 sequences for $185 (US).

Microscopy

International Scientific Instruments has just announced the availability of a **scanning electron microscope** that can be used to examine wet, unprepared samples (*Reader Service No. 116*). ISI's Wet-SEM

Wet or dry, International Scientific Instruments' Wet-SEM can handle any sample.

eliminates the need for sample preparation, such as coating, fixing, dehydrating or critical-point drying. Because the microscope operates in a low-vacuum environment, the $72,500 (US) Wet-SEM can analyse moist specimens or even liquids. The uses of the Wet-SEM span a broad range of applications: it can be used with an optional EDX detector for elemental analysis, or can be switched to a high-vacuum setting for 6-nm resolution. Special features include an automatic focus system and an auto stigmator.

The Electron Microscope Supplies Division of EMCorp has a new **carbon-coater** that it says can deposit a thin film of carbon on specimens for electron microscopy in under two minutes (*Reader Service No. 117*). EMCorp's $3,650 (US) Hummer CDS II comes ready to use right out of the box. It can coat specimens of up to 3.25 inches in diameter, or 12 microscope stubs in a single procedure. Its two-stage direct-drive rotary vacuum pump delivers at least 20 mtorr absolute pressure, and its manual bleed valve introduces argon for processing at 80–100 mtorr. The coater automatically vents once the main power switch is turned off to prevent backstreaming. The Hummer CDS II uses a pre-sharpened dual carbon rod system that EMCorp says yields consistent coating. Particle turbulence in the chamber is prevented by a regulated vent system.

Carbon coating of EM samples in under two minutes by EMCorp.

Leitz Instruments Ltd is now supplying the Narshige range of **micromanipulators and ancillary equipment** with its Labovert and Fluovert inverted microscopes, and its Wild stereomicroscopes (*Reader Service No. 116*). Narshige's pipette puller, microforge, manual and automatic microinjectors, and micro beveller can now be purchased along with Leitz microscopes as a complete micromanipulation workstation which can be configured to suit a wide variety of applications.

Zeiss is bringing the line of **rotary microtomes** made by the German company Microm to the US market (*Reader Service No. 119*). Microm microtomes come in designs for routine paraffin histology, advanced plastics histology and industrial microtomy. Zeiss says the Microm microtomes have backlash-free and maintenance-free roller bearing guideways, enabling them to achieve high precision and stability. Specimen slices between 0.5 µm and 60 µm in thickness are routinely achieved, according to the company. □

These notes are compiled by Carol Ezzell from information provided by the manufacturers. To obtain further details about these products, use the reader service card bound inside the journal. Prices quoted are sometimes nominal, and apply only within the country indicated.

What prospects for the older graduate?

Richard Pearson

Employers have been slow to adjust to the changes in graduate supply. Soon, with decreasing numbers of school leavers, they may have to.

LAST year was the year of the school leaver, or rather concern about the lack of them in the 1990s: as the number of school leavers in the United Kingdom will have declined by 35 per cent over the decade to 1994. With the economy booming and unemployment falling, a shortage of young people will affect employers, trainers and higher education alike (*Nature* **335**, 100; 1988). In the case of higher education the hope is that more mature students can be found who, along with other under-represented groups such as women, ethnic minorities and those from the lower social classes, will, along with a rising participation rate among young people, fill the empty places in higher education and boost the numbers graduating to meet the needs of the economy.

Since the late 1970s there has been growing interest in improving mature students' access to higher education, with more than 400 special access courses being launched to help mature students who lack the standard qualifications for access to higher education. At the same time most institutions now offer applicants aged over 21 selection criteria that do not rely on the normal academic qualifications. Just over half the mature entrants to full-time degree courses lack the traditional entry qualifications, rising to 75 per cent for those entering part-time courses.

Mature numbers

During the past decade the number of mature entrants in higher education has increased by over 50 per cent to total over 186,000 in 1986, driven mainly by the growing number of women and those on part-time courses, the number of men entering full-time university courses rising by only 10 per cent. The overall proportion (aged 21 or over at the time of entry) has now reached over 11 per cent in the universities and 34 per cent in the polytechnics and colleges. The majority of mature students are, however, studying at sub-degree level and on a part-time basis. These older students also have rather different subject preferences to their younger counterparts, with a much higher representation in the humanities and the social sciences, and lower representation in the sciences, technology and engineering.

In addition there is the Open University which was established to meet the needs of the mature, part-time student, many of whom are already in employment. Some 8,000 students graduate each year from the Open University, and of new entrants over 60 per cent are aged 30 or over.

It is worth noting that while in the United Kingdom the mature first degree graduate is still relatively rare, the majority being aged 21–22, this contrasts with the pattern in mainland Europe where courses take longer and many graduates only qualify in their mid to late 20s.

In trying to achieve a further increase in the number of mature entrants, institutions will be facing growing competition from employers for the good mature entrant as both they and higher education seek to make up for the shortfall of school leavers. One important determinant of who wins this battle will be students' responses to loans and the way they trade cash in the hand for potentially higher earnings later in life. One concern, expressed even before the loans proposals were introduced, is the financial barrier facing students taking access courses who were not eligible for mandatory grants. A recent survey of students suggested that half of them would not have started their access courses if the grant had not been available.

What then are the prospects for mature graduates, and will they benefit alongside the traditional young graduate in the booming graduate labour market of the 1990s (*Nature* **334**, 90; 1988)? Looking back to the mid-1980s, when the graduate market was starting to take off, mature graduates were slightly less likely to be in employment and also less likely to be unemployed, with a higher percentage going into further education and training or not being available to work. The latter figure is rather higher still for mature women than for mature men.

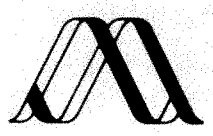
When due allowance is made for subject differences mature graduates had rather better employment rates in education, with little difference being apparent in the case of engineering. In the case of the sciences, administration and business studies, and humanities, they fared rather worse, with both lower employment and higher unemployment rates.

How then are mature entrants treated in the labour market? One problem they face is that many employers, especially in the private sector, structure their recruitment, training and career development programme around the 21 year olds, seeking to get them into management positions by their late 20s. A recent survey has, however, shown that while half of the respondents say they treat all their applicants equally, one in three expressed reservations about applications from mature graduates, with one in five specifying age limits, normally 30 or under, in their recruitment literature. Teaching is a notable exception where positive efforts are being made to attract mature entrants.

Most welcome

More generally the most welcomed were those applicants who had a relevant degree and relevant work experiences, although there was still an age threshold of about 30 after which entry could become more difficult. Much depends on the relevance of the work experience and the job applied for, it being much harder to enter a general training scheme than entering a direct appointment. For those with a non-relevant degree the opportunities were more restricted, reflecting in part the more limited opportunities open to this group of conventional graduates. In general, difficulties increased with age and with the decreasing relevance of qualifications.

The main perceived disadvantages of the mature graduate were their apparent poor mobility, poor adaptability, too high salary expectations, difficulties fitting in with younger peers and not fitting into promotion structures. Given that many companies do not recruit them, it must be assumed that they have a strongly stereotyped picture of them. On the positive side their maturity, stability, commitment and better social and interpersonal skills were often highlighted. Another positive sign for those in their mid-20s is recruiters growing interest in 'second bounce' graduates, those who re-enter the job market quickly after a mistaken first choice.



With the market expected to tighten further into the 1990s only a minority of recruiters when surveyed say they are looking to adjust their policies, despite the fact that mature graduates will be an increasing proportion of those graduating in the future. As with school leavers, most recruiters seem set to carry on with policies appropriate to a time of abundance in the labour market rather than one of stiffening competition. For the mature graduate, economic conditions and skill shortages are going to be the fastest way of breaking down traditional stereotypes.

Richard Pearson is at the Institute of Manpower Studies, Mantell Building, University of Sussex, Falmer, Brighton BN1 9RF, UK.

ANNOUNCING AN IMPORTANT EVENT IN SCIENCE PUBLISHING!

THE MACMILLAN MOLECULAR BIOLOGY SERIES

General Editor: Dr C J Skidmore, University of Reading

MACMILLAN MOLECULAR BIOLOGY

Genetic Elements in *Escherichia coli*

by Dr Peter Smith-Keary

Written for students of molecular genetics and molecular biology, the first volume in the series sets the scene by introducing aspects that provide the scientific background for the major technical advances of genetic engineering. Central topics such as replication, mapping, mutation, transposition and both general and site specific recombination are fully documented.

PB *0333 442687* **£9.95** **HC** *0333 442679* **£25.00**

Organelles

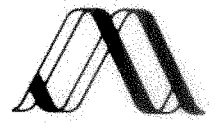
by Dr Mark Carroll

Aimed at second and third year undergraduate students following courses in biochemistry and cell biology, Organelles draws together the latest developments in our understanding of the ultrastructure and function of cell components. Each major cell organelle is the subject of one complete chapter, which ends with self-study questions to focus the reader on central concepts and principles. Throughout the book there are numerous micrographs and line illustrations.

PB *0333 44244X* **£9.95** **HC** *0333 442431* **£25.00** *(February 1989)*

Forthcoming titles include:

What is a Gene? by Dr C J Skidmore
Protein Biosynthesis by Dr R Jagus
The Molecules of the Cytoskeleton by Dr L Amos and Dr W B Amos



Code 355

ORDER FORM

Paperback copies are available on inspection to lecturers in the UK where this may result in an adoption of 12 or more copies. If you would like an inspection copy please indicate in the space provided and return this form to: Inspection Copy Department, Macmillan Education, FREEPOST, Houndmills, Basingstoke, Hants RG21 2BR.

POSTDOCTORAL POSITION

available from April 1989 for a minimum of 2 years to study *in vitro* synaptic physiology and lesion-induced neural plasticity of the vestibular system of lower vertebrates. A background in cellular electrophysiology is required while experience in intracellular recording, in neuropharmacological or in anatomical techniques would be desirable.

Applicants should send a Curriculum Vitae together with letters of recommendation before March 1, 1989 to: **Dr. N. Dieringer, Department of Physiology, Pettenkoferstr. 12, 8000 München 2, West Germany.** (W5721)A

ASSISTANT PROFESSOR (RESEARCH SCHOLAR)

Faculty of Medicine, Department of Physiology, University of Alberta
$32,564–$46,700

Applications are invited for the position of Assistant Professor (Research Scholar) in the area of Renal Physiology. Qualifications include a Ph.D. or M.D. degree and a demonstrated outstanding ability for independent research. The successful candidate will participate in the department's teaching program (both graduate and undergraduate) and other academic activities. The position will depend upon funding through an external agency such as The Alberta Heritage Foundation for Medical Research, and the effective date of employment is dependent upon the success of the application.

In accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada.

Interested applicants should submit their Curriculum vitae, an outline of proposed research, and the names of three referees by January 31, 1989, to:

Dr. P.K.T. Pang, Professor & Chairman, Department of Physiology, University of Alberta, Edmonton, Alberta T6G 2H7

The University of Alberta is committed to the principle of equity in employment. (NW3049)A

DEVELOPMENTAL BIOLOGIST MCGILL UNIVERSITY

The Department of Biology invites applications for a tenure-track position at the Assistant Professor level, effective September 1, 1989. We seek a developmental biologist using cellular, molecular and/or genetic approaches. The successful candidate is expected to establish a strong research program and to participate in teaching developmental biology.

Send curriculum vitae, statement of research interests and goals, representative reprints, and three letters of reference to **Dr. Barid Mukherjee, Chairman, Department of Biology, McGill University, 1205 Avenue Docteur Penfield, Montreal, Quebec, Canada H3A 1B1.** Deadline: February 15, 1989. (NW3048)A

Sandoz Institute for Medical Research

Laboratory Head in Molecular Biology

The Sandoz Institute is seeking an experienced molecular biologist with a good knowledge of cloning methods, preferably in the areas of expression cloning, gene transfer methods and site-directed mutagenesis. The person appointed, who will have at least 3 years' post-doctoral experience, will be in charge of a small group, and will also be expected to play an active role in the overall activities of the Institute, contributing to its long-term drug development goals. He or she should have broad interests in molecular neurobiology, so as to be able to make good use of the collaborative opportunities that the Institute offers. Initially, the emphasis will be on the cloning and characterisation of the bradykinin receptor.

The Sandoz Institute, which opened in 1985, is a multidisciplinary research organization comprising about 60 staff (45 scientific and technical staff) working on a range of neurobiological projects which have as their long-term objective the discovery of new types of analgesic drugs. The Institute is housed in its own premises within University College London, and has strong academic links with the College, though it is administratively and financially independent. The laboratories are modern and well-appointed, and the Institute is well funded by Sandoz Ltd.

The starting salary will be in the range £25,000-£30,000 p.a., and is subject to annual review. A company car, pension scheme, medical insurance, generous holiday allowance and other benefits are included.

Applications, including a full *curriculum vitae* and the names of three referees, should be sent to the Director, Dr. H. P. Rang FRS, Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6BN, UK, Tel: 01-387 4445, by 31 January 1989. Candidates will be welcome to visit the Institute for a preliminary discussion if they wish.

(7992)A

Dyno Particles A.S is a small, expansive high-tech firm with a pronounced pioneering spirit and great international ambitions. The company is a wholly-owned subsidiary of Dyno Industrier A.S., one of Norway's largest chemical companies. The business consists of R&D, production and marketing of products based on Dynospheres®, monodisperse polymer particles. It is our goal to be able to offer the best products of their kind to the world market. Dyno Particles is currently concentrating efforts on the development of products for the chromatographic separation of bio-molecules. In addition, products based on Dynospheres® are presently used in a number of medical and technical applications. The firm is headquartered in Lillestrøm, just outside Oslo. An R&D department is currently being established in the Knivsta-Ar area, between Stockholm and Uppsala.

DYNO PARTICLES IS EXPANDING

In order to reach the high international goals we have set, we seek several competent employees. Persons willing to do their best are invited to join our exciting environment where the challenges are many and the possibilities are great. We place emphasis on cooperation and team spirit as the basis for progress and growth. Therefore, our new employees must have, in addition to in-depth technical expertise, a sense of flexibility and a well-developed ability to work with others.

SECTOR SEPARATION TECHNOLOGY

Sector Separation Technology is responsible for the development and marketing of products for the separation of complex (bio-)chemical mixtures. Our top-priority project involves developing liquid chromatography packings for use in biotechnology-R&D laboratories and the pharmaceutical industry.

The **Marketing Departments** within the Sector have responsibility for marketing and technical service.

The Departments will have great freedom to organize themselves such that the business areas will be as functional and effective as possible. During the current implementation phase, the group will have a strong core-team character. Our products will be of the highest quality and extremely stimulating to work with.

The home base for the business area will be Lillestrøm, but the work will be of a decidely international character involving a great deal of travel. Well-qualified people will be offered highly-competitive salary packages.

Marketing Strategist/Market Researcher

This position will be one of the staff functions and will involve working closely with the Sector's Vice President.

The applicant should have experience in industrial R&D and marketing. Alternatively, the applicant may have experience from a successful industrial new business development. Very strong expertise in the field of biochemical separation technology as well as understanding of the mechanisms behind successful new-technology market introductions are a requirement.

We seek a well-structured candidate with razor-sharp analytical abilities in combination with an open-minded attitude for new technology, ideas and ways of thinking.

Our new Marketing Strategist will be part of a group consisting of the Sector's top R&D and strategic management.

The application is to be marked "DP-1".

Marketing Managers

We are looking for **two Marketing Managers** who will have responsibility for marketing, sales support, and technical service within their respective areas. The applicants should have several years experience in marketing in the separation technology field or associated areas within biotechnology. We assume in-depth background in international marketing as well as a thorough understanding of separation technology.

The new Marketing Managers are expected to be very enterprising persons with the ability to motivate their employees. Being able to work well with others is important because we will be working in groups where open-mindedness and sincerity will be our central principles.

Extremely good working knowledge of English is a requirement; proficiency in other major languages will be a plus.

Marketing Manager – Laboratory Products

In additon to the above qualifications, the new Marketing Manager within this product area should have an R&D background, as well as experience in marketing high-tech laboratory products. A further requirement is a deep insight into the thought processes used in R&D and analytical laboratories, as well as within such divergent environments as universities, R&D institutions, government bodies and industry.

Please mark this application "DP-2".

Marketing Manager – Industrial Products

In addition to the above joint qualifications, the new industrial products Marketing Manager should have good knowledge of, as well as many personal contacts within, the biotechnology or pharmaceuticals industry or both. Direct experience in industrial chromatography will be a plus.

This application is to be marked "DP-3".

Technical Service

For our Department for Industrial Products Marketing, we seek an employee to manage the Technical Service function.

The applicant should have a solid background in applied separation technology, preferably in industrial chromatography of bio-molecules, as well as experience in technical service within the biotechnology or pharmaceutical industry. It will be an advantage to have insight into industrial production and marketing.

Interest in working in close cooperation with the customers, as well as the ability to understand and solve their problems, are of great importance.

The responsibilities will also include arranging training programs for sales personnel and customers. The work will proceed on an international basis and good language abilities, foremost English, will therefore be necessary.

Please mark the application "DP-4".

For more information concerning these positions please contact Kristen Fretheim, 47-2-31-76-81 (Norway), or, Lennart Söderberg, 47-2-31-75-24 (Norway) or 46-18-32-30-62 (Sweden).

Please deliver your application by 26th January to DYNO INDUSTRIER A.S., Chemicals Group, P.O. Box 160, N-2001 Lillestrøm, Norway.

DYNO

The Wellcome Trust

Scientific Officer

The Wellcome Trust wishes to appoint a scientific officer to assist Dr. L. H. Smaje, Assistant Director in the administration of the Trust's programme in Physiology and Pharmacology.

This permanent position will involve processing grant applications, production of background policy papers and interfacing between the scientific community and the Trust.

The salary will initially be within the range £17,611 - £21,701. (Starting salary will be dependent upon age and experience.) Other employment conditions, including a non-contributory pension scheme, are excellent.

Candidates with several years' post doctoral research experience and a broad interest in science and medicine are invited to send a **curriculum vitae** and covering letter explaining why they are interested in a career in research administration to:

Deirdre Carty, The Wellcome Trust, 1 Park Square West, London NW1 4LG. Tel: 01-486 4902.

Informal enquiries are welcome and potential applicants are invited to telephone Dr. Smaje on the above number.

The closing date for applications is 18th February 1989.

(8004)A

ACADEMIC GASTRO-ENTEROLOGIST/ HEPATOLOGIST

to join a new investigative unit. Applicant must have strong background in basic research (immunology, cell biology, virology or liver injury desirable). Level of academic appointment is based on experience and qualifications. **Dr. George B. McDonald, Division of Clinical Research (M246), Fred Hutchinson Cancer Research Center, 1124 Columbia Street, Seattle, WA 98104.** An equal opportunity/affirmative action employer. (NW3057)A

Post Doctoral Fellow/ Research Associate

To examine the roll of Protein Kinase C in mediating the growth and differentiation of hematopoietic cells. Studies will focus on the control of transcription by the interaction of PK-C with the jun oncogene. Please send CV and names of three refs. to **Dr. A. Kraft, Div. of Hem/Onc, Univ. of Alabama at B'ham, 513 THT, 1900 Univ. Blvd., B'ham, AL 35294.** (NW3071)A

PLANT MOLECULAR BIOLOGY, TOULOUSE — FRANCE

GROUP LEADERS

The Laboratoire de Biologie Moléculaire des Relations Plantes-Microorganismes CNRS-INRA in Toulouse is seeking to recruit two Group Leaders. The laboratory is located close to the Toulouse University campus, the second largest in France for Science and Technology. At present there are nine groups working on the molecular genetics either of the *Rhizobium*-legume symbiosis or of plant diseases caused by bacteria or viruses. The laboratory is to be enlarged in 1989 and two permanent positions for senior scientists will be created.

The appointees will have to develop groups working on plant genes involved in plant-microbe interactions. Excellent scientific credentials and at least four years of post-doctoral research experience in cellular molecular biology are required.

Annual salary will be in the range FF 150,000-200,000 depending on qualification and experience.

Further information may be obtained from **Dr. Georges Truchet, Laboratoire de Biologie Moléculaire, CNRS-INRA, BP27, 31326 Castanet-Tolosan Cedex, France,** to whom applications including a CV and the names of 3 referees should be sent. Closing date 28 February, 1989. (W5708)A

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF BIOCHEMISTRY AND GENETICS

POSTDOCTORAL RESEARCH ASSOCIATESHIPS IN MOLECULAR BIOLOGY

Applications are invited for three postdoctoral positions:

(1) Location of antibody neutralisation sites in Newcastle disease virus. This work, currently in progress, involves sequence analysis of monoclonal antibody resistant mutants with a view to the development of an improved vaccine against fowl pest. (Supported by the Agricultural and Food Research Council until February 16 1990).

(2) Expression, purification and characterisation of the RNA dependent RNA polymerase of Newcastle disease virus. This 250 KDa protein is present in only low amounts in the virus and infected cells. We have cloned and sequenced the gene and propose to overexpress it and purify the enzyme. We then propose to study the mechanism of action of the pure enzyme in replication and transcription *in vitro*. (Supported by a new three-year grant from the Wellcome Trust.

(3) The RecBCD protein of *E. coli*: role of the RecD subunit. We have previously cloned and sequenced the *recB, recC* and *recD* genes which are involved in DNA repair and genetic recombination. We are presently investigating the interaction of purified RecB, RecC, RecD and RecBCD proteins on model DNA substrates *in vitro*. (Supported by a new three-year grant from the Medical Research Council).

Candidates for all positions should ideally have experience of recombinant DNA techniques. Additional experience with tissue culture techniques would be advantageous for project (1) and preparative enzymology for projects (2) and (3). Starting salary will be up to £11,680 (plus superannuation) on the 1A scale.

Applications including a full *curriculum vitae* and the names and addresses of two academic referees should be sent to **Prof. Peter T. Emmerson, Department of Biochemistry and Genetics, The Medical School, University of Newcastle upon Tyne, NE2 4HH, UK.** (7996)A

FACULTY POSITION IN PROKARYOTIC GENETICS

The Department of Biology at Texas A&M University invites applications for a tenure-track position in bacterial or bacteriophage genetics and molecular biology. Candidates should be using a prokaryotic organism to study fundamental biological problems. Special consideration will be given to applicants interested in developmental, regulatory or membrane systems. Essential qualifications include a strong record of research accomplishment, the ability to develop a vigorous research program, and a commitment to training undergraduate and graduate students. The Department has excellent research facilities and will provide competitive salaries and startup funds. Please send curriculum vitae, a statement of research interests, and the names, addresses and telephone numbers of at least three references by February 15, 1989, to:

Dr. Michael D. Manson
Chairman, Microbiology Search
Department of Biology
Texas A&M University
College Station, TX 77843

Texas A&M University is an Affirmative Action/Equal Opportunity Employer. Minority candidates are especially encouraged to apply.

(NW3061)A

UBC

The University of British Columbia

Biotechnology Laboratory

Fermentation, Process Engineering and Bio-Instrumentation

The University of British Columbia has recently initiated the Biotechnology Laboratory under the directorship of Dr. Michael Smith. Its objective is to foster an interactive approach to problems in biotechnology. A total of ten new tenure track positions are being filled during 1987-89. Appointments will be primarily at the rank of Assistant Professor. Applicants must have a Ph.D. degree. Post-doctoral experience is an asset. Successful candidates will be expected to develop their own vigorous research programs and to collaborate with other faculty members on problems in one of the following areas: human, animal, plant and forest biology and in fermentation and process engineering and bio-instrumentation (with special emphasis on mammalian cell culture and the production of specific proteins) and in the application of genetic engineering techniques to these problems. Substantial start-up funding will be provided. Faculty appointed to the Biotechnology Laboratory will have a joint appointment in an appropriate academic Department and will teach and supervise undergraduate and/or graduate students in that Department's programs or in academic programs to be established under the aegis of the Biotechnology Laboratory. At this time, candidates are sought with research expertise in the following area:

Bio-Instrumentation *(1 position)*. Monitoring and control of bioreactors and purification processes. Development of biosensors and measuring circuits. The applicant should have the ability to collaborate with biochemistry and electrical engineering faculty members and students, and to develop a teaching program bridging these disciplines.

Process Engineering *(1 position)*. Development of upstream and/or downstream processing techniques relevant to the purification of biologicals. The applicant should be experienced in the application of genetic engineering principles, in modern purification procedures for complex biomolecules and be capable of developing a teaching program bridging the areas of genetic and process engineering.

Appointments will be made starting 1st July 1989 or as soon as possible thereafter. Closing date for applications, 1st February 1989. Salary will be commensurate with qualifications and experience. The University of British Columbia offers equal opportunity for employment to qualified female and male applicants. In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada.

Applications, including a full c.v., plans for future research (approximately 2-3 pages), and the names, addresses and phone numbers of three references, should be sent to: **Mrs. Darlene Crowe, Administration, Biotechnology Laboratory, The University of British Columbia, Room 237 - 6174 University Boulevard, Vancouver, B.C., Canada V6T 1W5.**

NW(2887)A

POSITIONS AVAILABLE 1988-89

The School for Field Studies seeks Senior and Associate faculty for semester and summer programs in the following specialties: Tropical Species Diversity/Australia; Ethnobotany/Ecuador; Landscape Ecology/Colorado; Tropical Ecology/Costa Rica; Acid Rain/Adirondacks; Wildlife Management/Kenya; Cultural Ecology/Himalayas; Bald Eagles/Alaska; Coral Reef Ecology & Marine Parks Management/Virgin Islands; Monkseals/Greece; Endangered Monkeys/Mexico; Spinner Dolphins/Hawaii; Humpback Whale Ecology/North Atlantic; Bottlenose Dolphins/Alabama. SFS also seeks applicants for administrator/teachers to direct permanent Centers for Rainforest Studies/Australia; Marine Ecosystem Studies/Virgin Islands (coral reefs); Wildlife Management Studies/Kenya (big game ecology); and Marine Mammal Studies/Baja, Mexico (whale ecology).

QUALIFICATIONS: excellence in teaching; advanced training in environmental sciences/conservation (Ph.D for Senior Faculty, Master's degree for Associate Faculty; leadership and facility with group dynamics; commitment to experimental education; experience in field research situations; teamwork; and administrative ability (for Field Directors). Please submit cv and letter of interest and qualifications to the **Dean, School for Field Studies, 16 Broadway, Beverley, MA 01915 (phone (508) 927-7777; FAX (508) 927-5127)).** (NW3066)A

Cird
Centre International de Recherches Dermatologiques

SOPHIA ANTIPOLIS – VALBONNE

RECRUTE

UN CHERCHEUR EN PHARMACOCINETIQUE ET METABOLISME (H, F) DOCTORAT, Ph.D. ou équivalent

Le CIRD est un Centre de Recherches International, situé dans le Sud-Est de la France, qui a pour vocation la recherche de nouveaux produits destinés au traitement des maladies de la peau.

Le poste sera rattaché au département de Biopharmacie, dans le groupe de pharmacocinétique et métabolisme. Son titulaire aura pour fonction principale:

la responsabilité de ses travaux de recherche, qui seront plus particulièrement orientés vers le domaine de l'identification des métabolites de nouveaux produits pharmaceutiques.
Il sera amené à utiliser des techniques telles que spectrométrie de masse et HPLC.

Il sera par ailleurs impliqué dans l'ensemble des activités du groupe.

Le candidat doit avoir une bonne connaissance pratique des méthodes avancées, d'analyse des produits dans les milieux biologiques, et d'identification des métabolites.

Une à deux années d'expérience post-doctorale sont souhaitées.

Ce poste demande une réelle capacité de communication et d'interaction avec les membres du groupe et les scientifiques du Centre.

Il implique par ailleurs une réflexion et une démarche intégrant les règles des "bonnes pratiques de laboratoire".

ADRESSER C.V. + LETTRE MANUSCRITE + PHOTO (sous référence 88-10/07) AU SERVICE DU PERSONNEL – C.I.R.D. – SOPHIA ANTIPOLIS – ROUTE DES LUCIOLES – 06560 VALBONNE FRANCE. (W5720)A

CHIEF SCIENTIFIC OFFICER

The Imperial Cancer Research Fund (ICRF) Laboratories in the Institute of Molecular Medicine, John Radcliffe Infirmary, Oxford are due to open in the spring in 1989.

The fund is seeking a Chief Scientific Officer to coordinate and run the technical support services for the laboratories.

The ICRF Laboratories will initially occupy 7,000 sq. ft. with expansion to 9,000 sq. ft. in the future. They will be largely self sufficient with common instrument rooms and service areas. There will be a number of independent research groups with differing but related interests. The number of staff will be approximately 18 in the first instance, increasing to 40 in 1989, and 55 in 1990 to a maximum of around 70 at full complement.

As a member of the Central Research Division, the Chief Scientific Officer will be reponsible for the day to day administration of the laboratory services.

Applicants should be qualified to degree level (or equivalent) in a scientific subject and should possess substantial experience of laboratory administration. Ability to organise own work and act with a degree of independence. Age 30+.

Salary range £14,584 to £17,145.

For further information and application form please write or telephone Mrs P. Harwood, Recruitment Officer, Imperial Cancer Research Fund, PO Box 123, Lincoln's Inn Fields, London WC2A 3PX, on 01-242 0200 ext. 2357 quoting ref 45/R.

Smoking is actively discouraged. (8024)A

IMPERIAL CANCER RESEARCH FUND

KING'S COLLEGE LONDON
Department of Biochemistry

Two Postgraduate/Postgraduate Research Positions (Chemists/Biochemists/Pharmacologists)

1) THE ROLE OF OXIDANTS IN HUMAN ATHEROSCLEROSIS

Applications are invited for the position of post-doctoral scientist to participate in a study of the role of oxidants in human atherosclerosis (two years in the first instance). The work will be based in the laboratory of Professor B Halliwell, but occasional trips to Cambridge will be necessary to collect human clinical material. Candidates should have a first degree and a PhD in Chemistry, Biochemistry or Pharmacology. Good experience of analytical methods, particularly HPLC and GC-mass spectometry, would be advantageous. Salary in range £9,865-£12,150 plus London Weighting (currently £1,650).

Applications including a full CV and the names of two referees should be sent as soon as possible to **Professor B Halliwell, Department of Biochemistry, King's College London, Strand, London, WC2R 2LS, UK.**

2) THE ROLE OF NEUROTOXINS IN PARKINSON'S DISEASE

This position is supported by the Parkinson's Disease Society (two years in the first instance) and is concerned with potentially neurotoxic natural products. Good experience in analytical methods, particularly HPLC, would be advantageous. Salary in the range £10,315-£11,515 including London Weighting.

Applicants including a full CV and the names of two referees should be sent as soon as possible to **Dr P B Nunn, Department of Biochemistry, King's College London, Strand, London WC2R 2LS, UK.** (8008)A

ANNOUNCEMENT

Recruitment of Executive Director

The International Union Against Cancer, a non-governmental organization, wishes to recruit an Executive Director for its secretariat in Geneva.

Applicants should be knowledgeable in medical affairs, especially in the field of cancer and preferably in the international field. Experience in administration and financial management will be an advantage. A pleasant and diplomatic character trait would be helpful in our fund raising activities.

Languages: fluent English and a good working knowledge of French are expected.

Date of engagement will be decided by mutual agreement.

Applications with a curriculum vitae (photograph), photocopies of diplomas and degrees, and the names of two referees should be sent to:

Dr. Max. M. Burger
International Union
Against Cancer
3, rue du Conseil-Général
CH-1205 Geneva
(W5713)A

DYSON PERRINS LABORATORY

Postdoctoral Positions in Protein Studies

Applications are invited for two postdoctoral positions supported by an SERC grant to study protein protease inhibitors. One person will be involved in the synthesis, expression and site directed mutagenesis of genes in yeast or *E. coli*, and the other will be concerned with the isolation of the heterologous proteins and study of their inhibitory properties. Applicants must be familiar with either recombinant DNA techniques or have experience in protein isolation and enzyme kinetics.

The positions are available from 1 April 1989 for up to three years, but persons who would be available by 1 October 1989 including those in their final Ph.D. year are invited to apply. The salary will be on the Research Staff Grade 1A scale.

Applicants should send their *curriculum vitae*, and ask 2 academic referees to write on their behalf to Dr. G. Lowe FRS, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY (8009)A

POSTDOCTORAL POSITION

available spring 1989 to study in brain slices, serotonergic responses mediated by receptors postsynaptic to raphe neurons with special reference to hallucinogenic drugs. Experience with electrophysiological techniques required. Send curriculum vitae and names and addresses of three references to: **Dr. Joseph Goldfarb, Department of Pharmacology, Box 1215, Mount Sinai School of Medicine, One Gustave L. Levy Place, New York, NY 10029-6574.**

An Equal Opportunity Employer. (NW3054)A

CAMBRIDGE UNIVERSITY
VISUAL SCIENCE

Applications are invited for a two-year post-doctoral position for interdisciplinary research on the polymorphism of colour vision in primates and man. Postgraduate experience of electrophysiological recording would be preferred, but pre-doctoral candidates and candidates with training in other areas of visual science will be considered. The research is MRC-funded and is in collaboration with Dr. J. Bowmaker, Queen Mary College, University of London. Contact **Dr. J. Mollon, Department of Experimental Psychology, Downing St., Cambridge, CB2 3EB.** (8011)A

Chemical Toxicologists

London

You will be working in a combined medical and scientific division which is responsible for providing advice to the public and Government departments on potential hazards to health from environmental radiation and from chemical substances in food, drinking water, consumer products and the environment.

One post offers an opportunity to work on the safety evaluation of food additives and contaminants, currently an area of considerable public interest. The job involves assessing a wide variety of toxicological studies, giving a broad basis of all round experience in the science.

The other post offers an opportunity to work on the chemical contamination of drinking water and the environment. The work involves evaluation of toxicological and epidemiological data in an area where there is rapidly growing public, political and scientific interest.

Both posts involve work in the general area of regulatory toxicology, and post holders will make a wide range of contacts and will be closely involved with the scientific basis of regulatory decision making. The posts therefore provide an appropriate step in a wide range of careers.

You should have a 1st or 2nd class honours degree in a relevant science discipline and must have at least 2 years' experience in toxicology and/or environmental sciences.

Salary is in the range £12,255–£15,745 with further increments, depending on performance, up to £18,125 (including an Inner London Weighting of £1750).

For further details and an application form (to be returned by 20 January 1989) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 468551 (answering service operates outside office hours).

Please quote Ref: SB/21/KE.

EVOLUTIONARY BIOLOGIST

EMORY UNIVERSITY, Department of Anthropology and Department of Biology, seek two joint positions in evolutionary biology. Candidate's research may be in any aspect of evolutionary biology. Ability to interact effectively with faculty in both Anthropology and Biology programs essential. Both positions are tenure track at the assistant professor level; for exceptional candidates, appointment as associate or full professor possible. Successful candidates must have a strong research record and a commitment to quality teaching. Review of applications will begin January 16, 1989. Send *curriculum vitae* and names and references to:

Peter J. Brown and Gray Crouse, Search Committee Chairs, Department of Anthropology, Emory University, Atlanta, GA 30322.

Emory University is an affirmative action/equal opportunity employer.
(NW3045)A

THE UNIVERSITY OF UTAH
Postdoctoral Fellow/Research Associate in Neurobiology

A position for a Postdoctoral Fellow or Research Associate in Neurobiology is currently available. Supported by an NIH grant through 1993, the project is studying interactions between axons and their target neurons in the developing auditory nervous system (see *Curr. Top. Develop. Biol. 21*:309-340, 1987). The project involves experimental embryology tissue culture, recording from and labeling neurons in brain slices, pharmacophysiology, and morphometric analyses. Experience in electrophysiology or tissue culture of neurons is desirable. The position offers competitive salary and benefits. The University of Utah is an equal opportunity employer. Please send a CV and the names of three evaluators to: **Dr. T. N. Parks, Department of Anatomy, University of Utah School of Medicine, Salt Lake City, UT 84132.** (NW3074)A

Department of Geology
University of Alberta

Applications and nominations are invited for a Professorship in the area of Experimental Igneous Petrology. The Department of Geology is a well-equipped research oriented department in the Faculty of Science. The successful candidate will be responsible for supervising a research facility which includes a uniaxial, split-sphere USSA apparatus ("Superpress") a piston cylinder apparatus, and internally heated, gas pressure vessel and cold seal bombs.

We are seeking a candidate with excellent leadership qualities, an outstanding research record, and a dedication to teaching at the graduate and undergraduate level.

The position is now available with the appointment salary and rank commensurate with experience. Applications or nominations, including a detailed *curriculum vitae*, a brief statement of teaching and research interests, and the names of three referees, should be received by March 1, 1989 and addressed to:

Dr. N. W. Rutter, Chairman
Department of Geology
University of Alberta
Edmonton, Alberta, Canada
T6G 2E9

The University of Alberta is committed to the principle of equity in employment but, in accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada. (NW3050)A

RMIT AN EQUAL OPPORTUNITY EMPLOYER

PRINCIPAL LECTURER

MEDICAL LABORATORY SCIENCE

AUSTRALIA

The Department of Applied Biology is a multi-disciplined department within the Faculty of Applied Science.

The appointee will be one of three (3) Principal Lecturers in the Department and be responsible to the Head of Department for co-ordinating the under-graduate and post-graduate degree courses in Medical Laboratory Science. In addition he/she will be involved in the general academic and administrative activities of the Department. It is expected that the appointee will teach and undertake research in his/her discipline and will be involved in collaborative industrial projects.

Applicants should possess an appropriate tertiary qualification to doctoral level. Teaching, medical diagnostic laboratory and research experience are essential. Some industrial and managerial experience is highly desirable.

Salary: $A49,704 p.a. **Ref:** 122/21/A.

Further information may be obtained from Dr R. Borland, Head of Department, on (61-3) 660 2612.

SENIOR LECTURER IN PATHOLOGY

The Department of Applied Biology is seeking a graduate in medical or veterinary science with appropriate post-graduate qualifications and clinical experience in pathology. Teaching and research experience would be desirable.

The successful applicant will have responsibility for teaching General Pathology and Special Pathology to second and third year undergraduates respectively in the Bachelor of Applied Science (Medical Laboratory Science) programme. In addition, the appointee will be expected to contribute to the coursework Master of Applied Science degrees in Applied Toxicology and in Clinical Laboratory Science.

Salary Range: $A40,937-$47,564 p.a. **Ref:** 122/25/A.

Further information may be obtained from Dr R. Borland on (61-3) 660 2612.

Phone Personnel Services on (61-3) 660 2337 for a Position Description. Written applications quoting relevant reference number should be addressed to The Senior Appointments Officer by 10 February, 1989. (W5707)A

ROYAL MELBOURNE INSTITUTE OF TECHNOLOGY LIMITED
GPO Box 2476V, Melbourne, Vic. 3001

SENIOR MOLECULAR BIOLOGIST

Lactic acid bacteria

A senior scientist with a proven record of innovative research in microbial genetics is offered a position on a project titled "The genetics of the genus Bifidobacterium". The succesful applicant will join a newly established group at the Danish Government Research Institute for Dairy Industry working on the genetics of lactic acid bacteria. Supervision of graduate (Ph.D.) work on projects associated with the appointee's own research is part of the job profile. In this respect the position is a guest professorship at **The Technical University of Denmark.**

The position is a two year research appointment administered by the government funded "Centre for Food & Process Biotechnology". Applications are requested as soon as possible and immediate appointment in the position is preferred.

The annual salary will be approx. US $ 30,000 — according to experience. In addition to the salary, a four-room modern flat will be offered.

Applications, including c.v., should be sent to:

Professor, Dr.techn. John Villadsen,
Director
Centre for Food & Process Biotechnology
Dept. of Biotechnology, Block 223
Technical University of Denmark
DK — 2800 Lyngby.
Tel: +45–2–88 40 66
Fax: +45–2–88 22 39

The Centre for Food & Process Biotechnology consists of 27 research projects and administers a grant equivalent to approximately US $ 8 mio.

The Danish Government Research Institute for Dairy Industry is at the town of Hillerød, 35 km north of the centre of Copenhagen.

(W5709)A

KUWAIT INSTITUTE FOR SCIENTIFIC RESEARCH

Kuwait Institute for Scientific Research (KISR) is a nonprofit organization with a staff of more than one thousand employees engaged in applied research in the fields of environmental and earth sciences; water resources; food resources; engineering; petroleum, petrochemicals and materials; and techno-economics.

KISR has a vacancy for a:

DATE PALM TISSUE CULTURIST

● Major Duties

— Developing plant tissue culture methodology for micropropagation research on date palms, with eventual inclusion of other plant species.
— Supervising and coordinating plant tissue culture laboratory activities and providing training in plant tissue culture methodology.
— Optimizing micropropagation systems for ultimate commercial application.
— Conducting intensive plant research including nutrition, metabolism, and environmental tolerance.
— Overseeing and guiding greenhouse acclimation and establishment of micropropagated plants.

● Qualifications

Applicants should have a Ph.D. in one of the basic plant sciences (Botany, Breeding, Physiology) with emphasis on tissue culture and/or advanced molecular genetics and its application in developing new cultivars. Strong background in plant physiology is an advantage. Five or more years of research experience in tissue culture with documented expertise in date palm tissue culture (somatic embryogenesis and/or organogenesis) as well as use of somaclonal variation in developing stress tolerant crop plants. Working experience overseas is an advantage.

KISR offers attractive tax free salaries commensurate with qualifications and experience and generous benefits that include gratuity, free furnished air-conditioned accommodation, school tuition fees for children, contribution to a savings plan, six weeks annual paid vacation, air tickets, free medical care and life insurance.

Interested applicants are requested to send their Curriculum Vitae with supporting information not later than one month from the date of this publication, to:

Director General, Kuwait Institute for Scientific Research
P.O. Box 24885 Safat, 13109 Safat — KUWAIT.

(W5711)A

The French National Center for Scientific Research (C.N.R.S.) is recruiting 609 researchers.

Applications to be received until 31 January 1989 at 6 pm [required level thesis].

Applications can be withdrawn before 31 January.

The best in every discipline will be shortlisted.

Enquiries about the different disciplines, positions and locations can be obtained from:

IRF
Institutet för rymdfysik
Swedish Institute of Space Physics

VISITING REMOTE SENSING SCIENTIST MICROWAVE SCATTERING STUDIES

The Swedish Institute of Space Physics (formerly known as the Kiruna Geophysical Institute) invites applications for a post-doctoral research position. The position is a time-limited one and will be available during the leave of absence of the head of the Radio Remote Sensing group, initially for a duration of six to twelve months, starting July 1, 1989. An extension may become possible.

The successful applicant will be a member of our team for microwave scattering studies. This was established about three years ago as a part of the national effort in support of the ESA ERS programme. During the next few years, emphasis will be put on experimental scattering and cross section studies of the land and vegetation typical of Northern Scandinavia and the interpretation of data in terms of scattering models as well as operational SAR signatures. Frequent co-operation with other groups engaged in SAR and microwave remote sensing is anticipated. He/she is also expected to provide scientific guidance to the junior members of the group in his/her fields of expertise.

The Institute seeks applications from highly motivated and creative individuals with several years' experience in the microwave remote sensing field. A background in SAR techniques is desirable and experience with polarimetry methods would be an advantage. Interested candidates should send an application with curriculum vitae, list of publications and names of three professional references to **Professor Bengt Hultqvist, Swedish Institute of Space Physics, P.O. Box 812, S-981 28 KIRUNA, Sweden,** before April 1, 1989. (Phone + 46-980-12240, Telex 8754 IRF S, Telefax +46-980-15465). The salary level depends upon experience and qualifications, starting from around SEK 16,000/month (corresponding to US $ 32,000/year).

The Swedish Institute of Space Physics is a separate Government agency and an equal opportunity employer.

Public Service Commission of Canada | Commission de la Fonction publique du Canada

Research Scientist

Canadian Forestry Service
Northern Forestry Centre
Edmonton, Alberta

We require a molecular geneticist to initiate, develop and conduct research in molecular genetics using recombinent DNA technology, gene fusion and gene transfer in both pro- and eucaryotic organisms. The work involves analysis, interpretation and reporting of investigations at the scientific and technical report level and interaction and communication with other scientists from a variety of organisations.

You require a Ph.D. in Molecular Genetics or Biochemistry with several years of related experience preferably in Eucaryotic Systems and demonstrated ability to plan and conduct research, prepare scientific reports and communicate effectively.

Knowledge of English is essential.

We offer a salary commensurate with your qualifications and experience.

The Northern Forestry Centre is the western and northern regional office of the Canadian Forestry Service. Work will actually be conducted at the Plant Biotechnology Centre, University of Alberta under the guidance of Dr. A.A. Szalay.

For further information, please contact either Dr. S. Malhotra, Northern Forestry Centre, 5320-122 Street, Edmonton, Alberta, Canada, T6H 3S5; Phone (403) 435-7201, or Dr. A.A. Szalay, Department of Cell Biology, Medical Sciences Building, University of Alberta, Edmonton, Alberta, Canada, T6G 2H7; Phone (403) 450-5327.

Forward your résumé and/or application form and the name of three references to:
John Taylor
Agriculture Canada
Personnel Branch
Room 227, Sir John Carling Bldg.
Ottawa, Ontario, K1A 0C5
Please Quote: 88-RES-62

Closing date: January 27, 1989
Personal information you provide is protected under the Privacy Act. It will be held in Personal Information Bank DOA/P-SE-902, Personnel Selection files.

Tufts University, School of Medicine

POST DOCTORAL POSITION

Post doctoral position available immediately for Molecular Biologist/Biochemist to study transcription and translation factors regulating ferritin synthesis in normal and diseased states. Available for up to 3 years. Please send CV and letters of recommendation to

Dr. Jim Drysdale,
Dept. of Biochemistry,
TUFTS UNIVERSITY,
School of Medicine,
136 Harrison Ave.,
Boston, MA 02111.

(NW3078)A

Faculty Position in Soil Science

The School of Forestry & Environmental Studies at Yale University invites applications for a faculty appointment, at the Assistant Professor level, in soil science. Applicants should have a doctorate in some aspect of soil science. Teaching responsibilities will include a comprehensive, masters level course in soil science for natural resource management, and one or more advanced graduate courses. Research interest in forest soils or soils of other natural communities is especially appropriate. Specific focus, however, could be in the physical, chemical, or biological aspects of soil science.

To apply, send a letter stating teaching and research goals, a curriculum vitae and transcript, the names addresses, and phone numbers of three references, and examples of recent work to: **Prof. William H. Smith, Soils Search Chair, Yale University, School of Forestry & Environmental Studies, 370 Prospect Street, New Haven, Connecticut 06511, phone: (203) 432-5149.** A complete application packet should arrive no later than March 1, 1989 and is for an initial term of three years.

Yale University is an Equal Opportunity/ Affirmative Action Employer

(NW3072)A

CYTOGENETICIST, MASSACHUSETTS GENERAL HOSPITAL

We invite applications for a staff position in cytogenetics. Applicants should have a Ph.D. or M.D. degree, experience in cytogenetics (preferably with certification in clinical cytogenetics), a strong background in molecular biology, and research accomplishments. The person appointed will be Associate Director of the Cytogenetics Laboratory at the MGH and Assistant or Associate Professor of Pathology at Harvard Medical School. Send curriculum vitae and the names of three persons from whom recommendations can be solicited to

Dr. Robert T. McCluskey,
Department of Pathology,
Massachusetts General Hospital,
Boston,
MA 02114.

The Massachusetts General Hospital and Harvard Medical School are Affirmative Action/Equal Opportunity Employers. (NW3042)A

RESEARCH ASSOCIATE

To conduct research on the broad and specific respiratory controls of gene expression in *Escherichia coli*. The work will require knowledge and experience in enzymology, membrane biochemistry, intermediate metabolism, bacterial genetics, and various techniques of in vitro and in vivo recombinant DNA technology.

At least 3 years of postdoctoral experience with high quality of published work required.

Annual salary $32,000 plus benefits. Submit cv and names of three references to the **Division of Employment Security, Hurley Bldg., Government Center, Boston MA 02114,** and refer to job reference number 9262. (NW3064)A

ASSISTANT PROFESSOR MOLECULAR NEUROBIOLOGY UNIVERSITY OF FLORIDA COLLEGE OF MEDICINE

A tenure tract assistant professor position is available in the Department of Neuroscience starting on or before July 1, 1989. The University has a large and growing state-funded Interdisciplinary Center for Biotechnology Research and, together with the Department of Neuroscience, has a strong commitment to expand molecular biology research. The successful candidate will be expected to establish an independent research program and participate in graduate/medical teaching. Send a summary of research interests, curriculum vitae and three letters of recommendation to: **Dr. Gerry Shaw, Department of Neuroscience, University of Florida College of Medicine, Gainesville, FL 32610-0244,** before March 1, 1989.

The University of Florida is an equal opportunity/affirmative action employer. (NW3076)A

DIRECTOR, WISCONSIN REGIONAL PRIMATE CENTER

The University of Wisconsin-Madison announces a search for Director of the Wisconsin Regional Primate Center. The Director will be expected to lead development of strong research programs involving University Faculty and Staff and outstanding visiting researchers in important biomedical areas in which the non-human primate offers unique opportunities for endocrinological, reproductive and behavioural research relevant to the health of man and other primates. The director will also hold a tenured professorship in an appropriate academic department and will have the opportunity to continue his/her research and graduate student/postdoctoral training. Applicants should supply a full curriculum vitae, a statement of research interests and names of three references no later than February 1, 1989.

Address correspondence to Primate Director Search Committee, 333 Bascom Hall, University of Wisconsin-Madison, Madison, Wisconsin 53706.

The University is an equal opportunity/affirmative action employer. (NW3086)A

UNIVERSITY OF SURREY
DEPARTMENT OF MICROBIOLOGY
RESEARCH IN MOLECULAR VIROLOGY
RE-ADVERTISEMENT

A research post funded by Action Research for the Crippled Child is available for up to three years to study the molecular biology of rubella virus.

We are looking for a post-doctoral scientist, preferably with experience and a continuing interest in virology, although a suitably qualified graduate will be considered.

The successful applicant will join Dr P G Sanders' group at Surrey in a collaborative study with Dr J Best and colleagues at St Thomas' Hospital, London.

The post is available immediately and the starting salary will be up to £11,680 pa. Starting salary will depend on age, experience and qualifications and superannuation will be under USS conditions. For further details contact Dr P G Sanders on (0483) 571281 ext 2665.

Applications in the form of a Curriculum Vitae (3 copies) including the names and addresses of two ref erees, should be sent to the **Personnel Officer (JLG), University of Surrey, Guildford, Surrey GU2 5XH,** by 27th January 1989 quoting the reference number:: 797N.

Previous applicants for post number 755 are still under consideration. (8015)A

Faculty Position in Geographic Information Systems

The School of Forestry & Environmental Studies at Yale University invites applications for a faculty appointment, at the Assistant Professor level, in geographic information systems. Applicants should have completed their doctorate by the date of appointment in a relevant field such as Forestry, Geography, Geology, Remote Sensing, Landscape Architecture, Ecology, or Computer Science. Teaching responsibilities will include a comprehensive, masters-level course in GIS for natural resource management, and one or more advanced graduate courses. Research interests in applications or development of GIS for interdisciplinary natural resource management are preferred. Opportunities for collaborative work in parallel computation exist with the Department of Computer Science. To apply, send a letter stating teaching and research goals, a curriculum vitae and transcript, the names, addresses, and phone numbers of three references, and at least one example of recent work (e.g., reprints, manuscripts, or research proposals) to: **Prof. Clark S. Binkley, GIS Search Chair, Yale University, School of Forestry & Environmental Studies, 205 Prospect Street, New Haven, Connecticut 06511, phone (203) 432-5136.** A complete application packet should arrive no later than March 1, 1989. The position is available July 1, 1989 and is for an initial term of three years.

Yale University is an Equal Opportunity/Affirmative Action Employer (NW3083)A

UNIVERSITY OF MICHIGAN
Department of Geological Sciences

Postdoctoral Research Assistantship in Radiogenic Isotope Geochemistry

Applications are invited for a 3-year position (subject to renewal) funded by the University of Michigan. Candidates should have experience in Nd, Sr or Pb isotope geochemistry and thermal ionisation mass spectrometry.

Instrument Analyst in Radiogenic Isotope Geochemistry

Applications are invited for a technical position in $^{40}Ar-^{39}Ar$ geochronology. The position is for two years subject to renewal. Candidates should have a Masters degree in physics, chemistry or geology and experience in mass spectrometry and vacuum techniques.

Applicants for either post should send a resumé and names and addresses of at least three references by February 15, 1989, to **Dr. Alex Halliday, Department of Geological Sciences, University of Michigan, 1006 C.C. Little Building, Ann Arbor, MI 48109-1063.**

The University of Michigan is an Equal Opportunity/Affirmative Action Employer. (NW3063)A

RESEARCH ASSISTANT

SOMATIC CELL GENETICS

CAMBRIDGE UNIVERSITY,
UK/ELEANOR ROOSEVELT INSTITUTE, DENVER, USA

Research Assistant required for joint project between a Cancer Research Campaign funded group in the UK and the Eleanor Roosevelt Institute, Denver, USA. The purpose is to develop somatic cell hybrid resources for mapping the gene for multiple endocrine neoplasia on human chromosome 10. The successful applicant will be seconded 6-12 months to the laboratory of Dr. Carol Jones in Denver before returning to the UK to the CRC-funded group which is expected to move to new laboratories in Cambridge in Spring 1989. Substantial previous experience in tissue culture is essential. The post is CRC funded; salary and conditions on Cambridge University scales £7,515-£12,760 for Research Assistant or £11,680-£14,500 for Research Associate. Duration of post not less than 3 years according to age and experience of applicant. Starting date early 1989 negotiable. Informal enquiries to Dr. Bruce Ponder (01-643 8901 ext 4693) or Section of Human Cancer Genetics, Institute of Cancer Research, Sutton, Surrey SM2 5NG.

Applications in duplicate to the **Personnel Officer, Institute of Cancer Research, 17a Onslow Gardens, London SW7 3AL** quoting ref. no. 12.88.T.NS.59. (7983)A

TRUDEAU INSTITUTE, INC.

POSTDOCTORAL ASSOCIATE TO STUDY T CELL-MEDIATED IMMUNITY

A vacancy exists for a postdoctoral fellow interested in studying immunity to tumor and histocompatibility antigens. Current studies deal with various aspects of T cell-mediated rejection of tumors and allografts. The opportunity to study T cell-mediated immunity to bacterial infection also exists. Applicants should have basic training in immunobiology. Starting salary will be commensurate with experience and includes liberal fringe benefits. Subsidized institute housing is available.

The Trudeau Institute is a private, not-for-profit, basic medical research institution located on the shore of Saranac Lake and near Lake Placid, N.Y.

Send curriculum vitae and names of three references to:
Dr. Robert J. North, Director Trudeau Institute, Inc., P.O. Box 59, Saranac Lake, NY 12983. (NW3080)A

MOLECULAR GENETICIST

(Gene Mapping)

DIVISION OF TROPICAL ANIMAL PRODUCTION

TROPICAL CATTLE RESEARCH CENTRE
ROCKHAMPTON, QUEENSLAND
AUSTRALIA

A$31003 - A$38045

PROJECT: The project will establish a primary bovine genetic map in order to develop gene probes for cattle. The two phases involve firstly the establishment of DNA banks from selected reference families. Secondly RFLP linkage mapping will be carried out within the reference families. It is envisaged that the isolation of bovine specific hypervariable sequences will be required. Additional linkage studies using reference families will be conducted by collaborating groups throughout the world.

DUTIES: Specific duties will include selection and isolation of genes/markers to be mapped, RFLP studies within the reference families and liaison with collaborating groups. Interaction with other molecular genetics projects is envisaged.

QUALIFICATIONS: Applicants should have a Ph.D or equivalent qualification in molecular biology/genetics or related fields. Experience in RFLP linkage mapping, cloning and comparative gene mapping is desirable.

CONDITIONS: The initial appointment will be for a period of three years with Australian Government Superannuation benefits available. Assistance with relocation will be offered.

APPLICATIONS: Stating relevant personal particulars including details of qualifications and experience, the names of at least two professional referees and quoting reference number (RDT02) should be directed to:

The Chief,
CSIRO Division of Tropical Animal Production,
Box 5545,
Rockhampton Mail Centre,
Queensland 4702
AUSTRALIA
Fax: 6 17 079 36 1288

MOLECULAR GENETICS
Three positions

We are looking for three individuals to staff a new molecular genetics and *in situ* hybridization unit at the Whitney Laboratory. One position will be at the senior postdoctoral level and will be filled by someone with broad experience in various aspects of molecular genetics. This individual will be responsible for overseeing the unit and providing technical advice to other investigators in the Laboratory. The two other positions are at the junior postdoctoral level. One will have experience in the techniques of molecular genetics and a desire to learn electrophysiology; the other will have experience in electrophysiology (preferably intracellular recording and whole-cell and single-channel voltage clamp) and a desire to learn molecular genetics.

The Whitney Laboratory is the Institute for Marine Biomedical Research and Biotechnology of the University of Florida, and an Equal Opportunity Employer. Contact: **Dr. Peter A.V. Anderson, The Whitney Laboratory, 9505 Ocean Shore Blvd., St. Augustine, FL 32086.** (NW3047)A

The Polytechnic operates a range of degree and post graduate level courses, has a vigorous and successful record of consultancy and research and with the advent of Corporate Status the Polytechnic is entering a new and challenging phase of its development. To maintain and extend the programme of work, applicants are invited for the following post:

SCHOOL OF PHARMACEUTICAL & CHEMICAL SCIENCES

Head of School

Salary – HOD VI – £24,084 - £26,538

Applicants for the post should possess high academic credibility and also have the ability to manage the School as a budget centre, be able to lead in academic development and entrepreneurial initiatives. The person appointed would be eligible for consideration for appointment to the Professoriate.

The School of Pharmaceutical and Chemical Sciences is one of 3 Schools in the Faculty of Science and has an establishment of 30 academic staff. The School embraces the disciplines of chemistry and pharmacy (except for pharmacology).

Informal contact: Professor J. R. Brown, Dean of Faculty (091) 5152504.

Application forms and further particulars can be obtained from the Personnel Officer, Sunderland Polytechnic, Langham Tower, Ryhope Road, Sunderland, SR2 7EE or telephone (091) 5152429.

Closing date: 13.2.89. (8018)A

SUNDERLAND POLYTECHNIC

MICROBIAL ECOLOGY ASSISTANT PROFESSOR HARVARD UNIVERSITY

The Department of Organismic and Evolutionary Biology, Harvard University, invites applications for a faculty position in the field of microbial ecology, with special emphasis on symbiotic interactions between microorganisms and higher organisms. Candidates should have demonstrated excellence in research and a strong commitment to teaching at the undergraduate and graduate levels, including participation in courses in microbial diversity and ecology. Applications including a curriculum vitae, statement of research interests, reprints, and three letters of reference should be sent by March 1, 1989, to:

Dr. Andrew H. Knoll
Chairman Search Committee in Microbial Ecology
Department of Organismic and Evolutionary Biology
Harvard University
26 Oxford Street
Cambridge, Ma. 02138

Harvard University is an Affirmative Action/Equal Opportunity Employer. (NW3082)A

Friedrich Miescher-Institut Basel, Switzerland.

POSTDOCTORAL FELLOW

A postdoctoral position is open for a biochemist to join the group of Dr. Josef Jiricny. The project entails the isolation and characterization of human DNA repair proteins. The successful candidate should be familiar with the techniques of protein purification. Previous postdoctoral experience is desirable but not essential.

The Institute offers excellent research facilities. The appointment would be initially for one year, with extension foreseen for a further two years. Applications enclosing a curriculum vitae and a list of publications, as well as the names and addresses of two academic referees, should be sent to:

Dr. Josef Jiricny,
Friedrich Miescher-Institut,
PO Box 2543, CH-4002 Basel,
Switzerland.
(Tel: 061-6976661
or 6975046).

PUBLIC HEALTH LABORATORY SERVICE BOARD

PHLS CENTRE FOR APPLIED MICROBIOLOGY & RESEARCH
DIVISION OF BIOTECHNOLOGY

MICROBIOLOGIST

A graduate technician is required to join the Thermophile Research Section. The successful applicant will be involved in genetic and physiological studies of a wide range of thermophilic microorganisms.

This appointment will be at Basic Grade Microbiologist or Medical Physics Technician grade IV, depending upon qualifications and experience.

Salary range: £6,763-£10,496 (pay award pending).

NHS terms and conditions.

Candidates wishing to informally discuss the post should contact Dr R. J. Sharp, tel: Idmiston (0980) 610391, ext. 443.

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wilts SP4 0JG. Tel: (0980) 610391, to whom completed forms should be returned by 23rd January 1989 quoting Post No. 0809. (7997)A

THE UNIVERSITY OF SYDNEY

Australia

Applications and expressions of interest are invited for the following Chairs in the Faculty of Veterinary Science which will become vacant in January 1990.

CHAIR OF VETERINARY PATHOLOGY

Reference no. 48/19

The Department is responsible for teaching, research and diagnostic services in the field of Clinical Pathology, Microbiology and Parasitology. Veterinary qualifications or experience in teaching pathology to Veterinary Science students would be desirable.

CHAIR OF VETERINARY PHYSIOLOGY

Reference no. 48/03

Veterinary qualifications or experience in teaching physiology to Veterinary Science students would be desirable.

Intending applicants should obtain detailed statements of information concerning the Chairs from the Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

Salary will be at the rate of A$63,397 per annum.

The University reserves the right not to proceed with any appointment for financial or other reasons.

Applications, in duplicate, quoting reference no., including curriculum vitae, list of publications and the names, addresses and FAX numbers of three referees, to the Registrar, Staff Office, University of Sydney, NSW 2006, Australia (FAX +612 692 4316).

Applications close: 8 March 1989.

Equal employment opportunity is University policy. (W5712)A

POSTDOCTORAL FELLOW — MOLECULAR BIOLOGY OF LUNG DEVELOPMENT. Position available 1 July 1989 in NIH-supported laboratory program to study mechanisms of hormone effects on gene expression during development of lung cells. Qualifications: Ph.D. with background in molecular biology. Please contact: **Dr. Donald L. Shapiro, Department of Pediatrics (Box 651), University of Rochester School of Medicine, 601 Elmwood Avenue, Rochester, NY 14642. Telephone: 716 275-5884.** *An Equal Opportunity Employer M/F.* (NW3073)A

ACADEMIC PHYSIOLOGIST

The Department of Anesthesiology of Loyola University Stritch School of Medicine, Maywood, Illinois is recruiting a physiologist for a faculty position at the Assistant Professor level to work in a stimulating environment that includes excellent research laboratory. The candidates for this position are expected to have a strong commitment to innovative research in cardiovascular and respiratory physiology and ability to run large animal experiments in collaboration with the departments physician faculty and resident trainees. The salary is competitive and Loyola University is an Equal Opportunity Employer.

Please submit curriculum vitae, reprints, a statement of research interests, and arrange to have three letters of recommendations sent directly to:

Tadikonda L.K. Rao, M.D
Department of Anesthesiology
Loyola University
2160 S. First Avenue
Maywood, Illinois 60153 (NW2895)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)
DEPARTMENT OF CLINICAL PHARMACOLOGY

SENIOR RESEARCH OFFICER (postdoctoral): pharmacology/physiology

Applications are invited from postdoctoral scientists for an MRC funded position in an interdisciplinary research group studying the role of cell infiltration and mediator release in the lungs in asthma. The post provides excellent opportunities for working at all stages of the pharmacology and physiology of asthma, from basic biochemical mechanisms through animal studies to man. Applicants should have a Ph.D. in pharmacology, physiology or a related discipline.

The post is funded on an MRC programme grant until May 1991.

Salary on Range 1A.

Application forms and further particulars are available from the **Personnel Officer, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0NN (tel: 01-740 3204)** quoting ref: **AEB2.**

Closing Date: 19.1.89. (7978)A

Emory University
Woodruff Chair in Molecular Genetics

Emory University announces the creation of an endowed chair; the Woodruff Professorship in Molecular Genetics. An interdepartmental program in Genetics exists in the Division of Biological Sciences and currently consists of over 25 faculty. Research interests represent most areas of modern molecular genetics encompassing a wide variety of systems ranging from the human to viral organisms and there is considerable collaborative interaction among the genetics faculty. The chair will be an independent unit reporting directly to the Dean of the School of Medicine and will include additional new faculty positions and an initial 5,000 square feet of newly constructed laboratory space as well as competitive seed funds and salary. Investigators with active research programs capable of providing campus-wide leadership in research and training in this discipline, including established investigators as well as those with unusual promise and a developing international reputation, are encouraged to apply.

Submit applications or nominations by February 15, 1989 to: **Woodruff Molecular Genetics Search Committee, Emory University School of Medicine, 1440 Clifton Road, NE, Atlanta, GA 30322.**

An Affirmative Action/Equal Opportunity Employer (NW3077)A

UNIVERSITY of GUELPH

CHAIR — DEPARTMENT OF ZOOLOGY
COLLEGE OF BIOLOGICAL SCIENCE

Nominations and applications are invited for the Chair of Zoology in the College of Biological Science. The candidate should be an outstanding scholar with a strong commitment to excellence in graduate and undergraduate education. The Department of Zoology has 30 faculty members with diverse research interests, particularly in ecological and physiological aspects of fisheries, marine, and wildlife biology. Approximately 60 graduate students are enrolled for the MSc/PhD degrees and 300 students are specializing in the four departmental undergraduate programs.

The College of Biological Science is currently reorganizing its curriculum. It requires an academic with strong leadership skills as the Chair of the Department of Zoology to meld the considerable strengths within the department, to recruit new faculty, and to provide direction for the 1990's.

Candidates should submit a curriculum vitae, a list of publications, and the names of at least 3 referees to:

Dr. Bruce H. Sells
Dean
College of Biological Science
University of Guelph
Guelph, Ontario
Canada N1G 2W1

Deadline for receipt of applications is February 28, 1989. Subject to final budgetary approval.

In accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents.

The University is committed to Employment Equity.

(NW3021)A

UNIVERSITY OF SURREY
DEPARTMENT OF BIOCHEMISTRY

Postdoctoral Research Fellow (Project Leader) Nursing Practice Unit

Applications are invited for the post of Project Leader in the above Unit.

The NPRU is engaged on a number of fundamental research projects involving a range of biological and social sciences. The successful applicant will join an established programme of research studying aspects of hospital acquired infection. The person appointed will be responsible for the completion of the current project investigating the aetiology, incidence and prevention of catheter associated bacteriuria and for initiation of further research related to the use of invasive medical devices.

Applicants from a wide range of academic disciplines will be considered but possession of a PhD is essential. The post will be available for 18 months in the first instance. Salary will be up to £13870 per annum on the Research and Analogous Scale 1A, according to age, qualifications and experience.

Applications in the form of a curriculum vitae (3 copies) including names and address of two referees should be sent to the **Personnel Office (JLG), University of Surrey, Guildford GU2 5XH,** quoting reference 750aN by 20 January 1989. Further details may be obtained from Professor R Crow or Dr A Mulhall, 0483 571281 Ext 2549 or 2566. (8016)A

AFRC INSTITUTE OF FOOD RESEARCH, READING LABORATORY, SHINFIELD READING

Opportunities in protein structure, design and engineering

Two positions are available within our active protein engineering group. One at postdoctoral level, is funded by the E.C. and is in collaboration with the University of Groningen. The other, funded by the AFRC, affords the opportunity to study for a PhD. and is in collaboration with Birkbeck College, London.

(1) Postdoctoral position for the rational modification of the specificity of phospholipase A2

Phospholipase A2 is an excellent model system for investigating protein-phospholipid interactions. Inhibitors of phospholipase are pharmaceutically important and modified enzymes have great industrial potential. We are now initiating molecular simulation and free energy calculations to complement our existing protein engineering effort. This project is part of a three-way collaboration involving the Universities of Utrecht and Groningen and Reading Laboratory.
The appointment is for two years in the first instance, available now, and is funded by the E.C. Biotechnology Action Programme.
Qualifications required: PhD. in molecular simulation, protein structure, biomolecular computing or related area.
Salary on scale: £12,445–£17,032
Please quote reference R35/88

(2) Postgraduate position in protein structure and design

The aim of this project is to develop methods for adequately accounting for the solvation of charged and polar groups by solvent and protein. Such considerations are vital for accurate protein design. There will be ample opportunity to explore other aspects of protein structure including the design of mutants and X-ray analysis of cyrstallized mutant protein. The successful candidate will be able to register for a PhD. at Birbeck College, London.
This three year appointment is funded by the AFRC and available now.
Qualifications required: First or Upper second class honours degree in chemistry, physics, biological sciences or computation.
Salary on scale: £10,026–£13,460
Please quote reference R18/88

Excellent computer graphics facilities are available in Reading Laboratory and there is good access to ample computational power.

Closing date: 20th January 1989

The AFRC is an equal opportunities employer. (8020)A

PHARMACOLOGY — MOLECULAR BIOLOGY

Applications are invited for a tenure-track faculty position in the Department of Pharmacology of the University of Alabama at Birmingham (UAB). Comprising the Medical Center, University College and the Graduate School, UAB is a dynamic institution which is ranked as one of the top twenty comprehensive health and research centers in the U.S. The Pharmacology Department has a young well-funded faculty, is well-equipped and offers an excellent environment for research including competitive salaries, space and start-up funds. Applicants should have a relevant Ph.D. or M.D. degree, postdoctoral or faculty experience and be committed to a productive, independent research program and excellence in teaching. Rank is open but Assistant Professor is the likely level of appointment. We are seeking outstanding individuals whose interests and background are in the application of modern techniques of molecular and cellular biology and biochemistry to important problems in pharmacology. Send curriculum vitae, a brief statement of research interests and three letters of reference to: **Dr. Elias Meezan, Chairman, Department of Pharmacology, University of Alabama at Birmingham, Birmingham, AL 35294.** *UAB is an Equal Opportunity/Affirmative Action Employer.* (NW3084)A

THE UNIVERSITY OF NEW SOUTH WALES
Sydney, Australia

PROFESSOR OF CLINICAL PHARMACOLOGY AND DIRECTOR, DEPARTMENT OF CLINICAL PHARMACOLOGY AND TOXICOLOGY AT ST. VINCENT'S HOSPITAL

Applications are invited for appointment to the above position. Applicants should possess medical qualifications registerable in New South Wales and have appropriate teaching, research and clinical experience.

The Chair is in the School of Physiology and Pharmacology. The successful applicant will have similar standing in the School of Medicine. The Directorship of the Department of Clinical Pharmacology and Toxicology at St. Vincent's also involves responsibility for the New South Wales State Reference Laboratory for drug analysis and clinical responsibilities within that teaching hospital and for consultations in toxicology referred from other hospitals.

The Professor will participate in the undergraduate teaching programs in pharmacology clinical pharmacology, toxicology, and therapeutics on campus and at St. Vincent's Hospital and will also be involved in the development of these programs in the new Six Year medical curriculum. Responsibility for the coordination of teaching programs in these disciplines at the other teaching hospitals of the University of New South Wales is also involved. The appointee will be expected to engage in and promote research and advanced studies in the field of the Chair. Further information may be obtained from Professor W. E. Glover, Dean, Faculty of Medicine, or from Professor Ian McCloskey, Head, School of Physiology and Pharmacology.

The salary will be A$63,397 per annum and a clinical loading of A$11,176 per annum is also payable. There is an additional 'on call' allowance of A$13,003 per annum payable by the Hospital. There is also a 'clinical duties (Public Hospitals)' allowance payable by the Hospital of between A$9,390 and A$17,736 per annum depending on the level of administrative and service responsibility in the Hospital. Limited rights of private practice are also available. The University reserves the right to fill any Chair by invitation.

Details of the position, together with the conditions of appointment and application procedure are available from the Senior Appointments Unit, The University of New South Wales, P.O. Box 1, Kensington, N.S.W. 2033 Australia.

Applications close: 6 February 1989.

Equality of employment opportunity is University policy.

(W5702)A

UNIVERSITY OF HONG KONG
Department of Physiology

POSTDOCTORAL FELLOW IN PATCH-CLAMP STUDIES

Applications are invited, preferably from those with experience of patch-clamp technique, for a WHO-supported project on the role of ion channels in fluid secretion in the epididymis.

Appointment will commence in Spring 1989 and is for one year in the first instance with possible extension for a further two years. Annual salary is about US$20,000+, with medical benefits provided. A return airfare will also be provided if required. At current rates, income tax will not exceed 15.5 per cent of gross income.

Send curriculum vitae, statement of research interests, and the names of three referees to: Dr P Y D Wong, Department of Physiology, Faculty of Medicine, University of Hong Kong, Sassoon Road, Hong Kong. Tel: (852) 5-8199202, Telex: 71919 CEREB HX, Fax: (852) 5-479907. Closing date: January 31, 1989. (W5701)A

THE UNIVERSITY OF LEEDS
DEPARTMENT OF PATHOLOGY

PREDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above post available from 1 March 1989 for a fixed period of 36 months for work on RAS Mutations in Colorectal Cancer, involving the use of molecular biological techniques and the Polymerase Chain Reaction.

A good honours degree in Biochemistry or a related subject and experience in molecular biology would be an advantage.

Salary on R/A IB scale (£8,675-£11,680) according to qualifications and relevant experience.

Informal enquiries may be made to Dr Philip Quirke or Mrs J Fearnley (tel (0532) 333399 or 333387).

Application forms and further particulars may be obtained from the **Registrar, The University, Leeds LS2 9JT**, quoting reference no. **102/36**. Closing date for applications **31 January 1989**. (8012)A

University of Nebraska Lincoln

FACULTY POSITION IN INFECTIOUS DISEASE RESEARCH

Twelve month tenure-track position. Should be interested in studying infectious disease pathogenesis, microbial virulence factors or host defense mechanisms. Training in bacteriology, immunology, molecular biology, pathology or virology is appropriate. Will be expected to develop a competitive research program and participate in training graduate students. Start-up funds, technical support, and excellent laboratory and animal isolation facilities (BL2 & BL3) are available. Requires PhD in an appropriate discipline, or a DVM with MS or PhD. Rank and salary will be commensurate with record of accomplishments.

Send curriculum vita, research interests/career goals, and three letters of reference by February 15 to: **Dr. John A. Schmitz, Head, Department of Veterinary Science, University of Nebraska-Lincoln, Lincoln, Nebraska 68588–0905. (402) 472–2952.**

Affirmative Action/Equal Opportunity Employer (NW3058)A

ASSISTANT PROFESSOR

Theoretical Ecologist or Theoretical Population Biologist. Applications are invited for a tenure track Assistant Professorship *beginning August, 1989.* Teaching responsibilities will include a theoretical ecology or population biology course and participation in undergraduate offerings. The University of Wisconsin-*Madison* is an Affirmative Action, Equal Opportunity Employer *and encourages women and minorities to apply.*

Please submit curriculum vitae, copies of publications, description of research and teaching interests, and have three letters of recommendation sent by 1 March 1989 to:

Chair, Population Biologist Search Committee
Department of Zoology
University of Wisconsin-Madison
Madison, Wisconsin 53706 USA
608-262-1087 (NW3065)A

University of York
Department of Biology

POSTDOCTORAL RESEARCH FELLOW

The above SERC-funded post is available immediately for a period of up to one year and nine months. The project involves molecular biological and biophysical characterization of the endomembrane ATPase H+ channel, particularly with respect to its evolutionary relationship to the F_0F_1 ATPase of energy-coupling membranes. The successful candidate will join an active group involved in research on various aspects of membrane transport.

Starting salary within the range £9,865 to £10,460 per annum, with USS.

Three copies of applications, with full curriculum vitae and naming two referees, should be sent by 27 January 1989 to Registrar's Department (Appointments), University of York, Heslington, York Y01 5DD. Please quote advertisement reference number 7/7148C.

Informal enquiries to Dr D. Sanders (tel. 0904-432825) or Dr P. Rea (tel. 05827-63133 ext. 2264). (7993)A

KING'S COLLEGE LONDON
BIOMEDICAL SCIENCES DIVISION

Lectureship in Pharmacology

Applications are invited for a post of Lecturer in Pharmacology in the Biomedical Sciences Division. Applicants should show clear evidence of research potential or, in the case of older applicants, of research achievement in a branch of Pharmacology.

Salary within Lecturer Scale Grade 'A' range £9,260 pa–£14,500 pa plus £1,650 London Allowance, or 'B' range £15,105 pa–£19,310 pa plus £1,650 London Allowance according to age, experience, etc.

Further particulars and application forms from **Mr G A Cuthbert, Personnel Department, King's College, Strand, London, WC2R 2LS.** Closing date 31st January, 1989. (8002)A

Physicist

Nuclear Structure Facility — Ref DL/84

Daresbury Laboratory operates a 20MV Tandem Van de Graaff Accelerator for heavy ion nuclear structure research. This international facility is used by research groups for the UK and abroad.

• The Job

A vacancy exists for a physicist in the NSF Injection Systems and Developments group. The group is responsible for the development and operation of a wide range of ion sources for the accelerator, including those for polarised and radioactive beams. Although primarily working on ion sources the appointee will also participate in the general development programme of the facility where a superconducting linear accelerator booster is being installed.

• The Person

The successful applicant will be a graduate with practical ability and capable of understanding and applying the various areas of physics involved. He/She will work in collaboration with more senior members of the group from whom direction will be given. Someone with experience of ion sources would be preferred. The successful candidate will show the ability to understand and learn new ideas quickly and would be expected to develop rapidly.

Technical information can be obtained from Dr K A Connell on 0925 603496.

Station Scientist

Synchrotron Radiation Research — Ref DL/85

There is a vacancy in the Synchrotron Radiation Research Division for a station scientist. The successful candidate would be attached to the X-ray Diffraction Project team at the SRS Daresbury.

• The Job

The successful applicant will be responsible for the design, development and operation of diffraction equipment on the X-ray beam lines of the SRS. In addition to assisting and collaborating with external users, the station scientist will co-ordinate the work of computer and technical support staff. Development projects include the optimization of station software, and the testing of specialised environmental stages such as furnaces, cryostats and pressure cells. The candidate will also be expected to take an active part in the planning of diffraction stations to be constructed on the new wiggler beam-line.

• The Person

Applicants should have a relevant degree or equivalent qualification. They should be familiar with X-ray diffraction techniques on powders or single crystals, and have a sound background in crystallography, plus a flair for the design of unconventional instrumentation.

Further information can be obtained from Dr P Pattison (Tel. 0925 603154) or Dr R J Cernik (Tel. 0925 603238).

• Pay

Appointments will be made at the Scientific Officer or Higher Scientific Officer grade depending on qualifications and experience. Salary is in the range £8574 to £13460 with further increments depending on performance.

The superannuation scheme is non-contributory.

For an application form please quote the relevant reference number and contact:
The Personnel Officer,
Daresbury Laboratory,
Warrington WA4 4AD.
Telephone (0925) 603467
(24 hour answering service)

CLOSING DATE: 20th January, 1989. (8023)A

Daresbury SCIENCE & ENGINEERING RESEARCH COUNCIL

University of Basel — Department of Zoology

Academic Position in Cell Biology

This is a non-renewable academic position available for up to 5 years. We require a cell biologist to join a group investigating an in vitro transdifferentiation and regeneration system based entirely on striated muscle cells of jelly fish. The candidate should have a Ph.D and a good background in biochemistry. His/her work will focus on the mechanisms which stabilise cells in the differentiated state. It will include biochemical analysis of extracellular matrix components and application of mAb and standard cell biological techniques to early transdifferentiating cells. Some teaching duties are included. The salary will be in the range Sfr. 50'000-70'000 per year and will depend on experience and qualifications. Habilitation will be possible. Starting date: 1.3.89 or by arrangement. Applications including a c.v. and the names of two referees should be sent to **Prof. Dr. V. Schmid, Zoologisches Institut, Rheinsprung 9, CH-4051 Basel, Switzerland** (W5716)A

REGULATORY SPECIALIST

GARST SEED COMPANY is a member of the Agricultural Products Group of Imperial Chemical Industries PLC (London), the world's fourth largest chemical manufacturer and a world leader in discovery, technology, and innovation. The dedication of a new Bioscience Laboratory in Slater, Iowa in October of this year marked the consolidation of Garst's traditional plant breeding program with the international bioscience capabilities of ICI.

The Regulatory Specialist will report to Garst's Executive Vice President and Director of Research, and lead ICI/Garst through the regulatory process -

- Obtaining government approval for all aspects of new seed products;
- Monitoring the development of relevant regulations in North America;
- Formulating an overall registration strategy.

Inherent tasks will include planning and assembling a suitable package, negotiating with Federal and State officials, dealing with the press and public, streamlining systems and procedures, and consulting with our Government Relations staff in Washington.

We are looking for demonstrated **competence** - in familiarity with the regulatory process at state and federal level and awareness of trends and developments; in being equally at home with scientists, production, and marketing people; in being an effective spokesperson in varied forums in the private and public sectors; in understanding the entrepreneurial flavor of our business; and in skillful negotiation and the legal process. Any combination of degrees and experience contributing thereto would be welcome.

Position is located in Slater, Iowa, and will entail extensive travel throughout US and Canada, and possibly Central and South America.

We offer a competitive salary commensurate with experience, comprehensive benefits, high professional standards and respect, and - most importantly - the career association with a world leader in meeting farmers needs for the coming decade. Our growth over the past decade has been nothing less than phenomenal, and we invite your candidacy. Principals only. Please submit resume in confidence to **Charles T. Brodigan, Associate Employment Manager, ICI Americas, Wilmington, DE 19897.**

PHLS CENTRE FOR APPLIED MICROBIOLOGY & RESEARCH

DIVISION OF PATHOLOGY

AIDS SECTION

POST-DOCTORAL POSITION FOR A PROTEIN BIOCHEMIST

A position is now available to study Human Immunodeficiency Virus proteins. The three year post is funded by the MRC AIDS Directed Programme and the salary range is £11,164-£14,591 per annum (under review) depending on age and qualifications. Previous experience with protein purification and immunochemistry is essential. Familiarity with virological and tissue culture techniques would be desirable but not essential.

National Health Service terms and conditions will apply.

Further details can be obtained from Dr G W Farrar.

Applications forms are available from the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wilts SP4 0JG. Telephone (0980) 610391, ext 240 to be returned by 20th January 1989 quoting Post No. 0322.

(8019)A

CONDENSED MATTER EXPERIMENTAL PHYSICISTS
COLUMBIA UNIVERSITY
DEPARTMENT OF PHYSICS

The Department of Physics of Columbia University is searching for outstanding condensed matter experimental physicists at the assistant professor level.

The successful candidates will be provided with startup funds to suit the requirements of their research programs. There is no restriction on the subfield that will be considered. Tenure positions will be available for some of the physicists in this program who develop truly outstanding research programs and who also demonstrate excellent teaching skills. We will also consider applications, at this time, from more senior experimental condensed matter physicists who presently have the qualifications for a tenure position.

Finally we will consider applications from small, established, highly successful groups of experimental physicists who might be interested in moving as a group to Columbia. These positions will remain open until they are filled. Persons or groups interested in being considered for these postions should send their curriculum vitae, publication list, and a statement of their research interests to:

Professor S. Nagamiya
Condensed Matter Search Committee Chairman
Department of Physics
Columbia University
Box 3 Pupin
New York, N.Y. 10027

They should also arrange to have, at least three letters of recommendation sent to the same address. Columbia University is an equal opportunity/affirmative action employer. Women and members of minority groups are encouraged to apply for these positions.

(NW2914)A

THE UNIVERSITY OF TENNESSEE
MEDICAL CENTER AT KNOXVILLE (UTMC/K)

2 FACULTY POSITIONS
(tenure-track)

Two (2) tenure-track faculty positions — **MEDICAL ONCOLOGIST/ CLINICAL INVESTIGATOR** and **MOLECULAR IMMUNOLOGIST/ PROTEIN BIOCHEMIST** — at the assistant/associate professor level for MD/PhD candidates available in the Department of Medicine's Human Immunology and Cancer Program. NIH- and ACS-supported clinical and basic science research with emphases on human light chain-associated renal and systemic diseases (multiple myeloma, amyloidosis, etc.) and B cell-related neoplasms (lymphoma, leukemia, etc.). The successful candidate will work in well-equipped, state-of-the-art basic and clinical research facilities including hybridoma/Mab, flow cytometry, protein sequence, and immunochemistry laboratories. These positions are immediately available and require a minimum of 3 to 5 years of postdoctoral experience and ability to conduct innovative research. For MD candidates, BC/BE and eligibility for state licensure required. Excellent compensation (including fringe benefits) and academic rank commensurate with education and experience. The Knoxville area offers the scientific resources of the Univ. of Tennessee and the Oak Ridge National Laboratory, recreational opportunities provided by the surrounding Great Smoky and Cumberland Mountains and extensive TVA lake system; and cultural amenities including a symphony and chamber orchestra, a major fine arts museum, opera, and theatre. Letter of application, CV, and names and addresses of 3 reference sources should be sent to: **Alan Solomon, M.D., Professor o Medicine, and Head, Human Immunology and Cancer Program University of Tennessee Medical Center/Knoxville, 1924 Alco Highway, Knoxville, Tennessee 37920.** *The University of Ter nessee is an affirmative action, Title IX/Section 504 employer.*

NEUROSCIENCES FACULTY POSITION UCR/UCLA PROGRAM IN BIOMEDICAL SCIENCES

The UCR/UCLA Program in Biomedical Sciences, which offers an accelerated M.D. curriculum jointly between the University of California, Riverside (UCR), and the University of California, Los Angeles (UCLA), School of Medicine, has a tenure-track faculty opening in the Division of Biomedical Sciences at UCR available July 1, 1989. The prospective level of appointment for candidates who must possess the Ph.D. or M.D. degree may be at the Assistant, Associate or Full Professor. Primary teaching responsibilities will be in a 10-week course in neurosciences taught to 24 first-year medical students. Prior medical school teaching experience is strongly preferred. Also the successful candidate should actively participate in graduate student training. Junior applicants should have postdoctoral research experience, should be able to develop a strong independent research program and must possess a strong commitment to teaching. Senior applicants should have a clearly demonstrable record of research productivity, success in obtaining extramural funding and demonstrated teaching effectiveness. We would particularly welcome applications from individuals with research expertise in cellular or molecular neurobiology. The University of California is an Affirmative Action/Equal Opportunity Employer. The deadline for applications and nominations is February 28, 1989. Applicants should send a curriculum vitae, bibliography, two to three representative reprints, a statement of present and future research goals, and the names of three references.

CELL IMAGING SCIENTISTS

Postdoctoral positions available for imaging research on new laboratory systems at the Mayo Foundations (S. R. Taylor) and UCLA School of Medicine (K. P. Roos). Applicants should have a career interest in bioengineering and research interests that complement those of existing members of a group studying contraction and excitation-contraction coupling in isolated living muscle cells. The Mayo site is the administrative base, and has a primary interest in acquisition and analysis of data from skeletal muscle (S. R. Taylor). The Los Angeles site has the same analytical tools and a primary interest in cardiac muscle (K. P. Roos). Possible areas of interest for an applicant include: (i) development of mathematical methods for image processing and analysis. (ii) artificial intelligence, (iii) pattern recognition, and (iv) hardware design for high-speed CCD acquisition of bright field or low-light level intensified images. Skill in communication with scientists from different disciplines as well as the ability to work independently major factors. Send application letter, résumé, and addresses and telephone numbers of three references to: **S. R. Taylor, PhD., Mayo Foundation, 711D Guggenheim Building, Rochester, MN 55905.**

COLLAGEN BIOCHEMIST/ENZYMOLOGIST

RESEARCH FELLOW

A$31003 pa — A$38045 pa

Division of Fisheries Tasmania, Australia

The Program: The Seafood Technology Section of the Division of Fisheries carries out a program of work in research, development and liaison concerning the properties, processes and storage characteristics of Australian seafoods.
The appointee will undertake research into the mechanisms of post mortem change in collagen and in softening of fish flesh, isolate and characterize enzymes responsible for the collagenolytic activity, locate these enzymes in the intact tissue and explore potential uses for them in seafood and food processing.
Applicants should hold a PhD or equivalent qualification in one of the following; biochemistry, enzymology, pathology or immunology. Post-graduate research experience in one of the above with a knowledge of collagen biochemistry, its metabolism and degradation by enzymes is essential. Experience in extraction, isolation and purification of collagen fractions and collagenases or lysosomal enzymes is necessary together with a demonstrated ability to plan and implement goal-oriented research. A knowledge of muscle structure and function, post mortem biochemistry and experience with electrophoretic techniques and electron microscopy is advantageous.

Conditions: Appointment will be for a 3 year term to 31/12/91 and Australian Government Superannuation benefits are available. The appointee will be located at the CSIRO Tasmanian Regional Laboratory, in Hobart in the first instance but may be required to transfer to the Division's Laboratory, in Cleveland near Brisbane in the future.

More Information: Further information and a copy of the job description and selection criteria can be obtained from Mr. A. Bremner on Aust. (002) 201444 or Fax Number (002) 201419 or (002) 240530.

Applications should be submitted by the 27th of January 1989 and quote reference number FC 88/40. They should be framed against the selection criteria and should state relevant personal particulars including details of qualifications and experience. Applicants should nominate at least two professional referees and address their applications to:

In der **Fakultät für BIOLOGIE** ist zum 01. April 1991 eine

C4 — PROFESSUR

für **Allgemeine Botanik** (Nachfolge Prof. Dr. M. Bopp)

wiederzubesetzen.

Bewerber/innen sollten auf aktuellen Forschungsgebieten arbeiten. Es wird erwartet, daß sich der/die zukünftige Stelleninhaber/-in am Lehrprogramm des Grund- und Hauptstudiums beteiligt.

Bewerbungen mit den üblichen Unterlagen sind bis zum **15.04. 1989** an den Dekan der Fakultät für Biologie, Universität Heidelberg, Im Neuenheimer Feld 234, 6900 Heidelberg, zu richten. (W5705)A

THE UNIVERSITY OF LEEDS
DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY
ST JAMES'S HOSPITAL

LECTURER (BIOCHEMISTRY)

Applications are invited for the above post available from 1 April 1989.

Salary is on the non-clinical academic scale for Lecturers (Grade B) (£15,105-£19,310) according to qualifications and relevant experience.

The applications of biochemistry in the speciality are extremely broad and the applicant will have opportunities for research in almost any aspect of biochemistry. The successful applicant will also have teaching opportunities, amounting to two or three sessions per week, in both the Biochemistry Department and the University Department of Obstetrics and Gynaecology. The Department has facilities for most biochemical techniques, including radio-immunoassay, HPLC and electrophoresis.

Informal inquiries about the post may be made to Professor R J Lilford, Department of Obstetrics and Gynaecology, St. James's Hospital, Leeds LS9 7TF, (tel. (0532) 433144 Ext. 5872/4524, evenings (0532) 663227, or (0860) 629 752).

Application forms and further particulars may be obtained from and completed applications forwarded to the **Registrar, the University, Leeds LS2 9TJ, (tel (0532) 333965 — direct line), quoting reference number 99/6.** Closing date for applications 26 January 1989. (7984)A

MRC AIDS DIRECTED PROGRAMME
University of Edinburgh

RESEARCH FELLOW

A postdoctoral scientist is required to join a group working on cellular and molecular aspects of Human Immunodeficiency Virus. The vacant position is available for 3 years from 1st January 1989 to study the antiviral effects of substituted oligonucleotides and is funded by an MRC project grant to Dr. T. Brown (Department of Chemistry) and Drs. J.O. Bishop and A. J. Leigh Brown (Department of Genetics).

The appointment will be on the Research Grade 1A scale with a starting salary up to a maximum of £13,870 for a suitably experienced candidate.

Candidates with a background in virology, cell or molecular biology are encouraged to apply, with full C.V. to:
The Departmental Superintendent, University of Edinburgh, Department of Genetics, West Mains Road, Edinburgh EH9 3JN

Further information may be obtained from Dr J.O. Bishop (031 667 1081 ext. 3553) or Dr A.J. Leigh Brown (031 667 1081 ext. 3551). *Please quote reference no. 5619* (7976)A

UNIVERSITY OF WARWICK

RESEARCH TECHNICIAN

Department of Biological Sciences

The Department of Biological Sciences has a vacancy in the Animal Molecular Genetics Group, to work with Dr Cahir O'Kane on embryonic neural development in *Drosophila*. Experience of, or interest in genetics or Molecular Biology would be an advantage.

Salary on Technician Grade 3 scale: £6,636-£7,828 pa.

Application forms from the **Personnel Office, University of Warwick, Coventry CV4 7AL (0203 523685) quoting Ref No 20/T/88/14** (please mark clearly on envelope). Closing date 19 January 1989.

AN EQUAL OPPORTUNITIES EMPLOYER (7982)A

UNITED MEDICAL AND DENTAL SCHOOLS
of Guy's & St Thomas's Hospitals

LABORATORY SCIENTIFIC OFFICER

Applications are invited for the post of Laboratory Scientific Officer in the Division of Medicine at our Guy's Campus (close London Bridge BR and London Transport) to work on a Medical Research Council-funded project on leukocyte/endothelial cell interactions. The successful applicant will be involved in tissue culture and the generation of monoclonal antibodies.

This post is tenable for one year in the first instance. Salary scale: £5,867 to £9,435 per annum (currently under review) plus £1,267 p.a. London Weighting Allowance, according to age, experience and qualifications.

For further information, please telephone Mr Parkes, Chief LSO, on 01-407 7600 x 3527. To apply, please write with full CV and names and addresses of two referees to:— **The Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH,** quoting Reference No. G/MED/264. Closing date: 31st January 1989. (7988)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)

RESEARCH ASSISTANT

DEPARTMENT OF PHYSIOLOGY

Applications are invited for the above post to work on the cellular actions of anaesthetics. The post is funded by the Wellcome Trust for three years. Candidates should hold a good honours degree in a relevant biological subject.

Salary will be on the Research Scale 1B plus £1,650 London Allowance and there will be the opportunity to register for a higher degree.

Further details can be obtained from Dr. G. Pocock or Dr. C. Richards 01-794 0500, extn. 4313/4315. Application by c.v. (with names and addresses of two referees) should be sent to the **School Office, Room G650, R.F.H.S.M., Rowland Hill Street, London NW3 2PF** by *20 January 1989,* from which full job descriptions are available (tel. 01-794 0500, extn. 4262). Please quote ref. *GP/CD.* (7980)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

RESEARCH ASSISTANT

Department of Medicine I
(Dermatology Laboratories)

Required for studies on skin microcirculation, lymph vessels and pathophysiology of oedema. The work involves imaging of human skin blood and lymph vessels by Fluorescence Video-microscopy and studies of interstitial fluid in lymphoedema and skin disease. The position is for 1-3 years and could lead to a PhD. It is under the joint supervision of Dr P S Mortimer (Senior Lecturer in Medicine/Consultant Dermatologist) and Dr J R Levick (Senior Lecturer in Physiology). Applicants should have a degree in Biological Science or Bio-engineering. Starting salary £8,675 in scale 1B for Research and Analogous Staff plus £1,450 London Allowance per annum. Further particulars and an application form from the **Personnel Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. Tel 01-672 9944 x 56019.** Closing date 26 January 1989. Quote reference 182/88. (7977)A

MEDICAL MOLECULAR BIOLOGY UNIT
DEPARTMENT OF BIOCHEMISTRY
UNIVERSITY AND MIDDLESEX SCHOOL OF MEDICINE

Applications are invited for the post of

Chief Technician

in the above Unit. This is a permanent post involving responsibility for the day to day running of a Unit containing thirty scientists applying molecular techniques to the study of human disease. Duties will include responsibility for ordering, organization of equipment maintenance and repair and supervision of other technical staff as well as some scientific research. Candidates should have previous technical experience in the biological sciences. Salary on the TG5 scale up to £9,549 (plus London Allowance £1,750) depending on age and experience. Applications to **Dr. D. S. Latchman, Medical Molecular Biology Unit, The Windeyer Building, Cleveland Street, London W1P. Telephone No. 01-636 8333 xt. 3100.** *Equal Opportunities Employer.* Closing date: three weeks after appearance of ad. (7990)A

Max-Planck-Institut für Molekulare Genetik
Otto-Warburg-Laboratory
for Biochemistry and Molecular Biology

POSTDOCTORAL POSITIONS

are available to work on

1) RNA processing in trypanosomes and HeLa cells, and the development of *in vitro* reconstitution and processing systems (Dr. Albrecht Bindereif),

or

2) structure and function of eucaryotic tissue-specific and developmentally regulated transcription factors (Dr. Claus Scheidereit).

Applicants should send curriculum vitae, summary of previous research experience, and names of two referees to

Dr. Albrecht Bindereif or **Dr. Claus Scheidereit**
Max-Planck-Institut für Molekulare Genetik
Ihnestr. 73
D-1000 Berlin 33
FRG (W5704)A

UNIVERSITY COLLEGE AND MIDDLESEX SCHOOL OF MEDICINE
DEPARTMENT OF MEDICINE
ACADEMIC UNIT OF DIABETES AND ENDOCRINOLOGY AT THE WHITTINGTON HOSPITAL

RESEARCH ASSISTANT

A research assistant post is available in this Unit based at the Whittington Hospital, Highgate, London N19. This exciting new Unit is working on areas covering the complications of diabetes, and the hormonal control of sodium balance. The successful applicant should have a science degree or equivalent and should be familiar with routine biochemical techniques, and have an enquiring approach and good organisational skills. Previous experience with radioimmunoassay and familiarity with techniques of platelet handling and methodology, and with computing would be an advantage. Salary Scale 1B £8,675 to £11,680 (+ LW £1,650) according to experience. For further information contact: Dr. John S. Yudkin MD FRCP or Dr. Peter J.A. Moult MD FRCP on 01-272 3070 ext 4189. Please submit applications and CV to:— **Dr. J S Yudkin or Dr. P J A Moult, Academic Unit of Diabetes and Endocrinology, Whittington Hospital, Archway Road, London N19 5NF.**

Closing date 26 January 1989.

Equal Opportunities Employer (8014)A

DEPARTMENT OF ZOOLOGY
UNIVERSITY OF HAWAII
PROFESSOR IN MOLECULAR BIOLOGY

We seek a senior faculty member with research interests in the biology of nucleic acids, proteins, carbohydrates or lipids. Applicants should: (i) have an active research program focussed on basic biological questions at the molecular level such as gene action and regulation, molecular evolution, or adaptive metabolism, and (ii) have an interest in enriching our undergraduate program in the area of molecular biology. The successful applicant will be selected on the basis of leadership potential to serve as Department Chair, outstanding research accomplishment demonstrating sustained program growth and development, and commitment to teaching excellence. We are particularly interested in individuals who enjoy interacting with biologists of diverse research interests, and whose research will thrive in the unique environment of the Hawaiian archipelago. The position is available as early as 1 August 1989.

Send curriculum vitae, summary of research and teaching experience and philosophy, reprints, and the names and addresses of three references to: **Dr. Robert A. Kinzie III, Chair, Search Committee, Department of Zoology, University of Hawaii, Honolulu, HI 96822.** Deadline for applications is 1 February 1989.

The University of Hawaii is an Equal Opportunity/Affirmative Action Employer. Women and minorities are encouraged to apply. (NW3056)A

THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE
(University of London)

MEDICAL MICROBIOLOGIST

We are looking for a Medical Microbiologist to join the Department of Clinical Sciences at the London School of Hygiene and Tropical Medicine, Keppel Street, London W1. The appointment will be made at the level of Clinical Lecturer/Senior Lecturer depending on experience.

The Department of Clinical Sciences was formed by the amalgamation of the department of Medical Microbiology, Clinical Tropical Medicine and Clinical Nutrition.

The post will involve full participation in the teaching commitments of the department, particularly the MSc in Medical Microbiology and the supervision of PhD students. Candidates will be expected to have an established research record and will participate in departmental research activities.

Salaries will be on the universities scale for clinical lecturers/senior lecturers — £13,470-£23,610 or £21,825-£30,800 plus £930 London Weighting. Please send completed application with curriculum vitae and the names of three referees to the **Personnel Officer, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT.** Closing date for applications 10 February 1989. (7979)A

PLANT MOLECULAR BIOLOGIST
McGill University

The Department of Biology invites applications for a tenure-track position in plant molecular biology. The successful candidate will be expected to develop a strong research program and to contribute to graduate and undergraduate teaching. The department has excellent facilities for plant growth and tissue culture.

The starting date will be on or before September 1, 1989. Rank and salary will be comensurate with experience.

Send curriculum vitae, statement of research interest, representative reprints, and have three letters of reference forwarded to:

Dr. Barid Mukherjee, Chairman, Department of Biology, McGill University, 1205 Avenue Docteur Penfield, Montreal, Quebec, Canada H3A 1B1. *Deadline for applications February 15, 1989.* (NW2994)A

POSTDOCTORAL POSITION

Position presently available for candidate with background in one or more of the following areas: pharmacology, biochemistry, cell biology, immunology or virology. Candidate will participate in research on the evaluation of anti-viral drugs in HIV *in vitro* and *in vivo* systems (nonhuman primates). Studies will be supervised by Dr. Jorg Eichberg. Appointments are for one year periods up to three years. Annual salaries range from $21,070 to $29,265 dependent upon previous postdoctoral experience. Send curriculum vitae with names and telephone numbers of three references to **Personnel Director (906), Southwest Foundation for Biomedical Research, P.O. Box 28147, San Antonio, TX 78284.** Equal opportunity employer m/f. (NW3060)A

RESEARCH ASSOCIATE IN BRYOLOGY
Farlow Herbarium
Harvard University

Applications are invited from systematists with Ph.D. in Botany who are conducting research in Bryology. Training and interests should include new or promising methodologies, techniques, or philosophies in systematic and evolutionary research. Primary responsibility will be to conduct an active research program in Bryology, as well as to participate in administration and curation activities of the Farlow Herbarium bryophyte collection.

Appointment to be annual with possibility of up to five years. Applications including a curriculum vitae, statement of research interests, reprints of recent publications and three letters of reference should be sent by March 1, 1989, to:

Dr. Donald H. Pfister
Harvard University Herbaria
22 Divinity Avenue
Cambridge, Ma. 02138

Harvard University is an Affirmative Action/Equal Opportunity Employer. (NW3081)A

ROYAL HOLLOWAY AND BEDFORD
NEW COLLEGE
University of London

LECTURESHIP IN GEOLOGY

Applications are invited for the post of Lecturer in Structural Geology/ Seismic Stratigraphy to work with a vigorous team researching into basin evolution. Field-based experience, mathematical skills and computer modelling abilities are fundamental requirements. Depending on qualifications and experience the appointment will be made on either Lecturer Grade A (£10,910-£16,150 inclusive) or Lecturer Grade B (£16,755-£20,960 inclusive).

Further details and application forms may be obtained from **Mrs F Maynard, Personnel Office, Royal Holloway and Bedford New College, Figham Hill, Egham, Surrey, TW20 0EX. Telephone Egham 34455 extension 3027.** Closing date for receipt of applications is 27th January 1989. (7995)A

Physical Oceanographer
Search Extended

Applications are invited for a tenure track, assistant or beginning associate professorship; Phd required.

We seek a process oriented oceanographer interested in using modern instrumentation in field studies of coastal and estuarine dynamics, an individual who can take advantage of diverse funding opportunities including state and local sources.

Expected is a strong commitment to teaching, advising graduate students, and developing a significant research program in an interdisciplinary setting, including the application of science to solving environmental and/or societal problems. Salary commensurate with experience.

Please send curriculum vitae, summary of research interests, and names of three referees by February 15, 1989 to **Dr. M.J. Bowman, Marine Sciences Research Center, SUNY Stony Brook, Stony Brook, NY 11794-5000.**

SUNY Stony Brook is an affirmative action/equal opportunity educator and employer. AK# 347. (NW3068)A

ASSISTANT PROFESSOR

Theoretical Ecologist or Theoretical Population Biologist

Applications are invited for a tenure track Assistant Professorship *beginning August, 1989.* Teaching responsibilities will include a theoretical ecology or population biology course and participation in undergraduate offerings. The University of Wisconsin-Madison is an Affirmative Action, Equal Opportunity Employer and encourages women and minorities to apply.

Please submit curriculum vitae, copies of publications, description of research and teaching interests, and have three letters of recommendation sent by 1 March 1989 to:

Chair, Population Biologist Search Committee
Department of Zoology
University of Wisconsin-Madison
Madison, Wisconsin 53706, USA
608-262-1087 (NW3085)A

University of Edinburgh
The Duke of Edinburgh Chair of Cardiology

The University Court invites applications for the Duke of Edinburgh Chair of Cardiology which is funded by the British Heart Foundation and becomes vacant on 1st July 1989, on the retirement of Professor Michael Oliver. The University seeks to appoint someone with wide experience of cardiology who has made significant contributions to knowledge of cardiovascular disease and who is capable of advancing understanding of the subject and of providing leadership for the staff of the Cardiovascular Research Unit. The appointee will also be expected to teach undergraduate and postgraduate students. He/she need not necessarily be medically qualified, but a clinician would be expected to contribute to the clinical service in the Royal Infirmary. Further particulars may be obtained from the **Secretary to the University, University of Edinburgh, Personnel Office, 63 South Bridge, Edinburgh EH1 1LS,** with whom applications (15 copies), including the names of three referees, should be lodged not later than 3rd March 1989. Overseas applicants need only supply one copy of application. *Please quote reference No. 60/88* (8007)A

HARVARD MEDICAL SCHOOL
MASSACHUSETTS GENERAL HOSPITAL

POSTDOCTORAL RESEARCH SCIENTIST
MOLECULAR AND DEVELOPMENTAL NEUROBIOLOGY

Postdoctoral scientist position available as of the spring of 1989 to study gene regulation during the development of neurons. Ongoing efforts include the identification of genes related to neuronal differentiation and plasticity, the study of their transcriptional control, and the analysis of their function by perturbation *in vitro* and in transgenic mice.

Interested persons should send curriculum vitae to:

Dr. Mark C. Fishman
Howard Hughes Medical Institute
Wellman 4
Massachusetts General Hospital
Boston, MA 02114 (NW3062)A

UNIVERSITY OF CAMBRIDGE
INSTITUTE OF ASTRONOMY

FACULTY POSITION

A post is available for an astronomer whose main duties would be research and the supervision of graduate students. The appointment is at the level of Senior Assistant in Research, and will be for an initial period of five years with the possibility of reappointment and upgrading. Although some preference may be given to candidates with theoretical interests, applications are welcome from astronomers whose research relates to any part of the Institute's programme.

The stipend is on the age-related scale £11,680 (age 27) to £14,500 (age 32 or above). Further information about the duties and conditions of the appointment may be obtained from the **Secretary of the Appointments Committee, Institute of Astronomy, Madingley Road, Cambridge CB3 0HA,** to whom candidates should send their applications (ten copies — overseas candidates need only send one copy) including a curriculum vitae and names of not more than three referees, so as to reach him not later than 17 February 1989. (8010)A

Childrens Hospital of Los Angeles

The Division of Research Immunology & Bone Marrow Transplantation of the Childrens Hospital of Los Angeles wishes to recruit individuals for a junior faculty position. The successful candidate will be expected to establish an independent research program with external funding and to engage in the clinical bone marrow transplantation program of the Division. Previous clinical experience in the areas of Hematology/ Oncology, Immunology and/or Infectious Disease is required. Research expertise in the area of oncology, molecular biology and/or immunology is preferred. Candidates should send their curriculum vitae, names of three references and a brief description of their research interests to:

Robertson Parkman, M.D.
Head, Division of Research Immunology
& Bone Marrow Transplantation
Childrens Hospital of Los Angeles
4650 Sunset Blvd.
Los Angeles, CA. 90027

The Childrens Hospital of Los Angeles and the University of Southern California, School of Medicine are Equal Opportunity Employers (NW3059)A

nature

the widest international selection of jobs in science — EVERY WEEK

Clinical Electrophysiologist

The Department of Otorhinolaryngology and Human Communication, University of Pennsylvania School of Medicine seeks a Ph.D clinical neurophysiologist. The applicant must have demonstrated expertise, at least five years experience and refereed publications in multimodality evoked potentials, with specialized expertise in intraoperative and intensive care monitoring of evoked potentials and quantitative EEG. Expertise in topographic brain electrical activity mapping is required. Contact: **Daniel M. Schwartz, Ph.D Division of BioelectroDiagnosis and Neural Monitoring, University of Pennsylvania Medical Center, 3400 Spruce Street, Philadelphia, Pa.**

The University of Pennsylvania is an Equal Opportunity Employer. (NW3069)A

DIRECTOR, RADIOIMMUNOASSAY CORE,

Diabetes Endocrinology Research Center, University of Washington Division of Endocrinology/Metabolism, Seattle, Washington. This is a research faculty position with rank dependent upon experience. The applicant should have a Ph.D. degree and a strong background in peptide chemistry and development of hormone radioimmunoassays. The major responsibility will be directing the Core laboratory which processes routine radioimmunoassays, and development of new assays as required by the Affiliate Investigators of the Center. Approximately 50% of time will be available for independent research, and independent grant support is highly desirable. Training, expertise, interest and capability in diabetes, endocrinology and metabolism research is desired. For further information please contact: **Dr. Leslie J. Klaff, Acting Director, Radioimmunoassay Core, Diabetes Endocrinology Research Center, Quarters 8, Pacific Medical Center, 1200-12th Avenue South, Seattle, WA 98144; Telephone: 206-543-6481.**

The University of Washington is an Equal Opportunity Employer. (NW3088)A

The Queen's University of Belfast

CHAIR OF EARTH RESOURCES

e University intends to develop present Department of Geo- y as a school of Earth Resour- , offering a strong geology core, directing its programmes ticularly to applied concerns ing from the mineral and rocarbon industries and explo- ion and economic utilisation of earth's resources. The Univer- wishes to appoint a Professor will initiate teaching grammes; develop research, ticularly in applied areas and end links with industry and loration companies. The per- appointed would initially become the Director of the School and have the opportunity to lead new developments in geology and earth resources in Northern Ireland. A significant expansion in staff is expected to accompany this appointment.

Salary will be within the professorial range with contributory pension rights under USS.

The appointment will be from 1 October 1989 or such other date as may be agreed.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: 27 February 1989 (Please quote Ref. 89/). The University is an Equal Opportunity employer. FEA Registration No. 575. (8026)A

POSTDOCTORAL POSITIONS BIOLOGICAL THEORY

Protein structure and function; DNA structure and function; neural net theory. Research potential more important than specific training.

For information, contact **Charles DeLisi, Chair, Department of Biomathematical Sciences, The Mount Sinai School of Medicine, Box 1023, One Gustave L. Levy Place, New York, NY 10029 6574.**

An Equal Opportunity Employer. (NW3051)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London)

MOLECULAR BIOLOGY

Applications are invited from suitably experienced pre-or post-doctoral scientists to join a group involved in studying the molecular genetics of atypical mycobacteria, particularly in relation to Crohin's disease in humans and Johne's disease of cattle. The work involves the use of DNA sequence from a newly, identified mycobacterial insertional element and PCR amplification, to assay disease and environmental samples for specific slow growing atypical mycobacteria.

The appointment is for 1 year initially with the possibility of extension, with a start my salary upto £13,130 inclusion of London Weighting. Applications together with the names and addresses of 2 referees to **Professor John Hermon-Taylor, Department of Surgery, St George's Hospital Medical School, Cranmer Terrace, Tooting, London SW17 0RE, tel 01-767 7631,** from whom further particulars may be obtained. Closing date 20 January 1989. Please quote reference 195/88. (7991)A

Cell Biologist
Biophysicist
Structural Biologist
Molecular Biologist

The Pennsylvania Muscle Institute and the University of Pennsylvania School of Medicine seek outstanding candidates for two tenure track positions in the area of fundamental cardiovascular or motility research. One position will be in the field of molecular genetics of contractile proteins.

The other position is in the broad area of cell biology, biophysics and/or structural biology of muscle. These positions are primarily aimed at, but not restricted to, the Assistant Professor level. Appointment will be made in the department appropriate to academic interest.

Applicants should send CV and research statements and the names of three references to: **Yale E. Goldman, M.D., Ph.D., Director of Pennsylvania Muscle Institute, School of Medicine, University of Pennsylvania, Philadelphia, PA 19104-6085.**

Equal Opportunity/Affirmative Action Employer. (NW3052)A

The Medical College of St. Bartholomew's Hospital

POST-DOCTORAL RESEARCH FELLOW

£11,517-£17,370 p.a.

A Research Fellow is required in the Department of Gastroenterology, St. Bartholomew's Hospital to work with a group of medical and basic scientists on the pathogenesis of some intestinal infections, particularly giardiasis and amoebiasis. The successful applicant would be involved in ongoing research, including the development of DNA probes for genetic analysis of parasites and for diagnosis. The group is also attempting to identify genes encoding for immunodominant parasite antigens. Previous experience in cell culture, monoclonal antibody production and molecular biological techniques is desirable.

Enquiries to Dr. M.J.G. Farthing to whom application should be made in the form of a curriculum vitae with the names of 3 referees to **St. Bartholomew's Hospital, West Smithfield, London EC1A 7BE. Tel: 01-601 8508/9/10.**

Closing date: 28th January. (8003)A

POSTDOCTORAL POSITION

Available in spring 1989 at 120,000 FF/year for research on molecular and/or cell biology of neuronal proteins and brain development. Send resume, publications and reference letters to **J. Nunez, Unité INSERM 282, Hopital Henri Mondor, 94010 Créteil France.** (W5698)A

Yale UNIVERSITY

The McKnight Foundation

Molecular Genetics of the Flowering Process

Graduate and Postdoctoral Fellowships

An interdisciplinary research program at Yale University sponsored by The McKnight Foundation.

Applications are invited for Graduate and Postdoctoral Fellowships to join an interdisciplinary research program undertaken by ten faculty members in three departments at Yale University (Biology, Molecular Biophysics & Biochemistry, and Forestry & Environmental Studies).

Ongoing projects include the following:

- genetic analysis of cell-cell interactions in floral structures
- mutational and molecular fine-structure analysis of floral genes
- ectopic expression of growth regulators in the flowering process

The training program also includes technical workshops, seminar programs, and extensive collaborative work. Graduate applicants must apply to the Director of Graduate Studies, Department of Biology, P.O. Box 6666, Yale University, New Haven, CT 06511 U.S.A., Telephone: (203) 432-3538 by March 1, 1989. Postdoctoral applicants should apply directly to the Project Coordinator with CV, three letters of reference, and a research interest statement. Postdoctoral fellows will be encouraged to develop independent collaborative projects on flowering.

For further information, contact Prof. Ian Sussex (Project Coordinator), Yale Biology Department, P.O. Box 6666, New Haven, CT 06511 U.S.A.

Yale University is an Affirmative Action/Equal Opportunity Employer.

(NW3070)E

RESEARCH FELLOWSHIPS IN NUTRITION FOR MEDICAL STUDENTS THE ROCKEFELLER UNIVERSITY

A program for one year research fellowships has been made available by the Pew Charitable Trusts. Medical students will be selected to join the Pew Center of Nutritional Excellence at Rockefeller University in New York City. The core activity of fellows will be investigative work in basic biomedical laboratories in Rockefeller University on projects relevant to human nutrition. Applicants should currently be in the junior year of any medical school in the U.S.A. A generous stipend and housing allowance will be offered to those selected for the fellowship year to begin July 1, 1989.

Applications must be completed no later than February 1, 1989 to allow for full consideration. A small number of applicants will be invited to New York City for interviews in March, 1989 and final selection will be made early in April. For application forms and further details write to:

Dr. Jules Hirsch
The Rockefeller University
1230 York Avenue
New York, New York 10021-6399

(NW3075)E

ROYAL SOCIETY OF EDINBURGH

BP RESEARCH FELLOWSHIPS

The next round of the prestigious post-doctoral BP Research Fellowships will be advertised shortly. The Fellowships are for research in: Mechanical Engineering; Solid State Sciences; Information Technology; Organic Chemistry (except natural product and biological chemistry); Geological Sciences. Applications are available from the **Executive Secretary, Royal Society of Edinburgh, 22-24 George Street, Edinburgh EH2 2PQ.**

The BP Research Fellowships were created in 1988 and launched at a reception, held at the Royal Society of Edinburgh in July attended by the Secretary of State for Scotland. Two BP Research Fellows were appointed and have taken up post; one at the University of Stirling and one at the University of Glasgow.

Dr Roger Watt came from Cambridge to the University of Stirling, where a new Centre for Cognitive and Computational Neuroscience is being set up. Dr Watt feels his BP Fellowship has helped a great deal in setting up this centre and explains its work.

"The centre will bring together mathematicians, computer scientists and psychologists with a common interest in the performance of new parallel computer architectures modelled on neural networks. We are principally concerned with studying vision, but by machine and people. Vision is a particularly useful task to study because it is something that humans are very good at, but which has proved immensely difficult even to begin to emulate in standard computer systems."

Dr Peter Haughton's BP Research Fellowship is to carry out research at the University of Glasgow on the 'Evolution of late-orogenic basins in the Betic-Rifian Orogeny of southern Spain and northern Morocco'.

The Royal Society of Edinburgh hopes to appoint two, or possibly three, BP Research Fellows to begin in October 1989.

(8005)E

The Unit 42 of the French National Institute of Health and Medical Research (INSERM U 42) is offering a

POST DOCTORAL RESEARCH FELLOWSHIP

for 1 year with the possibility of extension and further permanent position.

Applicants should possess a PhD or equivalent doctoral degree and have experience in

MOLECULAR BIOLOGY

with emphasis on CDNA/gDNA library, cloning and sequencing.

The major research project concerns the characterization of antigens of *Toxoplasma gondii* or *Pneumocystis carinii*. Experience in parsitology is not essential. Salary range is 8,00–14,000FF

Applications (with full C.V. and the names of 2 referees) and informal inquiries to:

Professor Daniel CAMUS
INSERM U 42
369, rue Jules Guesde
59650-Villeneuve d'Ascq
FRANCE

as soon as possible

EMBO
EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

SHORT TERM FELLOWSHIPS
in molecular biology

The European Molecular Biology Organization awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in exceptional circumstances. Inquiries should be accompanied by a self-addressed adhesive label.

Application forms and further details may be obtained from **Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R.G.** (W5706)E

UNIVERSITY OF LEICESTER
DEPARTMENT OF GENETICS
Postdoctoral Research Fellowship

Applications are invited immediately for an 18 month appointment funded by Action Research for the Crippled Child. (A further period of support will be sought for a suitable successful candidate). The project concerns the isolation of collagen cDNA clones for use in the investigation of inherited human connective tissue disorders. The successful candidate will join a group of six and will be experienced in some or all of the following areas: RNA isolation, construction and screening of cDNA libraries, RNase A protection mapping, cell culture, PCR amplification, Southern and Northern blotting, computing.

Applicants should possess a Ph.D. in a relevant subject. Salary, according to age and experience, on scale IA: £9,865 to £15,720. Informal enquiries may be made to Dr. Raymond Dalgleish on (0533) 523425. Applications, including a c.v. and the names of two referees should be sent to:– **Dr. R. Dalgleish, Department of Genetics, University of Leicester, University Road, Leicester LE1 7RH** as soon as possible.
(8017)E

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
MOLECULAR BIOLOGIST
Post-doctoral Fellowship/Pre-doctoral Research Assistantship

Available from January 1989 to work on a 2 year MRC funded project to find new ways to express AIDS virus antigen, in eukaryotic cells. Experience in molecular biology techniques would be an advantage. The successful candidate will join an active research team housed in a very well equipped suite of laboratories in the Department of Medical Microbiology.

Informal enquires can be made by telephoning Dr A Coates on 01-377 7259.

Applications including CV and the names of two referees should be sent to:

Miss J T Lewis
Assistant Secretary
The London Hospital Medical College
Turner Street
London E1 2AD

within 2 weeks of the date of this advertisement. (7986)E

POSTDOCTORAL FELLOW
ICRF
CLINICAL ONCOLOGY UNIT
INSTITUTE OF MOLECULAR MEDICINE
JOHN RADCLIFFE HOSPITAL, OXFORD

Applications are invited for a three year postdoctoral fellowship in the new ICRF Clinical Oncology Unit Oxford. The Honorary Director of the Unit is Professor Adrian Harris and the Senior Scientist in the laboratory is Dr. Ian Hickson. The laboratories are situated within the Institute of Molecular Medicine and the research interests of the Unit include cloning human DNA repair genes, drug resistance mechanisms and growth factors and their receptors.

Salary will be dependent on age and experience and in the range of £12,500 to £15,324.

Informal enquiries may be made to Professor Harris (0865 741841, Ext. 698) or Dr. Hickson (091 232 5131).

Applications should be made by sending a full CV and names and addresses of three referees to the Mrs P Harwood, Recruitment Officer, Imperial Cancer Research Fund, PO Box Lincoln's Inn Fields, London WC2A 3PX quoting ref 46/R by 31st January 1989.

Smoking is actively discouraged. (7994)E

IMPERIAL
CANCER RESEARCH FUND

STUDENTSHIPS

QUEEN MARY COLLEGE
(University of London)
Department of Chemistry
Postdoctoral Research Assistants and SERC CASE Studentships

Applications are invited for two postdoctoral positions. Both concern the synthesis and characterization of precursors suitable for producing thin films of electronics materials by Chemical Vapour Deposition. Experience in the handling of air-sensitive compounds is essential.

The first, under the direction of Professor D. C. Bradley, F.R.S., is concerned with metalo-organic precursors for III/V systems, and will involve research collaboration of an interdisciplinary nature with the electronics industry.

The second, under the direction of Professor B. J. Aylett, is concerned with volatile precursors for silicon-based systems and their deposition mechanisms, and will involve research collaboration with a leading company in the U.K. and California.

Two SERC-funded CASE awards are also available for suitably-qualified graduates. The work will be in similar areas to those detailed above.

Applications with a C.V. and names of two referees should be sent *before January 31st* to either of those named above at: **Department of Chemistry, Queen Mary College, Mile End Road, London E1 4NS.**

STUDENTSHIPS continued

DEPARTMENT OF PHARMACOLOGY
UNIVERSITY COLLEGE LONDON

Research Studentships

The Department will have a number of Research Studentships to offer, for work in the following areas:

1) Synaptic, ion channel and smooth muscle pharmacology
2) Central neuropharmacology (pain pathways, epilepsy, Parkinsonism)

and 3) Immunopharmacology (mediators of inflammation).

Applicants should hold, or expect to obtain, a good honours degree in Pharmacology or a related subject, and should write in the first instance to the **Departmental Postgraduate Tutor, Professor D.H. Jenkinson, Department of Pharmacology, University College London, Gower Street, London, WC1E 6BT.** Please enclose a full C.V. giving an indication of your interests, and the names of two academic referees. (8013)F

GRANTS & SCHOLARSHIPS

UNIVERSITY OF LONDON

EDMUND DAVIS SCHOLARSHIP IN MEDICINE, LAW OR ENGINEERING

Applications are invited from suitably qualified graduates of any university for the award of an Edmund Davis Scholarship tenable from October 1989. Under the terms of the benefaction preference will be given to applicants born in the geographical areas formerly known as Northern and Southern Rhodesia.

The Scholarship is awarded for full-time graduate work at a School of the University for an approved course leading to a Higher Degree at the University. The award is tenable for a period not exceeding three years.

Detailed information and application forms may be obtained from the Secretary, Scholarships Committee, University of London, Room 21A, Senate House, Malet Street, London WC1E 7HU, with whom completed applications and references must be lodged by **no later than 1 March 1989.** (7989)H

WORKSHOPS

MICROELECTRODE TECHNIQUES FOR CELL PHYSIOLOGY

The sixth workshop will take place at the Laboratory of the Marine Biological Association, Citadel Hill, Plymouth, UK from September 6th to 20th, 1989. The workshop aims to provide first hand experience in a number of electrophysiological techniques for postgraduate students and postdoctoral workers. The following techniques will be available:

1. **Patch-clamp**
2. **Voltage-clamp**
3. **Ion-sensitive microelectrodes**
4. **Intracellular dye injection**
5. **Fluorescent dye techniques**

The course fee of £950 includes accommodation, meals and tuition. Some bursaries will be available.

For application forms contact: **Dr. D. Ogden, Pharmacology, Kings College London, The Strand, London WC2R 2LS, UK.**

Closing date for applications: 31st March, 1989.

Microelectrode Techniques: The Plymouth Workshop Handbook is available from the Biochemical Society, tel: 0206-46351 (44-206, USA) for £16/$30. (8001)V

SEMINARS & SYMPOSIA

2nd International Symposium on Positive Strand, RNA Viruses

Vienna, Austria, June 26–30, 1989

Satellite meeting: WHO Review on the development of dengue, Japanese encephalitis and other flavivirus vaccines: June 24-25, 1989.

Contact: Dr. F.X. Heinz, Institute of Virology, Kinderspitalgasse 15, A–1095 Vienna, Austria. Tel: 222/431595 Fax: 222/432161 (W5640)M

PROPOSALS

UKCCCR PROGRAMME ON RADIATION AND CHILDHOOD CANCER

CALL FOR RESEARCH PROPOSALS

Grants are available from the United Kingdom Coordinating Committee on Cancer Research (UKCCCR) for research projects primarily in laboratory-based experimental biology with the following objective:

To ascertain whether in the context of exposure to ionising radiations, there exists any special sensitivity or hitherto undiscovered mechanism that would give rise to a higher incidence of childhood cancer, including leukaemia, than would be expected on the basis of current risk estimates.

The five-year programme will be implemented and independently directed by the UKCCCR with funding provided by the Atomic Energy Authority, British Nuclear Fuels and the Central Electricity Generating Board. The UKCCCR has a broad interest in the causation of cancer including leukaemia. This is being explored in relation to radiation through its recently convened Radiation and Cancer Subcommittee, and this programme has resulted from that interest.

The programme is primarily directed towards basic research into the biological mechanisms underlying risks associated with exposure to ionising radiations. However the Subcommittee has been set up with a broader remit, and there will be further discussions exploring questions relating to epidemiology. The Subcommittee will also, therefore, be interested in work in this area.

Further information on how to submit an outline application (not exceeding 1000 words) is available from **Mrs Jean Mossman, UKCCCR Secretariat, Medical Research Council, 20 Park Crescent, London W1N 4AL Tel: 01-636 5422 Ext 353).**

All sections of the scientific community, whether public or private, may apply. (7999)X

COURSES & CONFERENCES

Genetics Short Course
17-28 July 1989

30th Annual Short Course in Medical & Experimental Mammalian Genetics

Conducted by Johns Hopkins University and The Jackson Laboratory at Bar Harbor, Maine. Morning and evening lectures covering the field are supplemented by workshops, tutorials and demonstrations. Inquiries, applications to: **Dr. T. H. Roderick, c/o Training & Education Office, The Jackson Laboratory, 600 Maine Street, Bar Harbor, ME 04609-0800;** or **Dr. V. A. McKusick, 292 Carnegie Bldg., Johns Hopkins Hospital, 600 N. Wolfe Street, Baltimore, MD 21205.** (NW3053)C

UNIVERSITY CLAUDE BERNARD OF LYON AND THE ROYAL POSTGRADUATE MEDICAL SCHOOL OF LONDON

A LABORATORY COURSE FOR THE PREPARATION OF MONOCLONAL ANTIBODIES

to be held at: Faculté de Médecine Alexis Carrel, Université Claude Bernard, LYON, FRANCE.

from April 24th to April 28th, 1989

The course will be held in english with a group of lecturers having practical experience with monoclonal antibodies. Registration fee is 7,500 French Francs. This fee includes the hotel accommodation and lunches during the week.

Letters of application should be sent by March 20th, 1989, to the attention of **Ms Sophie PARMENTIER, Faculté de Médecine Alexis Carrel, Rue Guillaume Paradin, F-69372 LYON, FRANCE, Tel: (33) 78.01.31.62.**

Organizers: Dr. J.L. McGregor, INSERM U.63, Faculté Alexis Carrel, F-69372 Lyon, France, and Dr Mary A. Ritter, Royal Postgraduate Medical School of London, Hammersmith Hospital, du Cane Rd, London W12 0HS, UK. (W5506)C

ROYAL SOCIETY DISCUSSION MEETING

MARCH 1989

8 and 9 March: 'Molecular chemistry for electronics', organized by Dr P. Day, F.R.S., Professor D.C. Bradley, F.R.S. and Professor D. Bloor. **Speakers:** G.W. Gray, F.R.S., H. Ringsdorf, J.-C. Marchon, W.J. Feast, J.N. Sherwood, R.A. Hann, P. Hodge, D.C. Bradeley, F.R.S., D.J. Cole-Hamilton, J.O. Williams, A. Ledwith, O. Khan and J.S. Miller.

Registration details (no fee for attendance): Miss C.A. Johnson (ref. DMN/CAJ), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG. (Tel: 01-839 5561, ext. 278. Telex: 917876). (8025)C

INTERNATIONAL CONFERENCE

STUDIES INVOLVING NUCLEIC ACID RECOGNITION

17th-20th April 1989

Sheffield University, Sheffied, U.K.

An Independent Meeting of the Nucleic Acids and Molecular Biology Group of the Biochemical Society and the Royal Society of Chemistry

3rd GOBIND KHORANA LECTURER MORIO IKEHARA

Plenary Lecturers:

Steven Benkovic	(USA)	Thomas Krugh	(USA)
Marvin Caruthers	(USA)	David Lilley	(UK)
Jyoti Chattopadhyaya	(Swe)	Steven Neidle	(UK)
Marius Clore	(FGR)	Eiko Ohtsuka	(Japan)
Fritz Eckstein	(FGR)	Simon Phillips	(UK)
Angela Gronenborn	(FGR)	Wocjiech Stec	(Poland)
Claude Hélène	(France)	Dietrich Such	(FGR)
Robert Kaptein	(Netherlands)	Thomas Tullius	(USA)
		Michael Waring (UK)	

The Conference will focus on studies involving recognition between: Nucleic Acids and Nucleic Acids; Nucleic Acids and Proteins; and Nucleic Acids and Small Molecules.

Contributions on these themes are invited either as short oral presentations or as posters.

Attendance limited to 160 active participants. Bursaries available for graduate students. 2nd Circular and Registration Forms from: **Dr. G. Michael Blackburn, Department of Chemistry, The University, Sheffield S3 7HF, UK. Phone: 0742-768555 Ex-4474. Fax 0742-739826. Telex: 547216 UGSHEF.** (8021)C

IDIOTYPE NETWORKS IN BIOLOGY AND MEDICINE

APRIL 17–20 1989 Gennep, The Netherlands

Congress will cover:

Idiotypes in immunology
Idiotypes in regulation
Idiotypes in viral disease (with a special session on AIDS sponsored by BECTON DICKINSON BENELUX)
Idiotypes in bacterial disease (theme sponsored by PRAXIS BIOLOGICS INC., Rochester)
Idiotypes in parasitic disease (theme sponsored by DUPHAR BV, Animal Health Division, Weesp)
Idiotypes and cancer
Idiotypes and autoimmunity (theme sponsored by IDEC, Pharmaceuticals Corporation, La Jolla)

Invited Lectures by:

J. Bach	S. Ferrone	F. Melchers
M. de Baets	M. Fougereau	A. Nisonoff
C. Bona	M. Greene	A. Rees
N. Bos	D. Harlyn	P. Schuber
H. Bunschoten	G. Hoffmann	K. Stein
D. Capra	Ch. Janaway	K. Thielemans
P. Cazenave	R. Kennedy	J. Urbain
I. Claassen	H. Köhler	E. Weiler
D. Colley	T. Logtenberg	M. Zanetti
A. Coutinho		

Congress secretariat: **OBU Utrecht Congress Office, PO Box 14214, 3508 SH Utrecht, The Netherlands.**

Telephone: 030 523272 **Telefax: 030 522694**

LONDON SCHOOL OF HYGIENE & TROPICAL MEDICINE

(University of London)

MSc/Diploma in Human Nutrition

The London School of Hygiene and Tropical Medicine offers an MSc degree or Diploma course in Human Nutrition for professionals with medical, science or social science backgrounds who wish to develope an orientation to Nutrition, especially within developing countries. The course lasts for a year, starting in October. It consists of a two-term core course in nutrition, metabolism, physiology, statistics and epidemiology, health care, and economics, which is taken by all students, a third term option from Metabolic and Clinical Nutrition, Nutrition in Community Health, and Social Nutrition and Nutrition Policy, and a research project from July to September. A limited number of fellowships are available.

Information may be obtained from the **Registrar, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT.** (7987)C

MARINE BIOLOGICAL LABORATORY

1989 Summer Courses

BIOLOGY OF PARASITISM (June 11-August 11) Emphasizing the on-going convergence of molecular biology and immunology with tropical medicine, this course covers recent developments in research on parasites and parasitic disease. Laboratory work focuses on the general biology of parasites as well as applicable methods of molecular biology and immunology. Intended for advanced graduate and post-doctoral students as well as established investigators. Co-Directors: John E. Donelson, University of Iowa School of Medicine, and Carole Long, Hahnemann Medical College.

EMBRYOLOGY: CELL DIFFERENTIATION AND GENE EXPRESSION IN EARLY DEVELOPMENT (June 18-July 29) An advanced level lecture and laboratory course intended for graduate students, postdoctoral fellows, and other research scientists who wish a current treatment of major issues in the experimental analysis of developmental biology of invertebrate and vertebrate embryonic systems, and the diverse intellectual approaches now useful in this field. Director: Eric H. Davidson, California Institute of Technology.

MARINE ECOLOGY: APPLICATIONS OF MOLECULAR BIOLOGY TECHNIQUES AND MOLECULAR PROBES (June 18-July 29) Two three-week modules will provide an intensive experience for graduate, postdoctoral and highly qualified undergraduate students. Director: J. Woodland Hastings, Harvard University.

MICROBIOLOGY: MOLECULAR ASPECTS OF CELLULAR DIVERSITY (June 11-July 27) A six-week laboratory course intended for advanced students and established investigators who seek training in microbiological techniques and experience with a broad range of microbes, emphasizing anaerobes and their cultivation. Co-Directors: Ralph Wolfe, Universtiy of Illinois, and Peter Greenberg, University of Iowa.

NEURAL SYSTEMS AND BEHAVIOR (June 11-July 29) A lecture/laboratory course intended for graduate students, postdoctoral fellows, and established investigators combining state-of-the-art methods of neurobiology with the analysis of animal behavior, representing the interface between these two fields. Director: Thomas Carew, Yale University.

NEUROBIOLOGY (June 11-August 19) A ten-week advanced course for pre- and postdoctoral students providing lectures and laboratory experience in the issues and techniques of contemporary cellular and molecular neurobiology. Director: Arthur Karlin, Columbia University.

PHYSIOLOGY: CELL AND MOLECULAR BIOLOGY (June 11-July 22) A course for graduate students, postdoctoral fellows and established investigators who wish hands on experience with both standard methods to purify and characterize proteins, nucleic acids and other cellular components as well as several advanced techniques used to relate molecular structure to physiological function. The course will feature the importance of marine organisms available at Woods Hole as experimental systems in modern biology, and postcourse research with the staff. Director: Thomas D. Pollard, Johns Hopkins University.

Application Deadline: March 1, 1989

Partial financial aid is available to qualified applicants.

Closing Lecture	L. PHILIPSON, Heidelberg

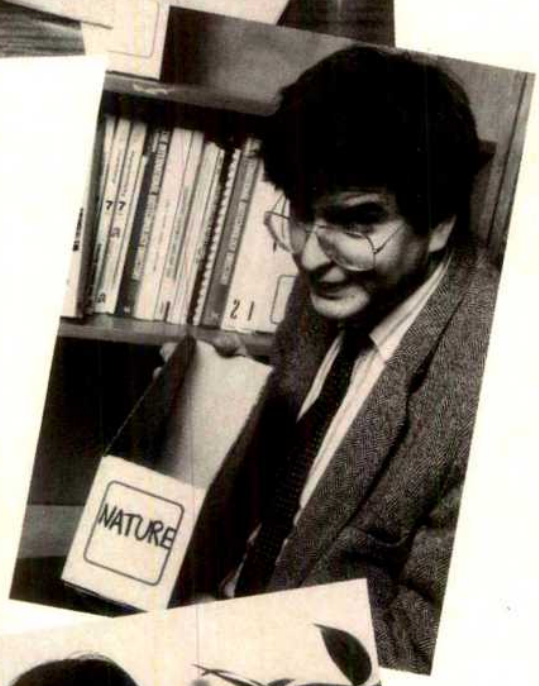
APPLICATION

The school is specially designed for young scientists: graduate students or Ph.D's. There will be plenty of time for formal and informal discussions. Participation is strictly limited to 80 students. Applications should include a C.V. and specific reasons for wishing to attend the school. A letter of recommendation may be added if such information is thought to be important in facilitating the selection process.

Application should be sent to: **Dr. V.E.A. Russo, Max-Planck-Institut für molekulare Genetik, Ihnestraße 73, D-1000 Berlin 33,** and should arrive no later than **28 February 1989.** Applicants will be informed by 1 May 1989 whether or not they were selected. There are no special application forms. If you wish to present a poster you must give the title in your application.

LOCATION: The school is residential. All participants will be accommodated in a conference center in the peaceful environment of Berlin's forest.

REGISTRATION FEE: none.



ROOM AND BOARD: DM 1,800. Room and board will be paid upon notice of acceptance to the school.

FELLOWSHIP: Many fellowships are available for young scientists for partial financial support. Write in your application what is the minimum amount of financial support (in DM) you need in order to participate in case you were accepted.

SPONSORSHIP: Max-Planck-Society, Fonds der chemischen Industrie, Bundesministerium für Forschung und Technologie, FEBS, the Senate of Berlin.

DONATIONS: Unilever, Ciba-Geigy, Amersham, Boehringer Mannheim. (W5719)C

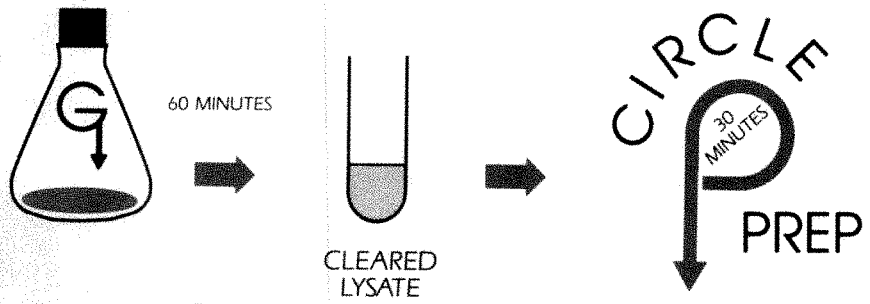
LET US Change Your Mind... ABOUT PLASMID PREPS

FORGET... 1 liter cultures → **THINK SMALL...** small volume cultures in CIRCLEGROW high density growth medium.

FORGET... enzyme digestions and organic extractions → **THINK SIMPLE...** isolate plasmid DNA without lysozyme, protease or RNase digestions; phenol or chloroform extractions.

FORGET... extended CsCl/EtBr isopycnic spins and... → **THINK FAST...** less than 90 minutes from cell pellet to purified plasmid DNA.



Think about it...Why expend the time and effort to isolate a milligram of plasmid DNA when you really need less than 5% of that amount for most cloning projects...Especially now that the CIRCLEPREP KIT allows you to get enough DNA to do what needs to be done quickly...90 minutes from cell pellet to purified plasmid DNA...50 to 100 ug of substrate-quality plasmid DNA that will cut and ligate every time...Think about it...but don't think too long.

CIRCLEPREP™

RAPID PLASMID DNA PURIFICATION KIT

patent pending

Isolate preparative quantities of enzyme substrate-quality plasmid DNA in 90 minutes.

CIRCLEPREP Kit, cat. #CP100

Kit contains all reagents necessary to grow cells, prepare cleared lysate and purify preparative quantities of enzyme substrate-quality plasmid DNA.

20 plasmid preps per Kit each typically yielding 50 ug of enzyme substrate-quality plasmid DNA per prep.

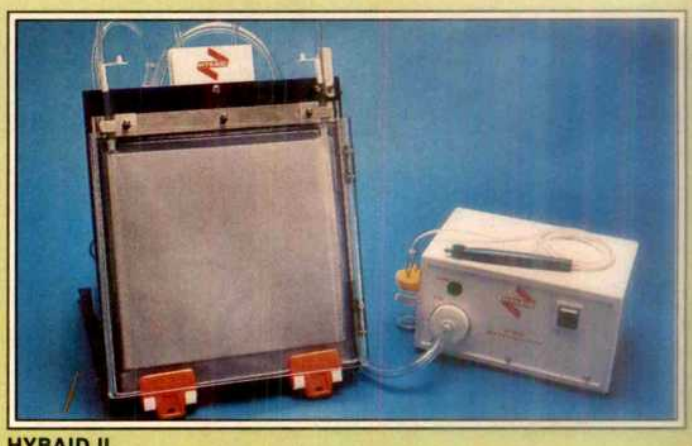
LOOK NO FURTHER
for the best in molecular biology equipment from HYBAID

Hybaid Ltd is dedicated to designing products that automate various commonly performed molecular biology techniques.



HYBAID 100
Microprocessor controlled blot generation and processing system. Automates all post blot procedures such as prehybridisation, hybridisation and washing. Ideal for all types of nucleic acid blotting.

INTELLIGENT HEATING BLOCK
Programmable heating and cooling block for raising, lowering and cycling the temperature of 24 samples. Restriction digests, probe denaturation and other processes may be performed automatically.

VACU-AID
Fast and convenient generation of blots – at least 16 times faster than capillary blotting and dispenses with the need for piles of paper towels. Vacu-Aid can handle larger gels than any other commercially available system.

HYBAID II
For the cost conscious laboratory. Hybaid II processes all types of nucleic acid blots with speed, safety and convenience.

The fungus *Akanthomyces aculeatus* Lebert growing on a leaf-mimicking moth as host, collected at Keravat, Papua New Guinea. Some *Akanthomyces* fungi have sexual states, but *A. aculeatus* relies on wind to disperse its dusty asexual spores. See page 262. Photo: Chris Prior, CAB International Institute of Biological Control.

THIS WEEK

AIDS drug

Soluble CD4, now undergoing clinical trials in patients with AIDS, has a therapeutic effect in an animal model for the disease in which rhesus monkeys are infected with an immunodeficiency virus. Page 267.

Plumbing at depths

What is the relationship between Hawaii's neighbouring volcanoes Mauna Loa and Kilauea? During the past 2,000 years Kilauea has erupted a range of lava compositions resembling historical Kilauea lavas at one end and Mauna Loa lavas at the other — perhaps magma from Mauna Loa invaded Kilauea's 'high-level' magmatic plumbing system. Page 257.

Image maker

These photographs were obtained by projecting an image onto a light-sensitive chemical

system that can act as a novel kind of image processor. Page 244.

Costing deer

The costs of gestation in the red deer, in terms of a reduction in the fitness of the mother, are negligible compared with those of lactation. This observation helps to explain why some mammals, including red deer, commonly produce more progeny than they can afford to rear, page 260.

Graduate quality

The proposition that better teaching is offered by universities also carrying out research is supported by data from the University of Salford. Commentary, page 223.

Improving on nature

Determination of the structure of the ribulose bisphosphate carboxylase active site should facilitate efforts to improve this key enzyme in cash crops by genetic engineering, page 229.

Body heat

Magnesium-26, produced by the radioactive decay of aluminium-26, has been found in non-refractory meteorite material; so this decay process may have been an important heat source for the melting of small planetary bodies in the early Solar System. Page 238.

Diamonds not forever

How old are the diamonds derived from the Earth's mantle? Potassium/argon isotope ratios suggest 6,000 million years — which would make them older than the Solar System. But this anomaly is explained if the diamonds trapped potassium-rich mantle fluids while they grew. Pages 226 and 207.

Protein kills

The 'killer' protein perforin attaches to target membranes by binding to phosphorylcholine, the predominant lipid head group of biological membranes, page 272.

Guide and Index

Author Index to Vol. 336, opposite page 290. Guide to Authors, Vol. 337, pages 96 and 132.

Nature® (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Magazines Ltd (4 Little Essex Street, London WC2R 3LF). Annual subscription for USA and Canada US$275 (institutional/corporate), US$125 (individual making personal payment). USA and Canadian orders to: *Nature*, Subscription Dept, PO Box 7663, Teaneck, NJ 07666-9857, USA. Other orders to *Nature*, Brunel Road, Basingstoke, Hants RG21 2XS, UK. Second class postage paid at New York, NY 10012 and additional mailing offices. Authorization to photocopy material for internal or personal use, or internal or personal use of specific clients, is granted by *Nature* to libraries and others registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided the base fee of $1.00 a copy plus $0.10 a page is paid direct to CCC, 21 Congress Street, Salem, MA 01970, USA. Superior biomolecule purification in half the time!

Preparative HRLC MA7 Q column

Analytical Mono Q column

For rapid, high resolution protein and nucleic acid purification, nothing equals HRLC columns from Bio-Rad. Our HRLC MA7 **non-porous** columns out-perform conventional **porous** columns by a significant margin.

What can the HRLC MA7 columns do for you?

- Rapid purification and regeneration even in preparative columns. Run times typically under 15 minutes for reduced biomolecule contact time.
- High resolution: minimal band broadening due to rapid, non-diffusion-limited kinetics.
- Easy scale-up: analytical to preparative columns using the same non-porous matrix.
- Full range of strong and weak, cation and anion exchangers.
- Excellent flow rate and chemical stability.

Compare for yourself. One chromatogram is the well known Mono Q porous type ion exchanger in an analytical column format. The other is our HRLC MA7 Q non-porous type ion exchanger in a preparative column format. Clearly, superior biomolecular purification can be yours in half the time using Bio-Rad's HRLC MA7 column chemistries.

You win both ways. Preparative HRLC MA7 columns for biomolecule purification, or analytical HRLC MA7 columns for methods development. Same superior resolution and performance—both at half the price of the competition!

Call us at 1-800-843-1412, or contact your local Bio-Rad representative to learn more about HRLC MA7 column chemistries.

Mono®Q and Mono® beads are registered trademarks of Pharmacia AB.

Comparison of HRLC MA7 beads and Mono® beads*

Parameter	HRLC MA7 beads	MONO beads
Packing material	Non-porous polymer ion exchanger	Porous polymer ion exchanger
Particle size	7 μm	10 μm
Maximum linear flow rate	600-3,000 cm/hr	300-2,100 cm/hr
pH stability	pH 2-12	pH 2-12
Pressure limit	100-200 bar	30-100 bar
Exchange kinetics	Rapid, non-diffusion limited (non-porous matrix)	Slow, diffusion limited (porous matrix)

*Based on manufacturers recommendations which vary with column dimensions.

Is your Protein Research on Track?

Electrophoresis with Titan® III cellulose acetate is a fast, inexpensive method for monitoring protein research. Separations are complete in minutes and cost just pennies per sample.

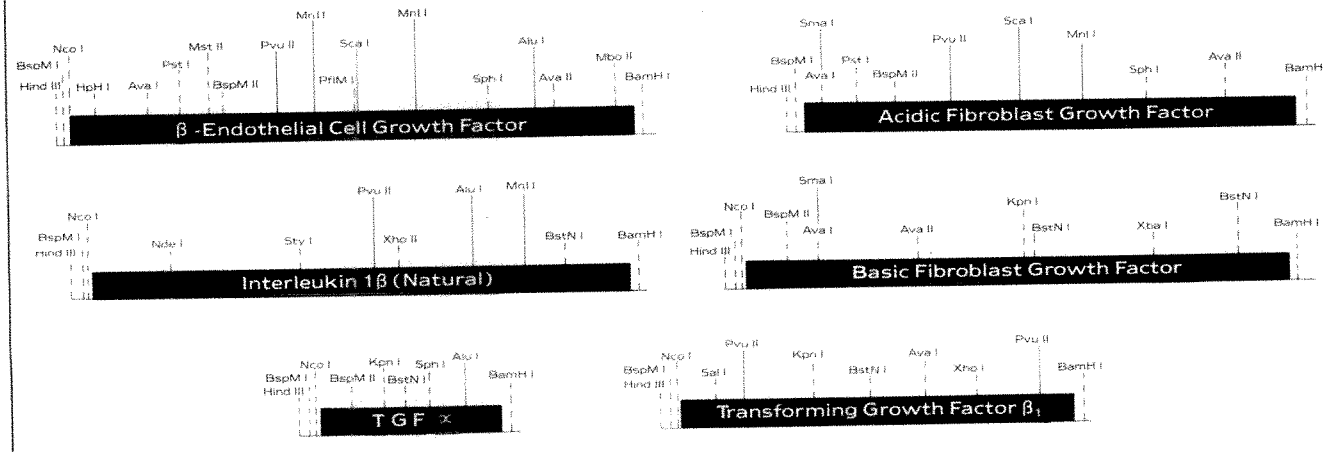
Titan III tells you quickly...

- Identity
- Purity
- Binding properties
- Approximate concentrations

Cellulose acetate electrophoresis is flexible, technically simple and requires tiny sample volumes. Migration is fast — only minutes to separate and stain. Patterns may be enhanced by general staining, immunofixation, transfer to nitrocellulose, autoradiography or many other techniques.

About Titan III Cellulose Acetate

- Available in several convenient sizes
- Indefinite shelf life
- Requires very little storage space
- Stable at room temperature



Other Applications for Researchers

- Monitoring column chromatography elutions
- Evaluation of samples in protein purification experiments
- Monitoring the progress of protein digestion by tryptic agents
- Assessing contents of cell extracts

For more information and details about packaging and pricing, call toll free 800-231-5663.

All in 1

Becton Dickinson Immunocytometry Systems has been the leading edge in Flow Cytometry technology for many years.

A dedicated team of experts is permanently engaged in developing research techniques into new clinical tests for Haematology, Immunology and Pathology.

Becton Dickinson offers completely integrated product packages for cytometry. These include a broad line of Leu monoclonal antibodies and other reagents, FACS brand flow cytometers for advanced research or clinical application, and CAS Quantitative Image Analysis systems. Highly automated data analysis software and controls complete the product line.

Becton Dickinson stays in at the forefront of research and product development and thus in finding total solutions to practical clinical problems. Extending the boundaries of our knowledge. Making them relevant to clinicians, for better patient care.

The New Horizon

Hyatt Regency/University of Miami
James L. Knight International Center
Miami, Florida • February 6–10, 1989

The 21st Miami Winter Symposium is the one conference of 1989 that will prepare researchers (both academic and industrial) for the life-science revolution of the 21st century—the human mind's discovery of itself. Don't miss that opportunity. Don't miss *Advances in Gene Technology: Molecular Neurobiology and Neuropharmacology*.

The Symposium offers an unparalleled program. No other gathering offers so many opportunities with such immediate access to fellow attendees, with this six-fold opportunity:

Advances in Gene Technology: Molecular Neurobiology and Neuropharmacology. Five days of lectures, more than 40 top researchers on the molecular biology of the nervous system.

The Second Annual Neural Systems Symposium: Computer Neural Networks. Two days of seminars on modern thinking on neural systems.

Focus Groups. Posters and extracurricular discussions spotlight key research issues from Alzheimer's disease to nerve-cell culture.

Workshops. Hands-on introductions to the latest research tools and concepts.

Placement Service. Job-seekers and employers will meet to fill positions in academia and industry.

Poster Sessions. A hundred authors on hand to present their most interesting results.

No gas, please, in the Middle East

Last week's conference on chemical weapons was ruffled by the flawed argument that Israel's adversaries need them to counter Israel's nuclear pretensions.

PUBLIC declarations of good intentions are cheap, decisions to put them into practice much more costly. This familiar truth seems to have been amply confirmed at last week's conference on chemical weapons (see page 199), held in Paris under the now-unfamiliar auspices of UNESCO. The 149 governments at Paris seem readily to have agreed that the best way to avoid the use of chemical weapons is to abolish them, but their joint declaration is deficient in two important ways. First, it fails to say much about the issue that has impeded the negotiations at Geneva for the past eight years, that of the verification of an agreement not to manufacture gases of the kind that can be loaded into munitions, although such a general conference cannot be blamed for that. Second, it fails to specify with clarity the dangers of the precedent set by Iraq during its recent war with Iran, when phosgene or a near relative seems to have been used against troops and civilian populations. Instead, it managed to give general currency to the notion that chemical weapons are a kind of natural counterpoise to nuclear weapons and should be legitimized as such.

That doctrine is profoundly mistaken, but seems to have been made with some force by Middle East states other than Iraq. So long as Israel has nuclear weapons (a plausible but untested assumption), is it not just that its potential adversaries should have access to chemical weapons as a kind of counterpoise? The argument is seductive, but false. The truth is that chemical weapons are not, except in the most symbolic sense, a counterpoise to nuclear weapons. Instead, they are a quite separate nuisance of a most serious kind.

Suppose that Israel is indeed a cryptic nuclear power, with a stock of more than 50 nuclear weapons — so much is the plausible inference from the harsh treatment by the Israeli courts last year of the technician from the Ramona nuclear complex who spilled the beans about plutonium extraction on the site. What use could Israel make of these weapons, which of necessity have not been tested? If Israel were in open conflict with its neighbours, and were so much in danger of defeat that the old Israeli nightmare of being driven into the sea seemed a reality, it is in principle possible that it could save itself from extinction by threatening to use nuclear weapons against the capitals of its adversaries. Earlier use of nuclear weapons, or the threat thereof, would do more harm than good to the Israeli cause — previously friendly governments would be compelled to withdraw support, and worse. But as things are, the possibility that Israel might be extinguished as an independent state would bring friendly governments rallying round long before Israel would rationally need to threaten nuclear retaliation. Thus Israel's nuclear weapons have a military function only in the extreme case that it has lost all its friends and is about to lose a terminal conflict. Militarily, Israel's nuclear weapons are a kind of national suicide pill — but their more immediate political utility is that of helping to cement deals with equally threatened governments.

Chemical weapons are a different kettle of noisome fish. Little is known of the value to Iraq of the use of phosgene in the recent war (somebody should find out), but it is likely to have been marginal in strictly military terms. Soldiers (and civilians) were killed in dreadful ways, but the most substantial damage to the Iranian troops, ill-equipped with protection against gas, is likely to have been psychological. Nerve gases, such as Libya is said by the United States to be preparing to manufacture, would have been more damaging, especially to the civilian population. Their military utility against well-equipped Israeli troops would again be marginal, while their large-scale use against the unprotected population of some Israeli city would bring down on the head of the user an insupportable torrent of protest and constraint. But that does not mean that the prospect that nerve gases will become more widely available is of no concern. These materials would evidently be of great value in surprise attacks against small groups of people, whether troops or not. And, given the ubiquity of the trade in arms, they would undoubtedly be used in other contexts (say, in hi-jacked aircraft) well outside the Middle East.

The argument that chemical weapons are a counterpoise to Israeli nuclear weapons thus makes no sense. That does not mean that the governments in the Middle East that have raised the issue would not be within their rights in demanding that Israel should trade its putative nuclear weapons for the political and military guarantees no doubt accompanying a peace settlement in the Middle East. It may also be prudent to accept last week's demand that the scope of the Geneva negotiations should be broadened to include at least Iraq (although, with 40 participants already, the negotiations are cumbersome enough). But the argument that chemical weapons should be counted as part of a poor country's right to self-defence is paper-thin, and should be denounced as such. To make it is dangerously irresponsible for the curiosity it will excite, not only in the Middle East. □

Industrial illogic

One of Britain's largest companies may disappear because, as in the parable of the talents, it has been over-thrifty.

WHETHER or not 1992 will see the eventual emergence of the true European common market advertised in the 1950s by the Treaty of Rome, the prospect that it might has caused turmoil in what is loosely called the electronics business. Two independent sets of motives have set off a wave of industrial reorganization. European companies, recognizing that there are more of them than the European market can comfortably accommodate, are anxious to consolidate their interests, preferably across European frontiers. Second, companies from outside the European Community are seeking to establish themselves within it, not least as an insurance against the chance that common-market Europe will chauvinistically protect its industries against competitors. The latest reorganization, mostly in Britain, also points to past errors by government and business which are all too likely to be repeated in the future.

The centre of the turmoil in Britain is the General Electric Company, or GEC, which resembles in the pattern of its activity the US company called General Electric or GE, but which is only a third as big. GEC as it is owes its existence to the convic-

tion of the Labour government of 1964 that Britain's four principal manufacturers of power generation equipment then were individually too small to compete internationally and collectively too many to survive; by coaxing and coercion, they were made to merge. The result is a business of extraordinary diversity — it will make you a domestic refrigerator, a computer-aided tomography scanner or a military radar — which has been kept intact and profitable only by the talented administration of its chief executive, Lord Weinstock.

But the conglomerate has failed to make a distinctive mark in any single field; Marconi, technically GEC's pride, conspicuously failed last year to develop an early-warning airborne radar to the British defence ministry's specification (the business went to Boeing instead). Another defect is that GEC first accumulated and has since kept liquid reserves of £1,500 million. But should not companies be thrifty, salting away money for a rainy day? Not if the implication is that they are so dismayed by the difficulties of making money in their own businesses that they ask the banks to try instead. The truth is that GEC has grown too slowly, almost certainly because it has put too little of its own resources into self-financed (as distinct from military) research and development.

Now there is a shake-up on the way. Three years ago, GEC awoke from its cautious lethargy and tried to buy the British telecommunications manufacturer Plessey, but was thwarted by the defence ministry's argument (to the Monopolies and Mergers Commission) that competition among defence contractors would be thereby curtailed. Last year, GEC instead merged its own telecommunications business with Plessey's, but then, this year, cheekily combined with Siemens of West Germany in a second attempt to buy Plessey. That has brought the roof down on its head. Plessey is working hard to recruit support for an attempt to take over GEC, which has been stampeded into merging many of its business with the comparable European businesses of GE of the United States.

The company's misfortunes are partly self-inflicted, partly caused by successive British governments. GEC, like Siemens and GE, began life with the commercialization of electricity a century ago, and became a conglomerate because electricity turned out to have diverse applications. But, for twenty years, GEC has been managed as a collection of separate businesses. That should have given it an advantage over its competitors in being able easily to hive off its activities to others prepared to back their conviction that they could do better with them by paying above the odds for the opportunity. But staying big has been counted more important.

Successive governments have fortified GEC in its complacency by their shortsightedness over defence research. The late Sir Ieuan Maddock, when chief scientist at the then Ministry of Technology, was forever asking why the lion's share of British governments' research and development expenditure should go for aerospace and associated electronics, mostly for the military. The decision to oppose the Plessey merger three years ago was falsely predicated on the belief that the British services must always be equipped by British manufacturers. It would have been wiser if the government had been pressing for a European understanding that the rules of European free trade should also apply to defence procurement. That has now become an urgent need.

Meanwhile, the air is filled with talk of what is called "industrial logic", mostly from people whose skill is the management of money. The calculation in 1964 that the British market could not support four power-generation manufacturers may have been correct, but "industrial logic" would have required that the four should compete with each other for survival; the outcome might have been a manufacturer capable of winning business from elsewhere as well as Britain. In other fields within GEC's present ambit — consumer electronics, for example — there can have been no danger of over-competition a quarter of a century ago. Putting nearly all of Britain's eggs into an oversized company has allowed West German, Italian, Scandinavian and Japanese manufacturers to win handsome prizes. The whole sorry episode should be a reminder to those who talk of industrial logic that success in industry is an empirical, not an abstract, business. The winners are those who succeed in competition with each other. Selling prices matter, but so do quality and performance, all of which are best ensured by intelligent research and development. □

Research in hazard

Last week's US budget promises generosity to science, but only the Congress can decide.

LAST week's valedictory budget from President Ronald Reagan is no less what had been expected of him than the intended tear-jerker of a speech he delivered to the United States a few days afterwards. For the budget, like the speech, has an olympian quality of detachment. Defence spending would increase (but modestly) and, within that, spending on the Strategic Defense Initiative would also be increased. The National Aeronautics and Space Administration would have the funds to build its space station, the Department of Energy would be able to make a start on the Superconducting Super Collider (and the clean-up of its military reactors) and general support for basic science (through the National Science Foundation) would also be increased. So how does the federal deficit affect these plans? On paper, it seems simple. If the cost of social programmes, Medicare and the like, is reduced by $30,000 million, the requirements of Gramm–Rudman can be satisfied for another year. The likelihood that a Congress controlled by Democrats will accept this neat solution may be small, but that will be for President George Bush to worry about when he takes over this Friday.

The danger in this process is that it puts the eminently desirable elements of the outgoing administration's programme in hazard to the uncertainties of a political process that has not yet begun. The next step is for the new president to say how he would amend the Reagan budget. Only then will the Congress begin to say how it will require the package to be changed. It would not be surprising (but par for the course) if the exact balance of the budget for the year beginning on 1 October is not known until after it has begun. In the circumstances, it is natural that the presidents of the US national academies (science, medicine and engineering) should have given the new administration their advice on how to manage science.

The Reagan adminstration's calculation that more spending on basic science would, in the long run, contribute to the competitiveness of US industry and the general wellbeing of society is correct, and in that spirit much has been done to increase, for example, the budget of the National Science Foundation. But some of the more expensive items in what is generally considered to be the science budget, the planned space station for example, are hardly science at all, while there is no known rational basis for telling in advance whether projects of that kind are more likely to yield economic benefits. A stronger science advisory apparatus at the White House could help to open such questions to discussion. Dr Frank Press's argument last year that the time has come when the scientific community in the United States must help to determine priorities is entirely apt.

But will it not be bad for science that one part of the community should be seen to be sceptical of another's pet projects? As in Britain a decade ago, the reality of government support for research and development is determined both by the sums of money set aside in budgets and by the value of what the money will buy when the time comes for spending it. No purpose will be served, in the United States, if promised spending is undermined by rampant inflation or by one of the other consequences of a continuing federal deficit on the scale bequeathed by Reagan to Bush. □

Scandal over Nazi victims' corpses rocks universities

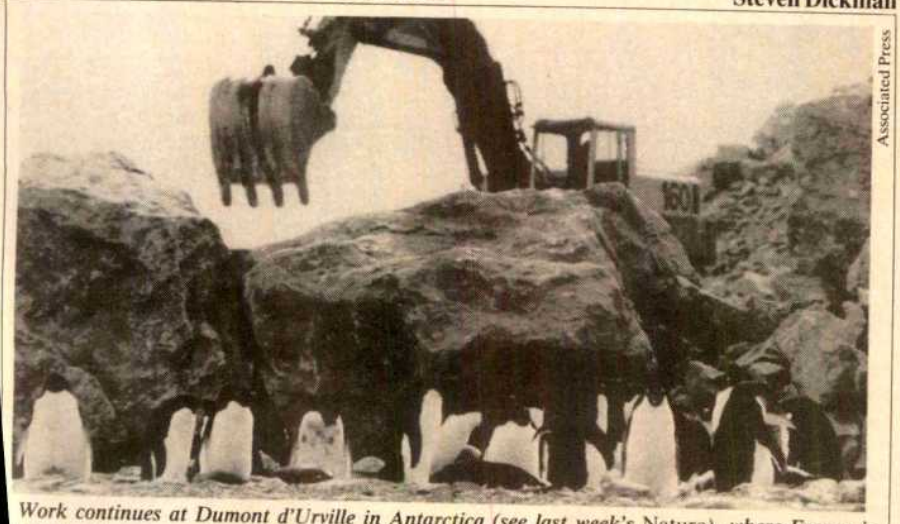
- Television programme opens old wounds
- New mood among medical students

Munich

ISRAEL last week protested to the West German government after a television company broadcast claims that tissue samples and skeletons from the corpses of victims of Nazi-era executions are being used for teaching purposes at West German medical schools.

The Israeli Religion Minister demanded that West German Chancellor Helmut Kohl immediately deliver all body parts from Nazi victims for a proper burial, although it has not been established that Jewish victims are involved. Kohl in turn has called on the universities to stop using any such remains and added that these practices "should have ended forty years ago". The medical schools at Tübingen and Heidelberg are at the centre of the row. Both are looking into the allegations although it is not expected that the charges will be conclusively proved in more than a few cases.

The allegations provoked a storm in West Germany when broadcast on the ARD television network. Although it is well known that, during the Nazi era, corpses for medical education were procured by universities from nearby execution sites, nobody seems to have asked about the origins of the slides and skeletons now being used in anatomy classes.



The practice of using the corpses of executed criminals began before the Nazis gained power, but the number of executions rose dramatically after 1933. The anatomy institute at Tübingen alone received 1,077 bodies from the execution site in Stuttgart between 1933 and 1945.

Tübingen University officials said they "had been lulled into a false sense of security" and believed that all remaining body parts from Nazi victims had been disposed of just after the war in a dignified manner. Both Tübingen and Heidelberg promptly began investigations but spokesmen for both universities pointed out that it will be virtually impossible to determine the origins of organs or individual bones in their medical collections.

Officials at Tübingen found four slides that had been prepared from two corpses of Nazi victims who were executed for political reasons. One was a woman of Polish extraction, the other a man presumed to be a German. In Heidelberg, three slides (out of about 1,500 in the collection) were found dating back to 1941 and 1943. The names of the people from whose corpses they were taken were not listed on the slides, but the indication 'decapitatus' indicates that the people may have been victims of Nazi persecution. A skull was also found that had been preserved by the 'preparator' of skeletons employed in the anatomy department from 1937 to 1946. All four items were removed from the department's collection and will be cremated.

That the row has erupted now may be indicative of changing attitudes. The current generation of medical students is demanding a deeper evaluation of the Nazi legacy in West German medicine. One result may be further scandals to come.

Associated Press

Work continues at Dumont d'Urville in Antarctica (see last week's Nature*), where France is constructing a new airstrip. Greenpeace protestors are still occupying the southern end of the airstrip.*

Breaking ranks

THE pay dispute between academics and management in Britain's universities took a surprise turn last week when the head of one university made a pay and promotions offer to staff in an attempt to avert industrial action which is disrupting university examinations throughout the country.

The principal of the University of St Andrews, Professor Struther Arnott, offered all academic and related staff a pay increase of 5 per cent from January to March this year and from April to March 1990 conditional on any new national pay scales negotiated. He also offered to make 30 promotions over the next three years, at least 20 to the level of senior lecturer. The offer must be sanctioned by the university's governing body, next month.

The Committee of Vice-Chancellors and Principals (CVCP) was surprised by the move and fears that it may jeopardize the universities' negotiations with the government for extra money to finance salary increases for 1989–90. The Association of University Teachers will not accept the offer, arguing that a local solution will not solve a national problem. But it hopes the move will put pressure on the CVCP to speed up national negotiations. C.McG.

LA cools it

BIOTECHNOLOGY gadfly Jeremy Rifkin has turned his attention to global warming, with the result that before too long there should be pockets of green dotting the asphalt landscape of Los Angeles. Last week, Rifkin joined Los Angeles Mayor Tom Bradley at a press conference at which Bradley announced that the city would plant 2–5 million trees to reduce carbon dioxide emissions and break up "heat islands" that raise the local temperature.

The tree-planting exercise is an initiative of Rifkin's Global Greenhouse Network, a group made up of international public interest groups and legislators. Rifkin expects Los Angeles to be the first of a number of cities around the world to adopt the tree-planting scheme. J.P.

Czech explosives

THE Czechoslovak government, evidently embarrassed by reports that its explosive "Semtex" was responsible for the destruction of the Pan-American aircraft over Scotland last month, last week proposed an international convention on the certification and detection of explosives. The offer, made during last week's conference in Paris (see page 199), immediately preceded the visit to Britain of a Czechoslovak team to assist in the forensic investigation of the disaster. The proposed convention is intended to regulate the manufacture of explosives for legitimate purposes and would include guidelines for their detection and the prevention of their unauthorized disclosure. V.R.

Japan's ERATO programme found to be working well

Tokyo

JAPAN'S Exploratory Research for Advanced Technology (ERATO) programme was set up in 1981 as an experiment to try to break away from the rigid hierarchy of universities and stimulate the kind of creativity that many Japanese researchers think flourishes in the West. Last month, in its first-ever evaluation by a group of foreign researchers, many parts of ERATO pass with flying colours.

The greatest praise was reserved for the Quantum Magneto-Flux Logic Project (1986–91) led by Eichi Goto of Tokyo University, which is exploring the possibility of making ultra-fast computers using magnetic quanta. John Rowell of Bell Communications Research, who assessed the project, said he was amazed that such a "sense of rebellion" could be fostered within the confines of Japan's existing industrial and university structure.

He believes the project has achieved success, as exemplified by the demonstration of a variety of logic functions using single flux elements composed of Josephson junctions. Such progress could not have been made in the United States, he says, where expertise in Josephson junction technology has been allowed to "evaporate".

ERATO, which is run by the Science and Technology Agency's Research and Development Corporation, has financed 18 projects, most of them high-risk research with some potential for application. Two or three new projects are begun each year and funded for five years at $2–3 million per year. Except for the project head, no member of the 15–20 person project teams may be over 35 years old. Researchers are drawn from industry and universities and include several foreigners.

The new evaluation comes from the Japan Technology Evaluation Program, which is supported largely by the US National Science Foundation. The Perfect Crystal Project (1981–86) headed by Junichi Nishizawa, Tohoku University, which developed improved methods for growing perfect crystals of silicon and gallium arsenide, was another project judged "very successful". Edward Wolf, director of the National Nannofabrication Facility at Cornell University, said he was particularly impressed with the effective coupling of the project with industry.

Among the biological projects, the Bioinformation Transfer Project (1983–88) headed by Osamu Hayaishi, Osaka Bioscience Institute, which examined prostaglandins in the central nervous system and their role in biological information transfer, is given high marks by Dale Oxender, director for molecular genetics at the University of Michigan. Seven patents have been filed and the results may have important applications in the pharmaceutical industry, Oxender says.

Seen as successful, but less imaginative, was the Superbugs Project led by Koki Horikoshi of RIKEN, which aims at finding commercial applications for microorganisms that can thrive in extremes of pH, temperature or salinity. The Bioholonics Project (headed by Denichi Mizuno, Teikyo University) and the Molecular Dynamic Assembly Project (H. Hotani, Kyoto University) were seen as "comparable to similar efforts in the United States".

Nearly all evaluators noted that ERATO gives project leaders considerable freedom to spend money as they wish, in contrast to the bureaucratic regulations surrounding financial support from the Ministry of Education, Science and Culture, But university researchers who accept ERATO funds are almost invariably "cutoff" from Ministry of Education funds unless they are "politically powerful". And Rita Colwell, director of Maryland Biotechnology Institute, drew attention to the total lack of female scientists in ERATO and the lack of leadership opportunities for female scientists in Japan.

AAU issues guidelines on dealing with scientific fraud

Washington

NEW guidelines intended to help universities to find ways to "distinguish fraud from the honest error and the ambiguities of interpretation that are inherent in the scientific process" were issued last week by the Association of American Universities (AAU), a body that represents most big US research universities.

The guidelines come as public concern over scientific misconduct is increasing, carrying with it the possibility that the US Congress will introduce strict new legislation to control research. A key part of the thinking behind the guidelines is that "institutions ought to be held responsible for the conduct of their faculty", according to Robert Rosenzweig, AAU president.

The new guidelines are simpler and stricter than draft guidelines issued by the Public Health Service (PHS) in 1986 and by the National Science Foundation in 1987. The guidelines do not accept that the resignation of a faculty member can close the books on a misconduct investigation, even though that action may provide an institution's simplest way to avoid public scandal. And once a conclusion has been reached, the institution should discharge its responsibilities to "the public, the sponsors of research, the scientific literature, and the scientific community".

The guidelines take up two of the commonest criticisms of misconduct investigations: that they take too long and that they can cause greater harm to the complainant than to the guilty.

A preliminary inquiry should be completed within 30 days and a full investigation, if warranted, within 120 days, although an institution may "acknowledge formally" that the nature of the case makes it impossible to meet the deadline. The guidelines acknowledge that "younger, less senior people are particularly vulnerable" when making accusations of misconduct, and urges that complainants be protected.

Little is made of another common criticism, that internal investigatory committees are inevitably under pressure to save face for the institution involved.

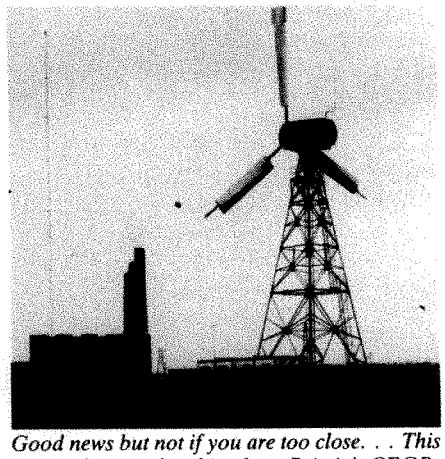
The new guidelines have been sent to all of AAU's 54 member institutions who will decide for themselves if they wish to use them as the basis for dealing with research fraud. AAU member institutions between them receive 60 per cent of all research grants given out by the National Institutes of Health (NIH), but the PHS, which is responsible for NIH, has yet to complete its own guidelines. An official notice of "proposed rule making" was published four months ago, more than two years after initial guidelines were produced. The final regulations are unlikely to be ready before May.

Alun Anderson

Erratum

Contrary to a News item in *Nature* **337**, 7; 1989 it is Johann Deisenhofer who is now in Texas (at the Howard Hughes Institute, University of Texas Southwestern Medical Center, Dallas) and Hartmut Michel who has remained at the Max Planck Institute (in Frankfurt).

OECD report itemizes risks of renewable energy production



Paris

ENVIRONMENTALISTS have been campaigning for years to alert governments to the long-term risks of burning fossil fuels for energy production, but the so-called 'clean' alternatives of wind, wave, solar power and geothermal power are not without serious hazards, according to a report from the Organisation for Economic Cooperation and Development (OECD).

The report takes the "important positive aspects" of renewable energy use as given. But while the negative impacts of fossil fuels or nuclear energy may be long-term and planet-wide, those of renewables tend to be more localized and shorter-term. In most cases, they arise because renewable sources convert low energy densities and thus require huge collector areas. Hydroelectric power, which accounts for 21 per cent of energy production in OECD countries (1978 figures), like wind power, is not directly polluting, but may render large areas unusable for agriculture or recreation and can destroy local ecosystems.

Biomass, especially firewood, which accounts for about 20 per cent of energy produced in developing countries can, however, have serious environmental impacts. Apart from deforestation, with its risks of soil erosion, burning firewood can produce airborne, inhalable particles that may be carcinogenic, as well as greenhouse gases. Large-scale waste incineration, on the other hand, is only as clean as the material burned. If the waste stream contains plastics or chlorinated products, highly toxic and often halogenated compounds may be produced, including dioxin and hydrochloric acid.

If passive solar energy presents few risks, apart from the build-up of radon due to improved insulation, active solar energy panels contain potentially dangerous chemicals, such as biocides, rust-inhibitors and antifreeze that could pose a problem for disposal on a large scale, says the report.

Good news but not if you are too close. . . This was the first wind-turbine from Britain's CEGB.

Geothermal energy also poses risks. Hydrogen sulphide and benzene are almost always associated with high-temperature geothermal fluids in large volumes and there is also an unknown risk that reinjected geothermal fluids could induce seismic activity — and most geothermal sites are in sesimically active regions.

Environmental Impacts of Renewable Energy. The OECD Compass Project. OECD 1988.

Reactor restarts *sans* repair

Paris

THE French prototype fast-breeder nuclear reactor, Superphénix, is to be restarted after a 20-month shut-down, even though its leaking fuel-rod transit chamber has not yet been modified (see *Nature* **332**, 384; 1988). The news, published in the government archive *Journal Officiel* last week, follows an announcement by the Industry Minister, Roger Fauroux.

The decision was greeted with applause by the 200 employees at the reactor's Creys-Malville site, near Lyons. But ecology action groups in France and neighbouring Switzerland are outraged and will now seek legal help to try to shut down the reactor permanently.

Superphénix was closed in March 1987 when liquid sodium coolant was found to be leaking from a storage and transit chamber. Engineers from Electricité de France (EDF), the nationalized utilities company that runs Superphénix, found fissures in the inner lining of the chamber. They proposed replacing the sodium coolant with inert argon gas and then running the reactor without the transit chamber inner lining in place. As the core is already charged with fuel, says EDF, the reactor can be run safely for about a year without needing to use the transit chamber. In the meantime, the chamber can be modified.

Fauroux was planning to restart the reactor on 14 January. If there are no incidents, electricity generation could begin again in March.

Critics feel that it is irresponsible to restart the reactor with one of its original safety devices out of action. Should an accident occur within the core, the transit chamber is the only place where fuel rods can safely be stored. They argue that Superphénix is not actually needed for electricity generation and is essentially a full-scale simulator for engineers.

Environmentalists say the government's action is undemocratic. "The decision was designed to have a psychological impact, to demoralize the opposition", says René Longet, director of the Swiss Association for the Protection of the Environment. "Why cannot the French allow open debate on nuclear energy, like other European countries?", he asks. France appears increasingly isolated now that both Britain and West Germany have effectively abandoned their fast-breeder programmes. But France, too, is under internal pressure, mostly economic, and has shelved plans to build a sister to Superphénix. The Centre à l'Energie Atomique, however, remains adamant that it is essential to gain technical expertise at Creys-Malville.

Peter Coles

Indo–French agreement stresses vaccines

New Delhi

A MAJOR Indo–French agreement on medical research is due to be signed in February on the eve of the visit of French President François Mitterrand to New Delhi to open the year-long festival of France in India. The agreement will be between the Indian Council of Medical Research and the French Health and Medical Research Institute (INSERM).

Seven research areas will be covered: fertility and human reproduction, ophthalmology, nutrition, public health, epidemiology, virology, immunology and bioengineering. Collaboration will be on equal terms and will include exchange of scientists, sharing of information and the initiation of research projects. The agreement will continue the trend towards increased collaboration between India and France.

An Indo–French Centre for Advanced Research set up in New Delhi in 1987 has already given shape to 14 joint projects. It will soon have a building of its own, constructed by France and given to India as part of the festival.

Another collaborative venture for the manufacture of vaccines is taking shape. It involves the construction of a plant to mass produce vaccines against measles, polio and rabies, and a multiple vaccine, in Gurgaon, on the outskirts of New Delhi, by the Institut Merieux of Lyons. The plant will at first meet the demands in India and later be expanded to cater to neighbouring countries.

Collaboration on vaccine production is important in the context of India's mission to immunize all children against six diseases by 1992. Another plant for producing 100 million doses of oral polio vaccine is being set up at Bulandshar, 140 kilometres from Delhi, in collaboration with the Soviet Union.

Fuzzy computing felt to be the next step in Tokyo

Tokyo

JAPAN's Ministry of International Trade and Industry (MITI) has persuaded a vast consortium of Japanese companies to invest millions of dollars into establishing a new centre for research and development on fuzzy computing.

The decision to set up the facility, called the Laboratory for International Fuzzy Engineering Research (LIFE), was made at a meeting of MITI officials and industry representatives on 11 January. According to a report in the Nihon Keizai Shimbun (an economic newspaper), 42 companies — including Toshiba, Nippon Steel, Hitachi, and Toyota — will each contribute Y100 million ($800,000) to LIFE. The project, not run directly by MITI, will be chaired in alternating two-year shifts, beginning with Hitachi. The centre, scheduled to open in April in Kannai near Yokohama and expected to operate for six years, will be staffed by some 30 researchers drawn from industry and will conduct joint research with government national laboratories (for example, Tsukuba's Electrotechnical Laboratory) and universities (specifically, Tokyo Institute of Technology and Kyushu Institute of Technology). MITI also plans to collaborate with foreign universities and research asssociations in countries such as France, the United States and West Germany. Patent rights will be held by LIFE and licensed to non-members, but fuzzy algorithms will be made freely available.

Fuzzy computing is based on fuzzy set theory, first presented in 1965 by Professor L.A. Zadeh, a US mathematician at the University of California at Berkeley who is now chairman of the International Fuzzy Systems Association there. Whereas conventional digital computers operate on the binary system, fuzzy computers can form conclusions from imprecise data (such as 'faster' or 'not so hot'), treating such input as having a value somewhere in the continuum between zero and one. Proponents of fuzzy theory hold that these characterisitics will allow fuzzy computers to process information in a manner analogous to the brain.

Considerable research on fuzzy computing has already been carried out in Japan, and fuzzy programming on conventional computers is used to control train speed in a subway in Sendai, a city north of Tokyo. At Kumamoto University, Associate Professor Takeshi Yamakawa has developed a fuzzy microcomputer chip set in collaboration with Omron Tateisi Electronics Company. Of the two chips, the 'rule chip' draws inferences from indistinct data; the 'defuzzifier chip' converts inferred conclusions into analog numerical values. In September 1987, the US National Aeronautics and Space Administration (NASA) asked Yamakawa if it could use his technology in controlling attitude and docking in the space shuttle. Yamakawa is said to have agreed on condition that the chips be used solely in civilian applications. NASA is said to have complied. Sometime this spring — after NASA completes its evaluation — Yamakawa intends to commercialize the device.

"What we are interested in falls into three categories", says MITI spokesman Taizo Nishikawa, deputy director of the Electronics Policy Division at the Machinery and Information Industries Bureau, "fuzzy control, such as the Sendai system; fuzzy information processing; and fabrication of fuzzy hardware — for example, fuzzy chips — that will be used to evaluate our basic research in the first two categories."

"There is a very broad range of applications for fuzzy computing", continues Nishikawa. "Industrial applications include image processing, plant management, and robotic control. Social applications include medical diagnosis, weather forecasting and aeronautics control."

The scope of the industries from which member companies come is quite broad, as are their specific interests in fuzzy applications. In addition to the steel, electronics and automotive industries represented by the companies listed earlier, members include computer software houses, chemical companies, electrical appliance and consumer electronics manufacturers, transportation companies, an electric power utility, and — very unusual for a MITI technology project — a Tokyo securities firm.

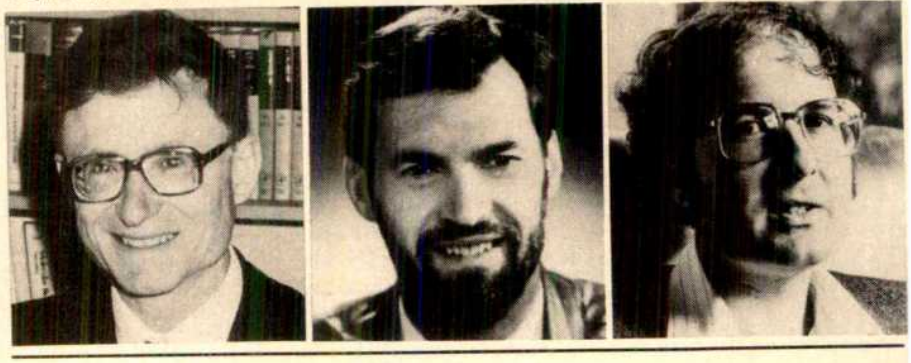
This year's prize season gets under way

London

ROBERTO Poljak of the Pasteur Institute in Paris, Walter Schaffner of the University of Zurich and Gregory Winter of the Medical Research Council's Laboratory of Molecular Biology in Cambridge are to share the 1989 Louis Jeantet Prize in Medicine, awarded for outstanding biomedical research in Western Europe. All three are selected for their contributions to immunology, and each will receive about one-third of the £0.75 million prize, plus £30,000 pocket money.



Poljak is cited for his contributions to solving the three-dimensional structure of antibodies, and will use his prize money to improve the computing and graphics power available to his group, and for new area detectors for his X-ray diffraction equipment. He hopes to solve the structure of a lysozyme idiotope–anti-idiotope complex. Schaffner will invest in an automated cell-microinjection apparatus and a fluorescence-activated cell sorter, both to enable his group to study the relevance of DNA methylation to the expression of genes, particularly the antibody genes for which he is cited.

Winter is rewarded for work on engineering antibody molecules, and hopes to finance a project he has been hoping to undertake for some years — to design an antibody molecule to bind specifically to an antigen of known three-dimensional structure. Winter has also won the 1990 Emil von Behring prize given by the Philipps University of Marburg. He wins the £6,000 prize for his contributions to the molecular biology of the development of human monoclonal antibodies.

The 1989 King Faisal International Prizes, each worth £0.5 million, have also just been announced. The medicine prize is shared by Robert Edwards of the University of Cambridge and Luigi Mastroianni of the University of Pennsylvania School of Medicine for work that has made human *in vitro* fertilization possible. Theodor Hänsch, who has recently moved from Stanford University to Munich University, and Ahmed Zewail of California Institute of Technology, share the science prize (this year physics) for their laser studies.

Poljak (left), Schaffner and Winter: the immune system pays handsome dividends.

Chemical arms exports embarrass Bonn

Bonn

On 11 January, as West Germany and 148 other nations resolved at a Paris conference to eliminate chemical arms worldwide, the first hard evidence began to appear linking West German companies to the alleged Libyan chemical weapons factory at Rabta. By now, as many as 30 firms have been implicated, although the West German government still insists that it has not seen evidence "admissible in a court of law." One day earlier, West Germany had announced new measures to restrict exports of "sensitive" goods of a military, nuclear or chemical nature. The restrictions came in response to a December scandal in which at least two West German firms are suspected of having delivered nuclear technology to Pakistan, India and South Africa in possible violation of the nuclear non-proliferation treaty.

The revelations about West German participation in the Rabta plant embarrassed the Bonn government. West Germany had been under pressure from the United States to investigate exports to Libya by Imhausen-Chemie GmbH, a company based in the Black Forest. A first investigation by tax authorities in Freiburg in early January cleared the firm.

Chancellor Helmut Kohl refuted the US charge, saying on 10 January that the United States had "put the Germans in the dock without giving us a chance to see the evidence." The next day, the news magazine *Stern* broke the news that the West German customs service had evidence against Imhausen and other firms. At the end of the week, the government revealed that the Federal Intelligence Service (*Bundesnachrichtendienst*) had informed Kohl in October that Imhausen might have violated export laws. The public prosecutor's office in Offenburg has begun a new investigation.

Regulating exports has always been a sensitive matter for West Germany, whose annual exports are worth more than DM 500,000 million. The new regulations put tighter controls on the export of technology and know-how in the nuclear, chemical and munitions areas. The government also recommends increasing the penalties for breaking export laws. The maximum prison term will be raised from three years to five years and the maximum fine from DM 500,000 to DM 1 million.

The government hopes to restrict future arrangements like the alleged Imhausen-Libya deal by lengthening the list of "sensitive areas," which previously included only the Soviet bloc and countries at war. Furthermore, the government recommends prosecuting Germans overseas found to have a hand in the production of chemical or biological weapons.

The opposition criticized the government measures while calling for a parliamentary investigation of the "poison gas affair" as it is coming to be called. Bundestag (parliament) member Norbert Wieczorek (Social Democrat) said it was hypocritical of the government to oppose exports which could lead to chemical arms production only when they go outside the European Community (EC). Wieczorek said that "there are not enough teeth" in the new regulations. He said that the fines discussed were "ridiculous sums" which would be considered by violators as just another operating cost.

Wieczorek admits that tougher controls do not guarantee that undesirable exports will stop. The volume of exports is so great, and the customs and regulatory authorities so understaffed, that many products will continue to pass through undetected. Only by increasing the penalties and the number of spotchecks will would-be violators be discouraged.

Perhaps the thorniest part of the problem comes in the area of "dual-use" technologies, such as the pesticide factory built at Samarra, Iraq, with the help of West German companies. It is has now been established that the factories produced poison gas, which Iraq apparently used during its 8-year war with Iran and on its own Kurdish population. But the guilt of the West German firms remains in doubt because it is unclear if they knew how their products would be used. An investigation into the matter is in its fifth year.

Another firm, Karl Kolb AG of Dreieich, has avoided prosecution under the current export laws by challenging the laws in court. Kolb was one of the companies charged with delivering equipment for the pesticide factory to Iraq. Kolb won the first court case; the government is now appealing.

Steven Dickman

Some good news some bad from Paris

Paris

The five-day Paris conference on chemical weapons closed on 11 January with all 149 participating nations declaring their readiness to "prevent all recourse to chemical arms, by eliminating them completely". But the declaration has already been criticized as not going far enough.

Britain, for example, would have liked concrete measures to prevent the proliferation of chemical weapons and an international commitment to punish governments that used them.

The declaration should, however, speed progress at the Geneva disarmament conference, whose 40-nation membership is trying to formulate a legally binding decree to ban the production and stockpiling of chemical weapons. The declaration asks the Geneva conference to redouble its efforts "urgently to resolve remaining problems" and to draw up a convention.

The plenary committee set up to draft the declaration had to compromise after heated exchanges among the participants. Iran, in particular, wanted Iraq to be pilloried. Syria defended possession of chemical arms so long as Israel has the nuclear bomb. Initial insistence by some other developing nations that there could be no chemical disarmament without nuclear disarmament was eventually dropped. In the final document, individual nations were not named, although the use of chemical weapons in recent wars is condemned.

There was further trouble when the South African foreign minister, Pik Botha, took the platform on 9 January. Many African delegates walked out, as well as one French delegate. But the biggest news from the conference remains the announcement that the Soviet Union will halt production of chemical weapons immediately and will start the ten-year process of destroying its stocks. The Soviet move includes an acceptance that international inspection will be essential to make compliance believable. But the view of the outgoing US administration is that the problems surrounding inspection are "insurmountable", given the ease with which conventional factories can be modified to produce chemical weapons.

Associated Press

Lone voice: Pik Botha spoke but few were there to listen.

Despite the obstacles to a complete treaty, the Paris declaration holds promise as a deterrent to further proliferation. The high profile surrounding the Paris meeting has already helped put pressure on nations such as West Germany, accused of supplying technology to Libya for chemical arms manufacture, to re-examine export controls (see above).

More money for science in Reagan's last budget

Washington

PRESIDENT Ronald Reagan delivered his final budget to Congress last week, a spending plan that seeks increased support for many areas of basic scientific research. Although it is tempting to view the lame-duck budget as 'dead-on-arrival' — because Congress and the Bush administration are certain to make changes — a complete overhaul of the $1,150,000 million budget is virtually unthinkable, and many of the proposals contained in it are certain to be approved once the new fiscal year begins on 1 October.

The Reagan years have seen substantial increases in spending for research and development. In a speech last week introducing the proposed 1990 budget, White House Science Advisor William Graham pointed out with some pride that between 1982 and 1990 "federal support for basic research will have increased by 56 per cent in real terms", reaching $11,200 million in 1990.

Graham used his budget remarks to criticize groups such as the National Academy of Sciences which have called for a stronger science adviser in the White House. He argued that "creating a science and technology 'tsardom' to direct what is to be done from the top down would be a disaster". Graham believes the best guidance for science comes from individuals doing research, and that a government's role is to support the best research.

The new budget calls for substantially greater spending on several big science projects; the National Aeronautics and Space Administration (NASA) budget requests $2,100 million for the Space Station, the Department of Energy (DoE) will request $250 million for continued development work on the Superconducting Super Collider (SSC), and the National Institutes of Health will be seeking $100 million for the human genome project.

Although the space agency's budget request is considerably more than that for the previous year, NASA administrator James Fletcher says the budget is a lean one, with no room for alteration. He does not hide the fact that the space agency had sought considerably more money, but had its request scaled down by the White House Office of Management and Budget (OMB). Although OMB approved a request for new funds for CRAF, the Comet Rendezvous/Asteroid Fly-by mission and its sister spacecraft Cassini, a planetary mission to Saturn, many prized projects have fallen by the wayside or been cut severely. There is no money for development of shuttle C, a cargo-carrying version of the space shuttle, and the Pathfinder advanced technology programme has been cut by more than half. In addition, OMB has decreed that $208 million must be raised from the private sector to cover expected costs, an ambitious target with which the agency is not happy.

The requested rise of $927 million for defence activities is an indication of the Energy Department's current preoccupation with getting the nuclear weapons programme back on track and bringing its ageing facilities into compliance with environmental regulations. Environmental safety and health programmes will also request significantly more money — $124.6 million in 1990 — but that is only a tiny fraction of the total cleanup cost at weapons facilities, estimated to be at least $50,000 million.

In addition to requesting support for the SSC, DoE's budget also seeks construction funds for a 6–7 GeV Synchrotron Light Source at the Argonne National Laboratory in Illinois and the Compact Ignition Tokamak at Princeton, New Jersey. There is also a request for $27.6 million for work on the human genome project, a $10 million increase over that for 1989.

The National Science Foundation budget seeks $2,150 million in 1990, a 14 per cent increase. Science education continues to receive emphasis, with a total of $190 million for precollege, undergraduate and graduate science education.

The National Institutes of Health (NIH) budget is scheduled for an additional 6.6 per cent for basic research. The total budget for NIH is set at $6,777 million, a modest 3.6 per cent rise over the current figure. This does not include a large increase in spending on research on AIDS, now listed as a separate item in the budget. The total request for federal AIDS activities within the Public Health Service is $1,600 million.

Defence research, still accounting for nearly two-thirds of all federal spending on research, rises to $41,024 million for the Department of Defense. The budget for the National Aerospace Plane is nearly $300 million. The Strategic Defense Initiative request is for $5,800 million, a $1,800 million increase over 1989. The Defense Advanced Research Projects Agency budget request is cut by nearly $166 million to $1,121 million.

Congressional budget committees will begin work in earnest on the budget once they have a clearer idea from President-elect Bush of what changes they can expect. But Albert Teich, one of the authors of a recent report for the American Association for the Advancement of Science on federal spending on research in the 1980s, says there are not likely to be big changes judging by past experience. Teich points out that in 1981, Democrat Jimmy Carter's final budget was filled with signals that the transition to a new administration would bring significant changes when Republican Reagan took over. Those signals are not present today, suggesting that changes to the Reagan budget proposals will be at the margins rather than the core of the spending plans.

Joseph Palca

UK meat research under threat

London

BRITAIN'S meat research could be severely curtailed next year by the threatened closure of the Bristol branch of the Agriculture and Food Research Council's Institute of Food Research, according to the Institution of Professional Civil Servants (IPCS), the union that represents more than half of the Bristol laboratory's 200 staff. The laboratory would be just the latest casualty of the government's policy to withdraw support from near-market research, for which it says industry should pay. The institute's director, Douglas Georgala, confirms that one of the three branches will close, but says no decision has yet been made as to which.

Many AFRC laboratories are suffering as a result of the reduction in contracts from the Ministry of Agriculture, Fisheries and Food, but the meat research laboratory has been hardest hit: its budget of £3.2 million is being halved over three years. The IPCS says efforts by the staff to become independent from government financing and secure contracts with industry are now being blocked: contracts between researchers and the Meat and Livestock Commission have been reduced from three years to two; contracts with industry and government through the LINK food-processing sciences programme will be restricted; and researchers are being prevented from submitting projects to FLAIR, the European food research programme. All these are signs, members of the Bristol laboratory believe, that their institute has been earmarked for closure.

Georgala says every effort is being made to help researchers secure contracts with outside bodies, but a temporary hold on international activities is necessary because the institute does not want to make commitments it may not be able to fulfill. He says the institute's activities will have to be cut back and is preparing a plan to implement cuts which will be presented to the AFRC in the next few months.

Closure of the Bristol laboratory will signify the end of meat research in Britain says the IPCS, and the effect on the meat products industry, worth £8,000 million per annum, will be disastrous.

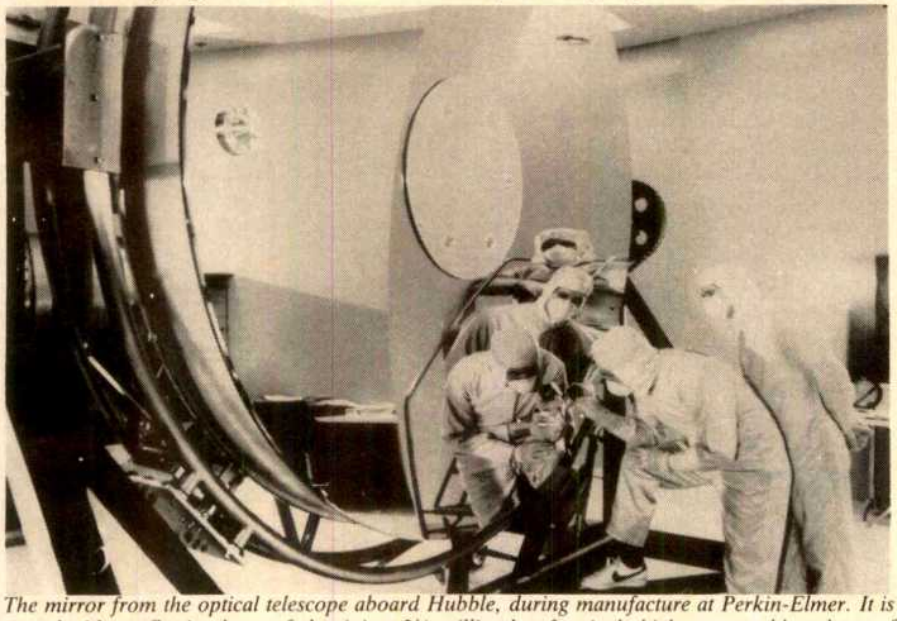
Christine McGour

Hubble telescope delays prove a boon for some

Berkeley

ALTHOUGH frustrating, the three-year delay in launching the Hubble Space Telescope has proved a boon for at least one of the mission's scientific teams. During ground testing of the faint object spectrograph (FOS), project manager Larry Randall says "fundamental problems" were found that were causing 10–30 per cent reductions in the light-gathering capability of the blue-side and red-side spectrographs. Tests of the instrument's optical alignment revealed a 'cat's eye' where there should have been an unbroken disk of light.

Randall received permission to open the instrument in late 1986. Inside, he discovered insulation and baffle material hanging in the light beam. And pieces of black tape and a rubber glove were loose within the instrument where they could stray into the light path in a microgravity environment. Randall also found that the instrument did not have the proper optical alignment, a problem he thinks may have been caused by the unfamiliarity of the instrument's contractor — Martin Marietta — with proper alignment techniques. Lou Ripp of Martin Marietta who was involved with the FOS project, said through a spokesman that the company had made a mistake in not involving scientists more actively in the design from the start.



In the overhaul, the FOS light path was restored and the opportunity taken to fit a new detector for the red-side spectrograph. The detector uses recently declassified technology developed by a project member, Edward Beaver of the University of California, San Diego, that has been used in military night vision devices.

The Hubble Space Telescope is now in Sunnyvale, California, where it is in the final stages of ground testing for its December launch. Apart from the changes made to the FOS, the alterations of the telescope's other four instruments were limited to refurbishing of parts to lengthen the lifetime of instruments, and the replacement of a faulty power supply on the high speed photometer, according to Fred Wojtalik, project deputy manager.

The telescope will soon receive its new improved solar wings from the European Space Agency, modified not only to increase power levels by 15 per cent, but also to resist degradation by atomic oxygen encountered in low Earth orbit. The newly developed nickel–hydrogen batteries (*Nature* **326**, 630; 1987) are still in final testing, but if they do not prove suitable Wojtalik says the craft can operate with the batteries from the original design.

The last remaining major decision is whether the telescope will travel to Florida by air or sea. NASA (National Aeronautics and Space Administration) originally planned to ship the craft through the Panama Canal on an ice-breaker. But, because the ship's busy schedule would allow only a narrow time window for the trip, mission planners proposed to fly the telescope to Florida on a C-5A transport, in an Air Force container

The telescope will fly to its Florida launch pad in August unless next month's flight tests show that the Air Force container, which was built for other purposes, is unable adequately to support and protect the telescope, in which case it will go by ship in late spring. **Marcia Barinaga**

The mirror from the optical telescope aboard Hubble, during manufacture at Perkin-Elmer. It is coated with a reflection layer of aluminium 2½ millionths of an inch thick, protected by a layer of magnesium fluoride 1 millionth of an inch thick.

UK plans for astronomy and planetary science

London

A PLAN for Britain's research in ground-based astronomy and planetary science over the next 20 years is published this week by the Science and Engineering Council. It focuses on four projects. The main one is an extension of the MERLIN radio-interferometer, based at the Nuffield Radio Astronomy Laboratories at Jodrell Bank, by the construction of a new 32-metre radio-telescope at Cambridge. This will also enhance British participation in the European Very-Long-Baseline Interferometry Network; construction of the telescope, to begin this year, will cost £6 million.

The council also recommends that Britain seeks a 25 per cent share, at a cost of £2 million, in a new incoherent scatter radar at Spitzbergen in the Arctic and at least a 30 per cent share in a new 1-km gravitational radiation observatory. The council is seeking extra money from the Advisory Board for the Research Councils so that Britain can afford a greater share in the observatory and thus secure its siting in Scotland.

The fourth project in the plan is the construction of an 8-metre telescope optimized for both optical and infrared work. At a cost of £15 million over the next ten years, Britain would hope to have a 50 per cent share in the telescope.

The plan also identifies 17 smaller projects which may be selected according to available resources. £28 million is available for the programme until the year 2000, but the board says that development of the new facilities will require savings in existing ones; these will be made through creating more international partnerships, reducing operating costs and closing some facilities. It does not specify where the cuts might be made. Christine McGourty

Israeli satellite stars

Jerusalem

OFEQ 1, Israel's first satellite, burnt up after re-entering the Earth's atmosphere (over the Pacific Ocean) on 14 January, 118 days after launch. The 156-kg experimental communications satellite was expected to remain in orbit for only six weeks. Professor Yuval Ne'eman, head of the Israeli space agency, attributed the extended life span to the fact that Ofeq 1 (Horizon 1) reached "unexpected" altitudes, thereby encountering fewer particles in space. He said the satellite continued to transmit data on the Earth's environment and magnetic field throughout its orbit.

Ofeq II, a more sophisticated satellite due to carry a scientific payload, is being prepared for launch within two years. With Ofeq 1, Israel became the ninth country to launch a satellite. Lisa Perlman

Anonymous peer refereeing

SIR—Recent complaints about the flaws of anonymous peer refereeing (APR) have overlooked a crucial question: how has this system arisen? Why do authors and referees regard this practice as inherently fair, so that they never really question its ethical validity? The explanation may be an historically interesting example of the unnoticed substitution of values.

The roots of APR are likely to be found in a legitimate democratic perception of anonymous voting. Anonymous voting by, say, secret ballot, is valid when issues must be determined by anonymous majority vote, say the election of governments or departmental chairmen. Scientists as a group have a deep respect for democratic traditions. But judgement on a particular research paper is not within the domain of statistical counting and is not (or at least should not be) subjected to an anonymous peer vote. Is it possible that traditional sympathy for democratic traditions has led the scientific community spectacularly to overlook the inappropriateness of APR?

ALEXANDER A. BEREZIN
Department of Engineering Physics, McMaster University, Hamilton, Ontario, Canada, L8S 4M1

SIR—I should like to add my recent experience to the letters regarding anonymous referees from A. Thyagaraja (*Nature* **335**, 391; 1988) and J. B. Wright (*Nature* **336**, 10; 1988). During the past year, I have submitted three reports of theoretical calculations in an active field of research to journals in three different countries. The results of the calculations differed in one significant respect from those generally accepted and publication was refused in all cases. I have no quarrel with this but, as none of the referees was able to produce experimental evidence for the rejection of the results, it was frustrating that all the reports were anonymous.

In one case, I attempted to correspond with the referee through the editor, who refused to pass on my letter as this was againat the policy of the journal. Again, I appreciate that this policy is designed to give referees more freedom to speak their mind, but I would argue that, if referees are to remain anonymous, it should be possible for an author to communicate once through the editor, after which it is up to the referee to consign the communications to the wastepaper basket if he likes.

G.C. FLETCHER
Department of Physics, Monash University, Clayton, Victoria 3168, Australia

SIR—J.B. Wright (*Nature* **336**, 10; 1988) does not believe there is a single good reason for anonymous refereeing, and asks for opinions from other readers. For about twenty years, I have signed all my reviews. My strong feeling is that non-anonymity helps to keep reviews brief, helpful and relevant. Anonymous reviews tend towards rambling essays on epistemology or, worse, a reviewer's opinion, based on unpublished observations, that a particular detail is inappropriate.

Few editors even read unsigned letters. None publishes them. It is therefore inexplicable to me why scientists accept anonymous reviews of their work. Some more specialized journals already publish critiques if they make interesting points not covered in the article itself. *Nature* might try this with some major articles, at least*. The manuscripts would be much improved, and the general reader is likely to enjoy seeing other, informed points of view. Along with Wright, I would have no confidence in a referee who balks at being identified.

There is a further benefit that even the most insecure, but overworked, scientist might appreciate. Judging from a small database, it seems that insisting on having your name on all reviews substantially decreases the number of manuscripts you are asked to review.

STEPHEN ROTH
Leidy Laboratory of Biology, University of Pennsylvania, Philadelphia, Pennsylvania 19104-6018, USA

* For an example, see *Nature* **223**, 161 (1969). Editor, *Nature*.

NERC rundown

SIR—The November 1988 issue of *The Biologist* made public what has been known to the Nature Conservancy Council and its advisers for some time, that the UK Natural Environmental Research Council is proposing to run down the Biological Records Centre at Monkswood, a data centre of world renown. The marine science division of NERC has already closed down the long-term biological data series for the English Channel off Plymouth — called the 'Russell Cycle' — and is planning to stop the operations of the Continuous Plankton Recorder survey of the North Sea and eastern North Atlantic early next year. Both of these data series are of world-wide scientific interest, and, like the data held by the Biological Records Centre, provide important information on the effects, deleterious or otherwise, of man's influence on the biosphere.

An inescapable conclusion is that NERC is preparing to close down most of the existing biological recording and collection of time-series data. Such continuing studies have been criticized by research council staff and civil servants on the grounds that they are "open-ended" and prevent the more "flexible" approach required by today's government. In this context, 'flexibility' means the ability of NERC administrators to direct groups of researchers towards special topics currently deemed of popular or governmental importance. Such pop topics change every few years and research would thus proceed in a series of well-publicized short-term *ad hoc* projects. It seems that NERC officials have persuaded their council members to agree that biological recording is a low priority area unworthy of NERC support and that there is a plan in the United Kingdom to run down all biological work of environmental importance, especially in the marine field. It is time biologists started protesting loudly in public and began lobbying fellow biologists who have places on the research councils.

A. J. SOUTHWARD
Marine Biological Association, Plymouth PL1 2PB, UK

Folk deceptions

SIR—In his review of Paul Barber's book *Vampires, Burial, and Death: Folklore and Reality*[1], Roy Porter remarks: " . . . this Count Dracula figure, so familiar from the movies, bears scant relation to the traditional revenant who is so powerful a presence in Central and Eastern European folk memory. Examination of recorded sightings shows the vampire was quite different . . .".

As a biologist who is also interested in traditional folk culture, I have spent many years doing field work in the areas that make up Transylvania, yet I have never heard any mention of Dracula, vampires or even "revenants". And in his encyclopaedic survey of ethnohistorical concepts[2], T.A. Szabó Sr includes only a single reference to *drakuly* (meaning 'devil') and that in 1680.

I am inclined to think that the whole Dracula story is a projection of Western European, chiefly Anglo-Saxon, ghost tradition to a distant and mysterious land. That projection has been exploited in print and in movies, best — but not first — by Béla Lugosi, whose picture adorns Porter's review and who was himself a Transylvanian in a broader sense.

ATTILA T. SZABÓ
Department of Biology, Berzsenyi College, 9701 Sombathely, Hungary

What prospects for *perestroika*?

The Soviet scientific community seems to have won a substantial measure of freedom in the past year, but the underlying problems of the Soviet economy cast a cloud over change.

Moscow

NOT even the unseasonably warm weather (on at least two days last week, the snow was melting) can explain people's cheerfulness — indeed, most would prefer that the weather would be what it should be at this time of the year, crisp and cold. Much of the explanation is that things have indeed changed a great deal, and for the better. Most noticeably, people who a year ago had never been abroad now seem to be regular travellers to what is still called the West (but which includes Japan). For those not travelling, it is now possible to find periodicals such as the *International Herald Tribune* in the hotels, but shockingly out of date.

There have been notable changes in the regulations affecting scientific work, and in the conscientiousness with which they are carried through, that have simplified once-complicated tasks. On travel, for example, an institute director's decision is usually, now, sufficient.

Similarly, with the publication of research reports, the formal approval of manuscripts by the parent academy (always a formality, but a thief of time) has been abandoned. An institute's director can approve publication in a Soviet journal, but the state copyright board which formally exploits overseas the intellectual property of Soviet citizens must still approve of publication in foreign journals. The decision of at least one writer to defy the board's authority (on the grounds that he would earn more without its intervention) has even raised the question of how long that system can continue to apply to scientific articles (where, usually, no money changes hands).

This betokens a kind of permissiveness that is unfamiliar. While the limits of *glasnost* remain to be explored fully (by experiment) and defined (presumably by reproof of some kind), even those in authority who make no secret of their uneasiness at present trends are evidently diffident at making too much fuss. But Mr Mikhail Gorbachev's 2-hour speech to a gathering of intellectuals at the Kremlin on 7 January, which argued among other things for support and also for self-restraint, may suggest that definition may not be far away.

Meanwhile, people have more elections to occupy their attention. In at least some of the Soviet Academy's institutes, this will be the third occasion in a year in which researchers have been voting on each other's suitability for one or another function. Less than a year ago, institutes were nominating members of the special Party Conference, in October many were electing new directors, now they are nominating people to be deputies in the new constitution's scheme for a representative parliamentary system.

The idea is that the Soviet Union as a whole should elect some 5,000 people to a chamber of deputies that will, this summer, elect from its own number a body known as the Supreme Soviet (at present nominated and largely honorific) to consist of full-time scrutineers of government legislation. The Academy of Sciences has 25 seats in the electoral college (the Soviet Union's philatelists' society also has a quota), the Communist Party as such has 100, but other Party members will no doubt be elected as district representatives.

Academicians Andrei Sakharov and Roald Z. Sagdeev, in that order, seem to be well ahead among the nominations of individual institutes. It is generally believed that, if elected, each would be prepared to stand for the Supreme Soviet. The academy's candidates will be chosen at a meeting this week. There is some ribaldry that one institute, having nominated its own director, decided not to nominate Sakharov as well for fear of undermining its own candidate's chances.

Meanwhile, it is certain that science will be represented at a senior level in the electoral college. Academician G.I. Marchuk, president of the academy, Academicians V. Kotelnikov and Ye. Velikhov (both vice-presidents, the latter now also director of the Kurchatov Institute) together with two other members of the academy appear on the Communist Party's final slate of 100.

Sakharov himself seems gracefully to have made the transition from exile to statesman foreshadowed by his election to the praesidium (governing council) of the academy three months ago. Back from a first visit to the United States only in December, he has been, at the request of Mr Gorbachev, on a fact-finding visit to Nagorno-Karabakh (the Armenian enclave in Azerbaijan) and has caught the attention of the academy with a powerful speech on ecology. If there were still a vacancy as honorific head of state (Mr Gorbachev is now both president and Party general-secretary), Sakharov would surely be appointed instantly.

Not all elections have brought such comfort. There is, for example, the sad case of Academician G. N. Basov, awarded a Nobel Prize in 1964 for the development of lasers (jointly with Charles W. Townes of the United States and his own Moscow colleague A.M. Prochorov) and for many years head of the Lebedev Institute in Moscow.

Basov's star began to set when he was not elected as the institute's nominee to the Party conference. Now he has been succeeded at a reorganized institute (strictly, a federation of research groups) by Academician Leonid Keldysch (son of a previous academy president). The final humiliation is that Basov has not been nominated as a deputy by the national "science-awareness" organization (analogous to the British Association for the Advancement of Science) of which he is the president. Yet he is a vigorous and even kindly man, but lacks adroitness.

Is it possible that, unused to free elections, the Soviet Union equates success in particular elections as a proof of all-round competence (and vice versa)? For that matter, it remains to be demonstrated that the election of institute directors by the staff whom they will manage will always produce satisfactory results.

Elections apart, people are worrying about *perestroika*, the process meant to put the Soviet Union back on its feet. Some welcome the fact that *perestroika* has further emptied the shops of goods on the paradoxical grounds that complacency is the real enemy, but the lack of a clear economic strategy is daunting.

The abrupt change two weeks ago of the rules affecting cooperatives (a kind of euphemism for private businesses) is a more particular worry. Cooperatives making medical diagnostics (small-scale biotechnology companies) will in future be regulated by ministries, others (as in publishing) are forbidden. The origins of this change are obscure, but seem to embody general discontent with the high prices charged by the cooperators, and the consequent high profits.

Meanwhile, too many rubles chase too few goods, so much so that offers to exchange rubles for foreign currency have become almost indecently open. The chief danger for *perestroika* in these circumstances is that of instability. Stopgap foreign credits seem the only quick way out.

John Maddox

Protein structure

Polyhedra for helical proteins

Cyrus Chothia

THE principles that govern how α-helices assemble to form the structure of globular proteins have not previously been understood. But now, in a paper in the *Journal of Molecular Biology*[1], Murzin and Finkelstein present an elegant solution to the problem. Some time ago, these authors showed that the geometries of α-helices packed around a ball-like core can be described by quasi-spherical polyhedra. They went on to argue that the intrinsic properties of α-helices and of their packing surfaces would mean that all or most helical proteins would have a structure described by one of a small number of such polyhedra[2]. In their new work[1], they demonstrate that this is indeed the case.

Three general features of the α-helices found in globular proteins are used in considering ideal helix packings and the polyhedra that describe the geometry of these packings. First, helices have the general shape of cylinders; second, they pack together with one face on the interior of the protein and the other exposed to the solvent; and third, they pack around a central hydrophobic core whose diameter is the length of two residues. Three helices packed in this manner are shown in Fig. 1*a*.

Figure 1*b* shows how the geometry of this packing can be described in terms of a polyhedron. To construct this polyhedron, a sphere of radius 11 Å is first drawn from the centre of the packing. This sphere encloses the central section of each helix axis, and these sections form one set of the ribs of a polyhedron. The polyhedron is completed by another set of ribs formed by the connections linking the ends of the nearest helices (Fig. 1*b*). For the three-helix packing shown in Fig. 1*a*, the polyhedron constructed is the octahedron shown in Fig. 1*b*. Using this construction, the geometry of any packing of helices can be described by a polyhedron.

Murzin and Finkelstein argue that in real proteins the assemblies of helices must be as spherical as possible and that the helices are close packed with a similar number of contacts. The polyhedra whose geometries reflect these properties are those that satisfy four criteria: a convex surface; all faces triangular; all ribs the same length; and a minimal difference in the number of ribs coming to each vertex. Murzin and Finkelstein find that only one polyhedron can satisfy these conditions for a given number of helices if the number does not exceed six. For more than six helices there are no such polyhedra. Ideal three-helix packings are described by an octahedron, four-helix packings by a dodecahedron, five-helix packings by a hexadecahedron and six-helix packings by an icosahedron (see Fig. 1*c*).

Helices can be placed on the ribs of polyhedra in several different ways. Three helices fit on the octahedron in two different arrangements: that seen in Fig. 1*b* and its enantiomorph. Four helices can be placed on the dodecahedron, and five helices on the hexadecahedron, in ten different ways. Six helices can be placed on the icosahedron in eight different ways. (Note in these arrangements the direction of the polypeptide chain is ignored: a helix is just treated as a cylinder.)

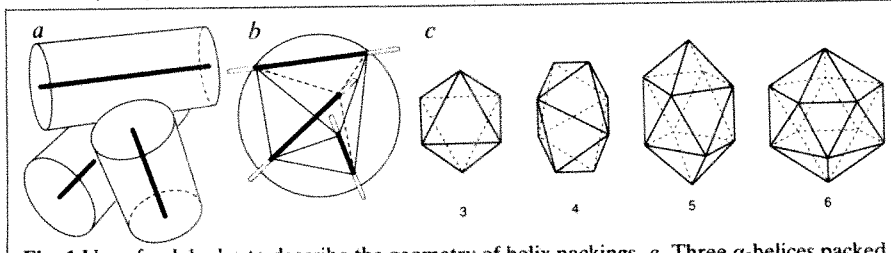

Fig. 1 Use of polyhedra to describe the geometry of helix packings. *a*, Three α-helices packed together are shown as cylinders with a diameter of 10 Å and with their axes as thick lines. *b*, The construction of the polyhedron that describes the geometry of this packing. A sphere is drawn from the centre of the packing with a radius of 11 Å. The parts of the helix axes enclosed within the sphere form one set of ribs of the polyhedron. The other set of ribs is formed by the lines joining the nearest ends of the helix axes. *c*, The quasi-spherical polyhedra for the ideal packing of three, four, five and six helices.

This 'quasi-spherical' polyhedron model describes the ideal packing of simplified approximations of α-helices. To determine if the model is relevant to real proteins, Murzin and Finkelstein compare the geometries of the helix arrangements observed in real protein structures with those expected from ideal models[1]. They make comparisons for all the proteins that contain helix packings and for which atomic coordinates have been published. In almost all cases there is a close fit between the helix packings found in these proteins and one of those in the ideal models. The larger proteins are formed by a combination of simple polyhedral packings. I show in Fig. 2 the three- and five-helix packings observed in actinidin[3] and thermolysin[4] and the corresponding ideal models.

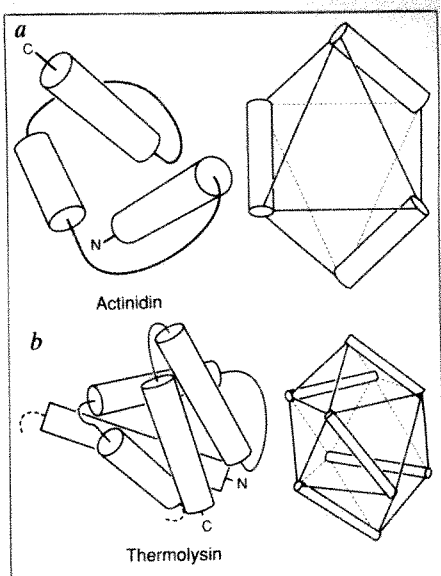

Fig. 2 Observed helix packing and ideal models. *a*, The three-helix packing found in actinidin[3] and *b*, the five-helix packing found in thermolysin[4]. The drawings were made by fitting cylinders to the atomic coordinates of the helices. The ideal helix packings whose geometry corresponds to that observed are shown on the right.

The positions and orientations of helices in the observed structures differ from those found for helices in the corresponding ideal model by 2 Å and 20° on average. The larger deviations occur in proteins where the spherical nature of the packing is distorted by the helices clustering not about a point but about a somewhat more elongated or flattened region.

The absence of ideal polyhedra for assemblies of more than six helices suggests that in the few proteins that contain such assemblies the packing is described by different types of models. One possible alternative would be the formation of layer structures by the helices[5], like those in proteins containing β-sheets[6,7]. The low-resolution structure of bacteriodopsin[8], for example, suggests that it is formed by seven helices packed in two layers.

Analyses of protein structures show that pairs of close-packed helices usually have their axes tilted in one of two directions: at angles of approximately −50° or +20°, arising from the ridge and groove character of helix surfaces[9]. The polyhedron models in which pairs of neighbouring helices are in orientations close to these values are those that most commonly correspond to the observed structures. There are two models for the packing of three helices, for example. That shown in Fig. 2*a* has the axes of the packed helices inclined at −60°, a value close to the preferred orientation of −50°, whereas in the alternative model the angle is +60°, which is some way from the nearest preferred value of +20°. Of the eight

non-homologous three-helix packings observed, seven are described by the first model and one by the second[1].

The quasi-spherical polyhedron model for the packing of helices has important implications for fields outside protein folding. Similarities in the structures of proteins are often taken to imply evolutionary relations even if there is no significant homology in sequence. Such a relation may exist. But Murzin and Finkelstein show that helical proteins can have very similar architectures independent of both sequence homology and chain pathway. Helix packings from non-homologous proteins but whose geometry is described by the same model appear very similar. Indeed, helix packings whose connectivities are very different but which fit the same model have sets of alpha carbon atoms that superpose with a root-mean-square difference in position of less than 2.5 Å. Values somewhat greater than this have previously been taken as clear evidence for evolutionary relationships. □

Computation

Breaking the matrix speed limit

Steve McCormick

MATRICES abound in the sciences. Many problems involving inter-related variables can be cast into equations that use the familiar array form of a matrix. For large-scale problems involving many variables, the matrix in question is often composed mostly of zeros — a so-called sparse matrix. To capitalize on this structure, the equations can usually be solved by iteration on a computer. Unfortunately, the asymptotic approach of the iteration to the solution can become extremely slow, a process termed critical slowing down. Among the many possibilities for combating this stumbling block, that now used by R. G. Edwards *et al.* (*Phys. Rev. Lett.* **61**, 1333–1335; 1988) in a model problem shows great promise.

Sparse matrices arise in the modelling of large, complex phenomena from virtually every corner of science, including fluid mechanics, structural analysis, molecular dynamics, geodesy, economics, image reconstruction and X-ray crystallography. A sparse matrix expresses known local rules that govern the behaviour of a system of objects describing the phenomenon of interest. These rules characterize direct interactions that emerge as numbers in the matrix array. The numbers in a given row quantify the interaction of a given object with all of its neighbours. The location of the relatively few non-zero numbers in the row indicate who the neighbours are, and their magnitudes indicate the degree of the interaction. The actual behaviour of the system can be recovered numerically by solving a set of equations defined by the matrix, but conventional methods for solving these equations often suffer from the debility of critical slowing down.

In their new work, Edwards *et al.* investigate this sort of trouble in the context of certain lattice systems that arise in the study of random-resistor networks, quantum chromodynamics and discrete Schrödinger operators. (For example, random-resistor networks are a paradigm for the conduction of current through composite materials. The non-zero matrix elements correspond to resistors randomly placed between neighbouring points of a lattice, and the idea is to determine the current at these points for a given external current supplied to the lattice.) The cure Edwards *et al.* use involves a relatively new method, called algebraic multigrid (AMG), the basic idea of which can be described as follows.

Conventional methods start with a given approximation to the state of the system, then attempt to make improvements by a sequence of sweeps that adjust the state of each object in the system, forcing the objects in their turn to obey the local rules. Critical slowing down occurs after a few such sweeps because these local adjustments can take an inordinate amount of time to determine the global state of the system. This is not unlike the trouble that an ant has in building or, better, rebuilding an ant hill. AMG avoids this trouble by making additional improvements on more global scales.

This is accomplished systematically by aggregating the objects into groups, automatically translating the local rules to apply to the aggregated system, then sweeping through these groups to make adjustments at the aggregated level. This approach gives an ant the power to work with clusters of sand for adjusting the coarse features of the hill, reserving the delicate manipulation of individual grains for the finer features. It gives the researcher the ability to determine the state of a system at a cost equivalent to just a couple of sweeps of the conventional method.

This approach is often relatively easy to develop, at least in principle. For lattice systems, there is usually one property (or variable) used to express the local rules among the objects, and this property can be treated as sort of a metric to determine appropriately how the objects and local rules should be aggregated. For example, in random-resistor networks, the resistance between two sites that are geometric neighbours can be interpreted as a measure of the intervening distance. Sites that are close in this sense can be grouped, and the aggregated rules can be determined by an averaging of the individual rules based on this measure. AMG computer software that automatically implements this approach has indeed been fairly successful for lattice systems, elliptic fluid flows and various other applications.

But for other complicated phenomena, development of the AMG approach can require very substantial research. For example, many systems use two or more properties per object to define local rules. In structural analysis, displacements for each coordinate and rotations for each pair of coordinates determine the state of the system. In developing an AMG scheme for a new problem of this type, just how such properties should be used to form distance measures is not always clear at the outset. But there have been very successful designs of AMG techniques for a broadening class of applications, including least-squares problems in geodesy, general fluid flows and various structural-analysis problems (see *SIAM Frontiers in Applied Mathematics* Vol. 3, ed. McCormick, S. F.; SIAM, Pennsylvania, 1987).

But this is just the beginning. Led by its pioneer A. Brandt and others, the multigrid concept has been making dramatic inroads into many new areas of science (see *Lecture Notes in Pure and Applied Mathematics* Vol. 110, ed. McCormick, S. F.; Springer, New York, 1988). Several challenging problems that were previously thought to be intractable now seem ready to fall before the multigrid axe. In the field of quantum chromodynamics, it is estimated that conventional methods could take ten million years or more to determine the mass of a proton. A novel multigrid approach seems to hold the promise of reducing this time to perhaps as little as a few hours. If such dramatic improvements can be made in this and other challenging fields, then critical slowing down may be well on its way out of scientific computation. □

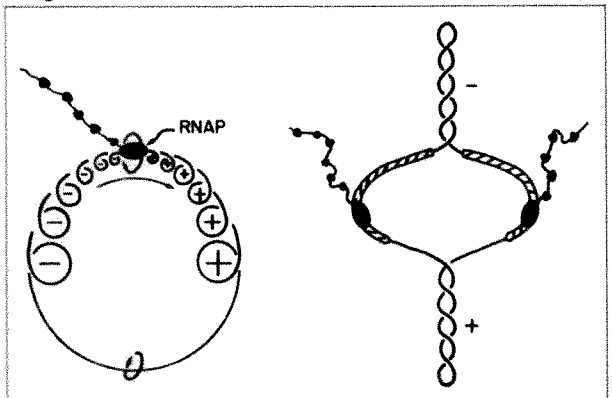
Gene transcription

Waves of DNA supercoiling

Maxim Frank-Kamenetskii

IF YOU walk to the window and rotate the double string used to draw the blind in a clockwise direction long enough to obtain a double helix, then insert a pen between the two strands and push it ahead without rotation, you would be making a mechanistic model of the transcription process: the pen, or RNA polymerase, moves along DNA, the interwound double string. From this experiment, it can be seen that while RNA polymerase translocates it should overwind DNA in front of itself and underwind DNA behind itself. In other words, DNA becomes positively supercoiled in front of RNA polymerase and negatively supercoiled behind it (see figure). Though an inevitable consequence of the DNA helical structure, this wave of supercoiling which moves with RNA polymerase seems fantastic. However, the elegant recent experiments by J. C. Wang and co-workers demonstrate that these waves of supercoiling actually exist both in prokaryotic and eukaryotic cells (Wu, H.-Y. *et al. Cell* **53**, 433–440; 1988; Giaever, G.N. & Wang, J.C. *Cell* **55**, 849–856; 1988). These data will surely change the general attitude to the biological significance of DNA supercoiling and to the importance of DNA topology.



Continuing the experiment with the string and pen, very soon the pen stops because the double string cannot be overwound any more. Thus, one has to suppose either that DNA and RNA polymerase rotate around each other, or that the cell can eliminate both positive and negative supercoils. One can hardly expect that a very long DNA molecule and a very bulky transcription machinery loaded in prokaryotes with an even bulkier translation machinery could rotate around each other. On the other hand, topoisomerases are known to be able to change DNA supercoiling. On the basis of these simple reasons, L. F. Liu and Wang put forward the concept of waves of supercoiling (*Proc. natn. Acad. Sci. U.S.A.* **84**, 7024–7027; 1987). But how can the wave of supercoiling be measured? Extraction of DNA from the cell, ridding it of proteins, causes the memory of the wave to be lost, as the wave of supercoiling does not change the overall DNA linking number. Although Wang and co-workers could not directly observe the wave of supercoiling *in vivo*, they unambiguously demonstrated its existence in experiments involving the inhibition of different DNA topoisomerases. Their most striking piece of evidence is the formation of positively supercoiled plasmid DNA in *Escherichia coli* when DNA gyrase is inhibited. In this case, topoisomerase I continues to remove negative supercoils, while positive supercoils, which are normally removed by DNA gyrase, are accumulated in DNA.

In contrast with the prokaryotic case, one cannot selectively cut off the topoisomerase activities which relax positive and negative supercoils in eukaryotes. Giaever and Wang overcame this difficulty by using yeast temperature-sensitive (*ts*) strains transformed by a plasmid expressing *E. coli* DNA topoisomerase I. This enzyme relaxes negative supercoils but cannot relax positive ones. In full agreement with the model, an endogenous plasmid extracted from cells grown under nonpermissive temperature when yeast endogenous topoisomerase was inactive, turns out to be significantly positively supercoiled.

These findings throw a totally new light on the biological significance of DNA supercoiling. Specifically, people had thought that DNA gyrase in *E. coli* serves as an enzyme which introduces negative supercoils into DNA. Competing with topisomerase I, it supports the native level of DNA supercoiling in the cell. Some held that by changing DNA supercoiling, gene expression could be regulated.

Now it can be seen that this picture, which was almost generally accepted, is really upside down. Indeed, DNA gyrase seems to eliminate positive supercoils rather than to create negative ones in *E. coli*. Native supercoiling is an irrelevant notion because actual local supercoiling may be highly positive, highly negative or negligible depending on the position of promoters, on the current position of RNA polymerase and on the relationship between the rate of RNA polymerase translocation and the efficiency of supercoil removal by the topoisomerases. Supercoiling depends on transcription to a far greater extent than transcription depends on supercoiling.

The findings of Wang and his colleagues emphasize the significance of the unusual structures in DNA (open regions, cruciforms, Z and H forms and so on) which form *in vitro* under negative supercoiling. These structures can form transiently in the negative domain of the wave of supercoiling (behind a moving RNA polymerase) and be trapped by specific proteins. Among other things, this could explain the transcriptional activation of replication and recombination. □

Formation of twin supercoiling domains during transcription. Left, a single RNA polymerase (RNAP) transcribing along a plasmid. Translocation generates a positively supercoiled domain (+) in front of RNAP and a negatively supercoiled domain (−) behind it. Right, when two opposing transcripts are present on the same circular DNA, the two supercoiled domains cannot merge by rotating the DNA alone; one of the transcription ensembles must be rotated as well. (From Wu, H.-Y. *et al. Cell.* 53, 433; 1988.)

THE BALD-HEADED CHIMPANZEE

THERE is no longer any room for doubt amongst naturalists as to the complete distinctness of the larger anthropoid ape of tropical Africa, the gorilla, from its smaller brother, the chimpanzee. But, on the question whether there is only one chimpanzee over the African continent, there is still much difference of opinion. The acquisition of the fine female specimen, known by the name of "Sally", by the Zoological Society in 1883, caused me to change my views. There can be no doubt that this animal, when compared with specimens of the ordinary chimpanzee, presents very essential points of distinction. The uniform black face and nearly naked forehead, render "Sally" conspicuously different from the many specimens of the common chimpanzee that the Society has previously received.

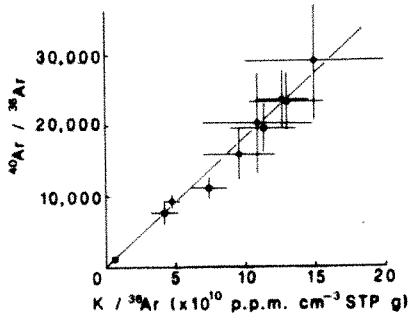
Geochronology

Diamond dating anomalies

Martin H. Dodson



DIAMONDS are particularly interesting samples of the Earth's mantle. Because of their unique combination of chemical stability and mechanical strength, impurities which they incorporate at their birth are protected almost indefinitely against interactions with the surrounding mantle. Some diamonds are known to be 2–3 thousand million years (Gyr) old[1,2], but direct dating of diamonds by the potassium–argon method has not been attempted until fairly recently[3,4], despite the great sensitivity of modern equipment for argon isotope analysis. Expectations, however, in geochronology are easily confounded; Ozima and co-workers, in a series of papers[4–6] culminating in the one on page 226 of this issue[6], show that forming diamonds can incorporate large amounts of 'excess' radiogenic argon in association with potassium, so that what began as a dating project has ended as a study of ancient mantle fluids.

Because of previous indications that excess argon would be a problem[3], Ozima and his colleagues decided to use an 'isochron' method (see figure) to date a suite of ten samples from Zaire called 'cubic' diamonds. These curious stones are polycrystalline aggregates with a rather fibrous structure and roughly cubic in shape, some having clear octahedral cores. It seemed likely that they are of uniform age and share the same initial argon isotope composition, essential conditions for the isochron method. In the event the stones yielded[4] a respectable linear array on the potassium–argon isochron diagram — indicative of uniform age — but a thoroughly unrespectable age of 6 Gyr, apparently making them 1.5 Gyr older than the Solar System.

Obtained from a single sample, this result would simply have been rejected as being due to excess radiogenic argon. The linearity of the isochron plot, however, made such an idea hard to accept, for it required that the excess argon was incorporated in exact proportion to the potassium. This seemed unlikely, because normally the contrast in chemistry between potassium and argon ensures that the Ar/K ratio in a new mineral grain is both lower (commonly zero) and more variable than in its surroundings.

A more fundamental explanation was therefore sought, and it was suggested[4] that the potassium had an anomalously high abundance of the parent ^{40}K. However, it was soon shown[5] that potassium in Zaire diamonds is isotopically indistinguishable from that found in any other terrestrial material. Thus the diamonds must either have incorporated a pre-solar component (diamonds have been found in meteorites) or have been isotopically contaminated in a very unusual way.

The question is now resolved in this issue[6] in favour of contamination during crystal growth, by mechanical entrapment of an argon-rich fluid. The clinching evidence comes from the argon–argon (or argon-39) method, in which samples are irradiated with fast neutrons, converting a small proportion of ^{39}K to ^{39}Ar. The ratio ^{40}Ar/^{39}Ar in gas extracted from the

Isochron plot for cubic diamonds from the earlier paper by Ozima and co-workers[4]. The ^{40}Ar and K contents of samples are plotted as ratios to their ^{36}Ar contents, which are assumed to be constant through time. Because ^{40}K decays radioactively to ^{40}Ar, data from samples formed at the same time, with uniform 'initial' argon-isotope composition (^{40}Ar/^{36}Ar), but *variable* K/^{36}Ar, would all fall on a straight line whose slope gives the age of the samples. The intercept shows the initial ^{40}Ar/^{36}Ar, in this case close to zero (−700 ± 900), suggesting that no ^{40}Ar was trapped in the forming diamonds. The ^{39}Ar data of Ozima and co-workers in this issue, however, show that these diamonds entrapped, as they grew, a variable mixture of fluids, one with high, fairly uniform Ar/K, another with low ^{40}Ar/^{36}Ar.

samples corresponds to the radiological daughter–parent ratio ^{40}Ar/^{40}K in the conventional method. The gas is usually extracted in stages while the sample is heated to successively higher temperatures; changes in apparent age during this step-heating procedure show differences between the locations of ^{40}Ar and ^{39}Ar within the sample. (Furthermore, during neutron irradiation ^{38}Ar is produced from chlorine and ^{37}Ar from calcium, so the concentrations of these elements may also be determined by argon isotope analyses.)

In their new paper, Ozima *et al.*[6] present step-heating analyses of four irradiated diamond samples. The 'age' from their isochron plot is again close to 6 Gyr, with little indication of changes during step-heating. More important, they find an excellent correlation of chlorine with ^{40}Ar. Ozima *et al.* point out that similar correlations obtained from fluid inclusions in the upper crust reflect leaching of argon and chlorine from crustal rocks. Evidently these diamonds provide evidence for analogous processes in the mantle, and the gases extracted from them consist of mixtures, in varying proportions, of a chlorine-free component with ^{40}Ar/^{36}Ar of about 340 and a component with ^{40}Ar/Cl of 8 or 9. Rather less convincing is the attempt, by means of a correlation diagram for radiogenic ^{40}Ar/K against Cl/K, to separate the ^{40}Ar into an excess component and an *in situ* radiogenic component (with a calculated age in the range 0–3 Gyr).

Navon *et al.*[7] (see also ref. 8) recently presented elemental analyses for Zaire cubic diamonds rich in sub-micrometre inclusions, interpreting them in terms of volatile-rich fluids roughly comparable with potassic magmas. Ozima *et al.* give potassium, chlorine and calcium abundances which are broadly consistent with those of Navon *et al.*, and provide complementary argon-isotope data. The significance of these inclusions for the understanding of mantle processes[8] would be hard to exaggerate, and it is clear that there must be further attempts to date them. Reported success in dating of fluid inclusions in crustal rocks[9] suggests that the Rb–Sr method could be worth a try.

Finally, do the problems encountered in dating of diamonds have serious implications for more conventional applications of the potassium–argon method? The answer is, probably not. In these diamonds the potassium–argon system is evidently dominated by a rather homogeneous ^{40}Ar-rich fluid which has been incorporated mechanically during crystal growth, mixed with small amounts of a low ^{40}Ar/^{36}Ar component. Thus the system does not satisfy one of the most fundamental requirements for successful dating, that the radiometric clock must be reset by a process of chemical differentiation between parent and daughter elements. In ordinary rocks and minerals the immense difference between the chemical properties of potassium and argon ensures that this condition can usually be satisfactorily met, with the likelihood of obvious inconsistencies in the data if it is not. □

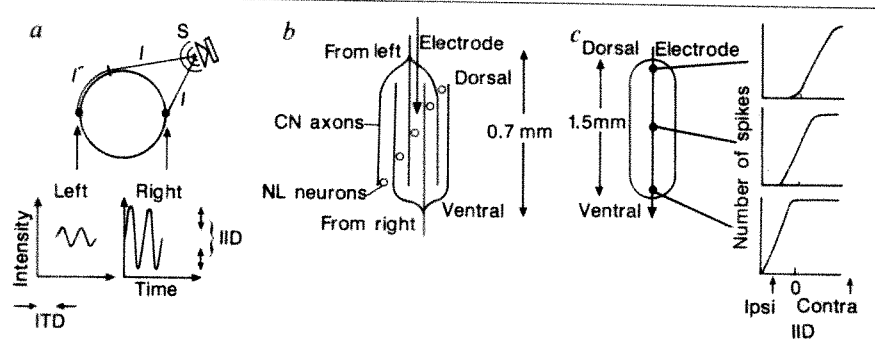
Vertebrate neurobiology

Sound localization mechanisms

David Moore

DIFFERENCES in the intensity and time of arrival of a sound at the two ears are well known to be the primary cues for auditory spatial localization in vertebrates (*a* in the figure). But despite many speculations, the neural mechanisms underlying these processes are not well understood. In two new reports[1,2], Masakazu Konishi and colleagues demonstrate the cellular and topographical neural organization underlying the first stages of processing of these signals in barn owls.

Barn owls are one of a small number of owl species to have evolved bilateral ear asymmetry. Such species are suited for studies of sound-localization mechanisms, because interaural time difference (ITD) contributes exclusively to localization in the horizontal plane (azimuth)[3] and interaural intensity difference (IID) forms the sole basis for vertical plane (elevation) localization[4]. The time and intensity pathways form separate streams in two divisions of the cochlear nucleus[5,6], the first synaptic station in the brain's auditory system. Neurons of the cochlear nucleus receive input from only one ear and so cannot detect ITD and IID. Detection therefore begins at the next level of the auditory system, where ITD processing occurs in the nucleus laminaris and IID processing in the posterior division of the ventral nucleus of the lateral lemniscus.



Jeffress proposed 40 years ago that ITD processing would be based on delay lines and coincidence detection[7]. He predicted that the length of axons derived from each ear and synapsing with binaurally innervated neurons should vary to compensate for physical time differences between the ears created by laterally positioned sounds. Thus, for a sound located on the right side of a barn owl's head, signals generated in the right cochlear nucleus would travel through longer axons to arrive at left nucleus laminaris neurons coincidentally with signals that had been generated later in the left cochlear nucleus. This model also predicts that nucleus laminaris neurons should be topographically arranged so that coincidence detection corresponding to different regions of space varies systematically across the extent of the nucleus.

Carr and Konishi now provide[1] direct evidence for both these proposals. By filling single axons from the cochlear nucleus with the tracer horseradish peroxidase, they show that axons derived from the two ears enter the nucleus laminaris from opposite sides and interdigitate (*b* in the figure). Physiological recordings from these axons reveal progressive shifts in the timing (phase) of responses relative to tone stimuli delivered to each ear. Through the depth of the nucleus laminaris (0.7 millimetres), timing shifts for stimulation of either ear are about 200 microseconds, consistent with the behaviourally relevant range of ITDs. But timing shifts for the two ears are in opposite directions, as predicted from the anatomy. Recordings from the dorsal side of the nucleus laminaris show a time lead for the ear on the same side as the recording, whereas ventral recording sites show a time lead for the other ear. Thus, single axons of different peripheral origins and different sensitivities to sound frequency form an orderly representation of ITD through the depth of nucleus laminaris.

The mechanisms underlying IID processing are not as well understood, either theoretically or empirically. Nevertheless, it has been recognized for many years[8] that there is neural sensitivity to IID. Most commonly, excitatory responses to acoustic stimulation of one ear are inhibited by stimulation of the other ear. The final level of the response is determined by the strength of excitatory and inhibitory input to each neuron. This, in turn, is determined partly by the intensity of the stimulus delivered to each ear and partly by factors intrinsic to the brain. For some neurons, inhibition dominates and may be complete when sound of equal intensity is presented to the two ears. For other neurons, sound presented to the inhibitory ear may need to be 20–30 decibels more intense than sound presented to the excitatory ear before any response suppression is observed.

In the ventral nucleus of the lateral lemniscus of the barn owl, Manley, Köppl and Konishi[2] show that neurons are organized topographically according to the IID for which their response is equally influenced by the excitatory and inhibitory ears (*c* in the figure). In the dorsal region this occurs for intensity differences where the input from the contralateral ear is more intense, and in the ventral region it occurs when the ipsilateral stimulus intensity is higher. Other systematic variations in response parameters across the dorso-ventral extent of the nucleus are correlated with this topography: excitatory and inhibitory response strengths and thresholds; spontaneous discharge levels; and sharpness of IID sensitivity. The results suggest that simple modulation of these parameters, particularly inhibitory response strength, can explain the observed topography.

Sound localization by humans and other

a, The physical cues for sound localization are established by a difference in the path length (*l'*) for sound reaching each ear, resulting in an ITD, and by the sound-shadowing effect of the head and outer ear producing an IID. Two cycles of a tone stimulus produced at the sound source (S) are shown as they would be recorded by microphones placed in the position of the ears. *b*, Schematic representation of axons from the left and right cochlear nucleus (CN) interdigitating within the barn owl nucleus laminaris (NL). Physical ITDs are offset by the time taken for spikes to travel through the depth of the NL from each side. According to their depth within the nucleus, the NL neurons shown receive coincident spikes from the input axons at different ITDs. Arrow, direction of electrode penetrations made by Carr and Konishi[1]. *c*, Electrode penetration (arrow) through the posterior part of the ventral nucleus of the lateral lemniscus (VLVp), showing (right) the responses to IID of neurons recorded at three depths. The IID at which balanced excitatory and inhibitory influences for each neuron was obtained is indicated. In dorsal VLVp, this IID is obtained when the contralateral ear intensity is higher (contra ↑). In ventral VLVp, the intensity at the ipsilateral ear needs to be higher (ipsi ↑) to give balanced excitation and inhibition (from ref. 2).

terrestrial mammals is almost certainly more complex than in the barn owl. Instead of acting over the same, relatively restricted frequency range to code for azimuth and elevation, time and intensity differences between the ears of mammals provide cues over different portions of the audible frequency range and both seem to be predominantly used for coding stimulus azimuth. Elevation cues in mammals are thought to result from sound–spectral transformations by the head and by the pinna, the visible part of the outer ear[9]. In fact, information derived from just one ear can, under certain stimulus conditions, lead to sound localization performance in humans that is as accurate as that achieved using two ears[9].

Nevertheless, several key nuclei in the mammalian auditory pathway bear striking anatomical and physiological similarities to those in the barn owl known to be involved in localization. A topographic representation of IID has been demonstrated in the midbrain of the cat, for example, and two-dimensional neural 'maps' of auditory space have been found in homologous brain regions of several owl and mammalian species[10]. It therefore seems likely that at least some of the mechanisms for processing binaural sound localization cues are common in many vertebrate species. □

Ocean Drilling Program

Breakup of Gondwanaland

*Leg 122 shipboard scientific party**

OLD, sediment-starved, passive continental margins are important for elucidating the thermal and structural processes that lead to rifting and continental breakup. These regions also contain clues about global palaeoenvironmental and climatic changes, as well as the record of sea-level fluctuations. There have been few deep-sea drilling studies of the older parts of continental margins even though their unique record reaches back to the Jurassic and Triassic, when there was only a single continental mass — Pangaea. Pangaea was split subsequently by the Tethys Ocean into Gondwana in the south and Laurasia in the north. We have studied the old Gondwanan passive margin of Exmouth Plateau, off the coast of northwestern Australia, to elucidate the evolution of rifting and drifting, in addition to the environmental changes that accompany and follow such momentous events.

The Exmouth Plateau is a rifted and deeply subsided fragment of continental crust, covered by more than 8 km of sediments, including nearly 1–2 km of post-breakup sediments. The present configuration of this region was initiated in the Late Triassic to Early Cretaceous (230–130 million years ago, Myr) by East-Gondwanan rifting between northwestern Australia, greater India and other Gondwanan fragments to the north. Leg 123 data suggest that whereas the northern margin of the Exmouth Plateau bordering the Argo Abyssal Plain had rifted before the Late Berriasian (140 Myr), the western margin bordering the Gascoyne Abyssal Plain developed during the late Valanginian (135 Myr) when sea-floor spreading was initiated there.

We drilled at six sites (Fig. 1). Four of these (759–761 and 764) on the Wombat Plateau yielded a composite record of sediments deposited during rifting in the Triassic (248–213 Myr) and during the Cretaceous (144–65 Myr) and Cenozoic (65 Myr to the present) following the breakup. The other two sites (762 and 763) reveal the Cretaceous to Cenozoic record of palaeoenvironmental and passive margin evolution of the western part of the central Exmouth Plateau. This record consists of a thick clastic shelf-margin wedge that prograded from a southern source area during the Early Cretaceous late-rift phase, and was there overlain by an Upper Cretaceous to Cenozoic pelagic (marine) sequence.

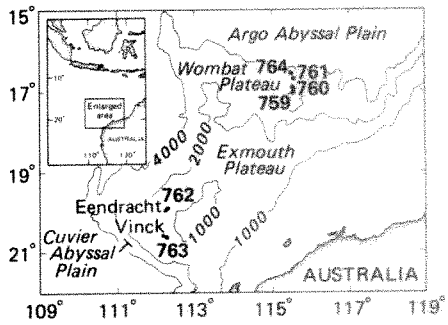

Fig. 1 Leg 122 sites (●) on the Exmouth Plateau. Commercial well sites are also indicated (•). Bathymetry given in corrected metres. (After von Stackelberg, U. *et al. BMR J. Aust. Geol. Geophys.* **5**, 113; 1980.)

Deep crustal extension and thinning of the northern Exmouth–Wombat Plateau area occurred during the Permian (286–248 Myr), and was followed by rifting during the Triassic. Carbonate rocks were deposited on the Wombat Plateau during the mid-Carnian (in the Triassic, around 228 Myr), in a southern embayment of a shallow Tethys Sea. The plateau periodically re-emerged until the Rhaetian (ending the Triassic, 213 Myr) when it developed a fully marine carbonate sequence. These carbonates resemble their coeval strata in the western Tethys region of the Alps. ▶

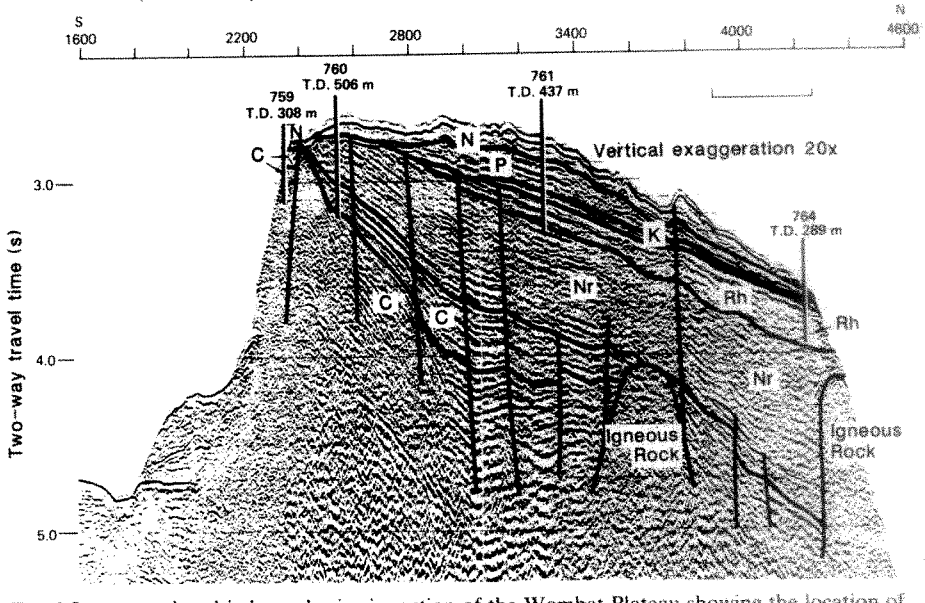

Fig. 2 Interpreted multi-channel seismic section of the Wombat Plateau showing the location of sites 759–761 and 764. Letters within the seismic profile refer to ages as follows: N, Neogene; P, Palaeogene; K, Cretaceous; Rh, Rhaetian; Nr, Norian; and C, Carnian. Scale bar, 10 km.

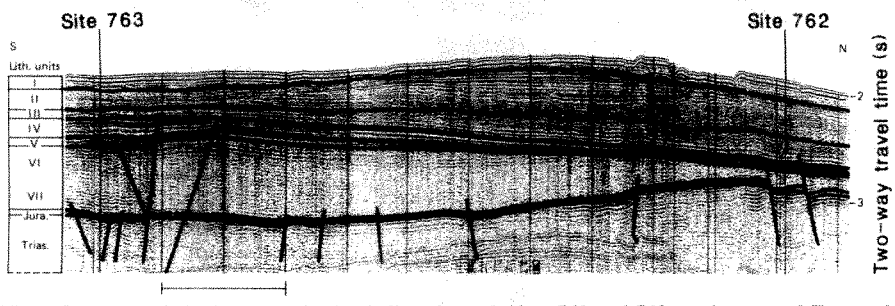

Fig. 3 Interpreted single-channel seismic line through sites 762 and 763 on the central Exmouth Plateau. Note thinning of the clastic wedge (units VI and VII) and thickening of the lower Tertiary sequence (unit II) from south to north. Scale bar, 7 nautical miles.

During the Jurassic (213–144 Myr), northward tilting raised Wombat Plateau above sea level again, and non-deposition or erosion prevented the preservation of Jurassic sequences before the onset of sea-floor spreading in the Argo Abyssal Plain. The plateau subsequently subsided rapidly during the early Cretaceous.

The time of breakup of the western and southern margins of the Exmouth Plateau is constrained by a major erosional unconformity, to around the end of the Neocomian (131–119 Myr), which agrees well with dating from sea-floor magnetic anomalies. Intervals of rising water depth are represented by condensed sections of thin glauconitic limestones and belemnite-rich mudstones. During the mid-Cretaceous (119–91 Myr), when the southern hinterland was drifting north-west with greater India, the southern supply of eroded rocks was cut off. Cyclic deposition of deep-water claystone during the middle to late Aptian (around 115 Myr) marks the onset of hemipelagic deposition (the 'juvenile ocean' stage).

A stagnant period of oxygen depletion produced a well developed black shale with up to 15 per cent organic carbon at the Cenomanian/Turonian boundary (91 Myr). Post-Cenomanian deposition became dominated by pelagic carbonate deposition, continuous in the northern part of the basin (site 762) and reaching site 763 to the south in the middle Eocene (around 50 Myr).

After isolating unconformities caused by tectonic events, we used a sequence stratigraphic approach to deciper sea-level fluctuations at each site. Our preliminary results indicate that there are important sequence boundaries on the Wombat Plateau between sediments representing the middle and late Carnian, at the Norian/Rhaetian boundary and in sediments of latest Rhaetian age, whose timing conforms well with global changes. Sequence boundaries recognized in the Lower Cretaceous of the central Exmouth Plateau also correlate well with global changes but indicate that the pattern of accumulation of deposits may need to be modified in regions of fast sediment supply. □

Evolutionary biology

Seed of destruction

H. C. J. Godfray and Paul H. Harvey

WHEN Jack Werren and his colleagues attempted[1] to select for the sex ratio in *Nasonia vitripennis*, a parasitoid wasp that attacks houseflies and related species, they found to their surprise that females producing only sons started to appear in the line being selected for male-biased sex ratios. They established by crosses using genetically marked flies that the trait (*psr*, for paternal sex ratio) is extra-chromosomally inherited. This was the first recorded occurrence of cytoplasmic inheritance through the paternal line of an animal. In their most recent work[2,3], these authors establish the nature and mode of action of *psr*, and provide an explanation for its evolutionary origin. The serendipitous discovery of what has been termed the most selfish genetic element that has yet been described offers the prospect of new insights into the structure and function of eukaryotic chromosomes.

Initially, it was uncertain whether *psr* was an infectious venereal disease which causes the death of female progeny, or a cytoplasmic factor transmitted to the egg during fertilization which causes it to become male. *N. vitripennis*, like other hymenopterans, has a haplodiploid genetic system with haploid males developing from unfertilized eggs and diploid females from fertilized eggs. As with many other hymenopterans, the female wasp produces a male-biased sex ratio when her sperm reserves are depleted, and a female-biased sex ratio in circumstances where her progeny tend to mate among themselves[4,5] or when an appropriate maternally inherited cytoplasmic sex-ratio factor is present[6]. The proportion of progeny carrying the *psr* trait was highest when a female-biased sex ratio was expected[5]. It therefore appeared that *psr* enters the putative female eggs at fertilization, converting the zygotes to males.

Cytological examination revealed that sperm carrying the *psr* trait enter and fertilize the egg as normal. During the first mitotic division, however, half the chromosomes appear clumped together in a dense mass of chromatin and do not participate in further cell divisions[2]. The embryo, with its now haploid chromosome complement, develops as a normal male wasp. Genetic marker studies reveal that it is the paternal genome which is eliminated.

Extra chromosome

In their new work, Nur, Werren and co-workers reason that *psr* might be discovered by identifying the DNA present in infected but not in uninfected males. They created a λ-phage genomic library from *psr* male DNA, and searched for clones that hybridized with radioactively labelled whole DNA from *psr* males but not with DNA from normal males. They found 36 such clones, and subjected several of them to restriction-enzyme analysis. It turns out that much of the *psr*-specific DNA is in the form of satellite-like, short tandem repeats, the most abundant sequence being 171 base pairs long. This finding is not compatible with the idea that *psr* is a virus or a transposon, but suggests that it could, after all, be a supernumerary chromosome because satellite-like DNA is characteristic of heterochromatized regions of chromosomes. Indeed, detailed cytological study reveals a small chromosome found only in *psr* males.

Supernumerary, or B chromosomes are fairly common in animals and some even show varying degrees of meiotic drive[7]. But the devastating selfishness of *psr* is unique: in a mating between a male bearing *psr* and a female, *psr* first destroys the chromosomes of its original host and then, in the next generation, those of its newly adopted host. Though much of the DNA in the B chromosome is in the form of tandem repeats, specific regions are known to code for a *trans*-acting factor involved in the super-condensation of the parental chromosomes. Analysing the mode of action of *psr* could reveal the mechanism of chromosome condensation, which is poorly understood.

Where does the B chromosome come from and what is its fate? There are now preliminary answers to both questions[8]. There are several cytoplasmically incompatible strains of *N. vitripennis*, and in matings between wasps from two such strains, the paternal chromosomes are broken down. But is is possible to recover fragments of partially destroyed chromosomes that display high transmissability through the male line but much lower

transmissability through the female[9]. Such a fragment is under strong selective pressure to change the sex of the female zygotes it normally finds itself in to more congenial male zygotes.

Method of spread

Once *psr* has evolved, it may spread. Werren points out[10] that if *psr* is transmitted by all the sperm of an infected male in a spatially unstructured population, the equilibrium frequency of *psr* is $(2x-1)/x$, where x is the proportion of eggs that female wasps fertilize. This means that *psr* will not persist unless $x > 0.5$, that is, unless female wasps fertilize more than half their eggs, which would mean producing a female-biased sex ratio in an uninfected population. *N. vitripennis* does indeed do this because its populations are spatially structured with mating occurring among the offspring of small groups of females, with consequent very high levels of local mate competition[11,12]. Although this female-biased sex ratio favours the spread of *psr*, another feature of spatially structured populations tends to hinder its spread: if all the females laying their eggs in a single patch (perhaps a localized population of housefly larvae) have mated with *psr* males, all their progeny will be sons who will die without mating. Theoretical models of the spread of *psr* in spatially structured populations indicate that persistence is possible only for intermediate levels of population subdivision[13].

Ironically, the persistence of *psr* may be markedly enhanced by the presence of maternally inherited cytoplasmic factors that cause female-biased sex ratios[13], two of which are known from *N. vitripennis*[6,14]. No systematic search for extrachromosomal sex-ratio factors has been undertaken in Hymenoptera other than in *N. vitripennis*. Of all groups with variable sex ratios, parasitic wasps were thought to be the best understood: perhaps there is a whole new level of complexity yet to be explored. □

Raymond Arthur Dart (1893–1988)

RAYMOND Dart died in Sandton, Johannesburg, on 22 November 1988, almost 64 years to the day since he had received the chunk of sandy limestone containing the Taung skull that was to create his reputation. Dart recognized certain extraordinary features of the skull — its relatively erect poise, small canine teeth and endocranial capacity, scarcely differing from those of extant apes. But he noted also that the form of the brain was human-like in its parietal lobe. In particular, he recognized the impression of what he took to be the lunate sulcus. It was well back, as in modern man, and not well forward as in modern apes. He then made a great intellectual leap: he interpreted this curious blend of traits as evidence for the former presence in Africa of an anthropoid that had moved substantially in a human direction. This he claimed in his historic paper in *Nature* on 7 February 1925. He named the species *Australopithecus africanus*.

Associated Press/Univ. Witwatersrand

Dart — effected a revolution in knowledge.

Many deterrents to the acceptance of Dart's claim were predicated on the accepted wisdom of the day: the idea that Asia, not Africa, had cradled mankind; and the notion that the brain had expanded early in hominization, a view supported by the features of the ill-famed Piltdown bones. Moreover, the Taung specimen was of a child and, it was averred, the nature of the adult could not have been predicted. Arthur Keith, with most later investigators, rejected the evidence of the lunate sulcus, holding that its position could not be identified with certainty on the Taung endocast.

The main controversy Dart stirred up did not abate for 25 years, when many new specimens from the Transvaal were compared with the skeletons of modern apes. It was realized that, even if one discounts the lunate sulcus, enough other features mark the specimen not only as unique, but as morphologically intermediate in several respects between apes and men. Only then did it emerge that Dart's claim had been basically correct and, indeed, that there was every justification for classifying the fossils as members of the Hominidae.

Dart's recognition and interpretation of the significance of *Australopithecus* remains one of the great steps forward in the history of palaeoanthropology. With hindsight, the essence of his 1925 contribution lay in his willingness to overlook the small brain size of *Australopithecus*, in the face of other strong pointers to its evolutionary status. Brain-size alone, he declared in a 1956 paper, was not the acid test; the form of the brain was more important. Late in life, Keith, the first of Dart's main opponents, generously acknowledged that he had been wrong and Dart right: he proposed to call the australopithecines 'Dartians'.

After World War II, following discoveries of fossil baboons at Makapansgat, northern Transvaal, Dart was lured back into the field — and a new chapter opened. Intrigued by the thousands of fossilized, broken antelope bones in that cave deposit, he proposed in 1955 that the bones had been broken deliberately, fashioned and used by the australopithecines. His proposed Osteodontokeratic culture was based on the use as implements of bones, teeth and horncores, especially of ungulates. This notion has now been largely rejected, as evidence has built up that big cats, hyenas and porcupines were probably the bone breakers and accumulators.

But Dart's hypothesis had a remarkable spin-off. When he first proposed his bone-tool theory in 1955, scarcely anything was known of how animals, or agents like sunlight and water, affected bones after death. To disprove Dart's proposal, a host of new studies were made of the effects of such biotic and physical agencies on bones. A new scientific discipline came into being, called taphonomy. Dart's ideas were a major catalyst in the birth of this new field. Thus, it can be claimed of Dart that he effected a revolution in knowledge about man's place in nature, and that indirectly he triggered the foundation of a new scientific discipline.

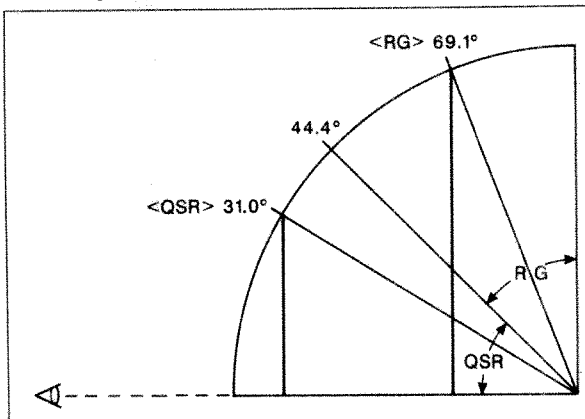
Raymond Dart was born during the flood that swept Queensland, Australia, in 1893. He read science at the new University of Queensland, Brisbane, and medicine at Sydney. After serving in the Australian Army Medical Corps, he worked under Elliot Smith in the Anatomy Department at University College, London. There followed six months as a Rockefeller fellow in the United States. In 1923, be became head of the Department of Anatomy at the newly formed University of the Witwatersrand Medical School, a position he held for 36 years. Dart was a prime architect of the Medical School and a maker of men. The Raymond Dart Collection of Human Skeletons is one of the tangible monuments to his initiative and foresight. Phillip V. Tobias

Phillip V. Tobias is Professor of Anatomy and Human Biology at the University of Witwatersrand Medical School, Parktown 2193, South Africa.

Active galactic nuclei

Pointing towards the source?

Virginia Trimble



QUASARS, like beauty, may be in the eye of the beholder. So suggests Peter D. Barthel in a paper in the latest *Astrophysical Journal*[1] that collates observations collected by his[2] and many other groups of astronomers. According to his version of the unified scheme for active galactic nuclei, radio-emitting quasistellar objects (QSOs) and powerful radio galaxies are the same sorts of objects, seen from different directions, and radio-quiet QSOs may be the similarly oriented subset of powerful galaxies with bright infrared sources (called IRAS galaxies after the satellite that measured their fluxes).

The generic name, active galactic nuclei (AGNs), indicates a long-standing recognition of some kind of unity within the zoo. The beasts on display include (a) quasars (an attempt at pronouncing the acronym QSRS for quasi-stellar radio source), which are optically compact, show broad emission lines at large redshifts, and emit powerfully at radio wavelengths, (b) QSOs (much more numerous and not strong radio sources, but otherwise similar), (c) BL Lac objects (with rapid variability, strong polarization, and weak or no emission lines; named for their prototype), (d) radio galaxies, (e) optically violent variables (OVVs) and (f) Seyfert galaxies (bright nuclei and strong emission lines with moderate redshifts, named for their discoverer). The host galaxies are generally thought to resemble ellipticals for types (a) and (d), spirals for (b) and (f). Many are interacting galaxies.

All AGNs exhibit the astrophysical difficulty of producing lots of energy from small volumes with the capacity for very rapid change in both brightness and location of the emitting regions. And all are currently explained by a standard model[3,4]. Its components are a massive black hole (10^{5-10} times the mass of our Sun) at the centre of a galaxy; energy generation and transport by some combination of gas flowing inward and magnetic fields linking the hole to more distant gas; and one or two outgoing, well-collimated jets of particles, field and photons moving at speeds close enough to the speed of light that special relativity must be applied rather carefully to avoid inconsistencies in interpreting the observations[5].

The model clearly provides a wealth of parameters that can be varied among assorted kinds of AGNs — the mass of the black hole, the rate of gas inflow (relative to an upper limit set by radiation pressure), the field strength and configuration, the geometry of surrounding gas, the mechanism and precision of jet collimation, the dominant components of the jet (plasma of electrons and positrons or electrons and protons; magnetic field; photons), and the angle the jets make with our line of sight.

Earlier versions of a unified scheme[6-9] attached considerable importance to the last, orientation, parameter. A jet seen more or less end-on was invoked to explain several phenomena that are common, but by no means universal, in quasars, including rapid flux variability and rapid outward motion of radio-emitting blobs along the jet direction (called superluminal motion because a naive analysis of it that neglects the effects of orientation and special relativity leads to apparent motion at velocity = 2–10 c). Such a picture successfully organizes a variety of observed features of quasars and their ilk.

Orientation of the approaching jet of active galactic nuclei relative to the observer's line of sight. The dividing line between quasi-stellars and radio and infrared galaxies occurs at about 44°. Thus the average radio galaxy ⟨RG⟩ at 69° should have an apparent, projected radio diameter about twice that of the average quasar ⟨QSR⟩ at 31° as seems to be the case. (Courtesy of P. D. Barthel.)

The classification of some quasars as roughly end-on jets and some as roughly side-on, runs into a couple of difficulties, however. First, presence of superluminal motion should be correlated with small angular size of extended radio emission as projected on the sky. It is not. The paper by Barthel *et al.*[2] in fact reports apparent expansion at 2.5 c for the core of the quasar 4C 34.47, which has the largest projected size of any known (560 kiloparsecs assuming a Hubble parameter H = 100 km s^{-1} Mpc^{-1}). Second, the radio flux we see should be enhanced by beaming and the X-ray flux should not; yet the two are rather well correlated. It is also sometimes hard to understand the non-detection of the expected, diametrically opposed, jet aimed away from us.

In Barthel's restructured scheme (see figure), all quasars are beamed within 44° at us (average, 31°), and the otherwise-directed objects are seen as powerful radio galaxies, whose projected sizes are indeed larger by about a factor of two. Radio-quiet quasistellar objects may be the corresponding end-on views of galaxies that we otherwise see as strong infrared sources (because dust absorbs and re-radiates much of the emission in the equatorial direction). The presence or absence of radio emission is then an intrinsic property of a particular hole–accretion–collimation combination, and X-ray emission must be somewhat enhanced by beaming effects. The Seyfert galaxies provide some supporting evidence. The two subtypes, Seyfert 1 and Seyfert 2 galaxies, have been attributed to pole-on and equator-on directions of view on the basis of other evidence[10]. And, indeed, Seyfert 1 galaxies are more often the strong X-ray emitters; and the most pronounced superluminal galactic source, 3C 120, resides in a Seyfert 1. Barthel suggests that all host galaxies will be found to be experiencing some degree of interaction with neighbours. The relationship with yet another kind of activity, also widely blamed on interactions and called star bursts (meaning bursts of rapid star formation), remains to be worked out.

Barthel provides eight additional predictions of his scenario, pertaining to polarization, optical emission line, counter-jet and infrared properties of the several classes of objects. He also proposes two kinds of observations that could rule it out — evidence for systematic differences in the morphology or in the environments between the host galaxies of quasars and radio galaxies, or between QSOs and infrared galaxies. Curiously, the definitive test of going around to the other side of a few and looking is not mentioned. □

Dating techniques

History revealed from bones

R.E.M. Hedges

As Mark Antony pointed out[1], most of what we should like to know about our forebears lies interred with their bones. But it is no easy task to reconstruct the cultural life of our ancestors from the fragmented evidence that their bones (and other remains) provide. Bones are very complex structures and contain potentially a wealth of information about, for example, an individual's genetic constitution, medical history, environmental influences and cultural practices. They are also far from chemical equilibrium, and information is inevitably lost with the passage of time. The effect of the burial environment, in terms of diagenetic changes both to the organic and inorganic components of bone, is even more marked, the remaining information being overwritten and further scrambled. Nevertheless, progress continues in sifting out the effects of environmental contamination and in deciphering what remains. Some new papers in *Geochimica Cosmochimica Acta*[2-4] exemplify this, and reinforce research reported at a recent workshop[5].

Analytical work on ancient bone ranges from isotope studies to immunochemical detection of antigens, taking in trace-element measurements, amino-acid racemization, protein identification and the search for DNA. So far, isotope methods promise the most straightforward results. These include dating (^{14}C and, much more arguably, $^{230}Th/^{234}U$), and dietary information (^{13}C and ^{15}N). But even here the state of preservation of the bone is paramount.

Radiocarbon dating of bone, especially in the critical period of the transition of man from Neanderthal to modern, thought to have ended about 30,000 years ago, can produce dates far too young because of a small admixture from younger environmental contamination. How this admixture might be separated depends on our understanding of the way in which unknown contaminant molecules can crosslink to degraded bone collagen. The same problems apply to stable isotope results; as carbon and nitrogen atoms pass along the varied food chains of man's diet, the different small degrees of isotope fractionation can be recognized. Distinctions between marine and terrestrial animals, leguminous and non-leguminous plants, as well as plants growing by different photosynthetic pathways, are easily made, and more subtle influences of environment (such as climatic stress or the effect of famine) are now being explored. But the measurements are subject to the relatively inscrutable effects of bone diagenesis.

In something of a technical *tour de force*, Stafford *et al.*[4] have now isolated individual amino acids from bones in varying states of decay and have measured their radiocarbon age by accelerator mass spectrometry. As expected, the results are complicated, but the admixture of environmental amino acids can now be clearly followed. In a mammoth bone known to be about 11,000 years old, the dates obtained for some of the amino acids were only 3,000–4,000 years old.

The new work of De Niro and Weiner[2,3] aims to develop strategies to recover collagen fragments free from contamination. One approach is to exploit subtleties in the biomineralization of the hydroxyapatite/collagen matrix of the bone, in which a small fraction is in the form of multicrystalline arrays. This fraction is preserved after the treatment of the matrix with sodium hypochlorite, and in fossil bone still retains isotope signatures much closer to those expected for the original bone. Non-collagenous proteins and lipids are also apparently better preserved in these 'aggregates'.

A second approach that is being explored is to take advantage of the characteristic sequential structure in collagen: glycine–Y–X, where Y is often proline or hydroxyproline and X is any residue. This structure is specifically cleaved by the enzyme collagenase into fragments of relative molecular mass typically 500–700, which can then be extracted and purified. Although yet to be proved, the benefits for the radiocarbon dating of bone, particularly from hotter regions than northern Europe, are potentially very significant. Much Middle Eastern chronology, for example, rests on dating of unsatisfactory charcoal samples; the collagen levels surviving in bone are usually too low to provide reliable dates by existing techniques. Reliable dates obtained by these new techniques could transform our understanding of some of the archaeology of the region.

Other dating methods are less likely to evade the effects of environmental influence[5]. Uranium-series dating, for example, depends on modelling the uptake of uranium ions by buried bone from the ground water. Even the basic question of why some bones seem better preserved than others found in the same stratum on a site is not yet easy to answer. Perhaps the first steps are being taken in the continuing study of the disintegration of macromolecules from naturally weathering bones in the Amboseli National Park of East Africa. The first few years of a bone's death may be crucial for preserving its information for posterity. □

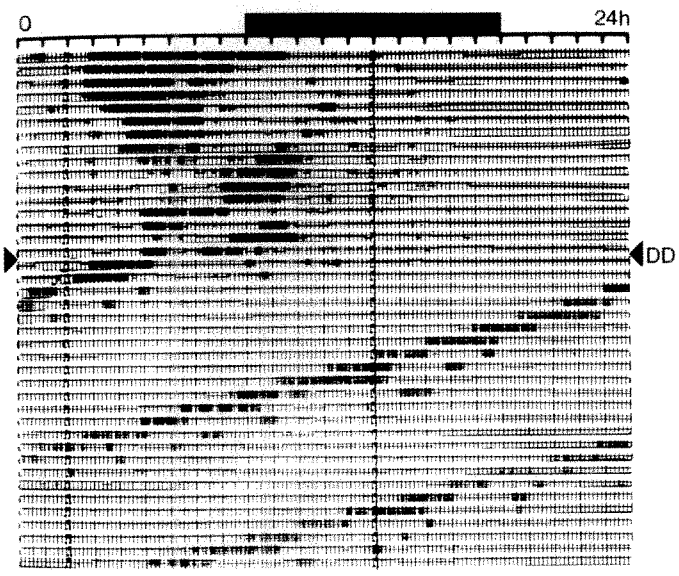
Circadian rhythms

Mutant hamster in a hurry



N. Mrosovsky

THE golden hamster (*Mesocricetus auratus*) is to chronobiologists what the fruitfly is to geneticists. Hamsters occupy this niche because their circadian rhythms of wheel-running activity are easy to measure, easy to quantify and highly predictable. At a recent meeting*, Martin Ralph (previously at the University of Oregon, now at the University of Virginia) reported his new work[1] on how the circadian-activity rhythms of hamsters can be experimentally manipulated by transplanting a part of the brain.

When the light–dark (LD) cycle is 14–10 hours, wheel-running in this nocturnal species is neatly confined to the hours of darkness. An occasional individual displays a sloppy or unusual rhythm, and such animals are usually discarded from experiments. But when Ralph noticed that one hamster started to run in its wheel several hours before the onset of darkness in a 14–10-hour LD cycle (see figure), he placed the animal in constant darkness, reasoning that the early activity onset in the presence of a LD cycle might reflect a circadian pacemaker with an unusually fast frequency. In this condition the hamster's activity free-ran with a periodicity of only 22 hours. The shortest free-running rhythm previously recorded[2] by Ralph and Menaker, out of more than 1,000 hamsters tested, was 23.5 hours.

Tests on these offspring revealed that there is a trait, an abnormally short free-running circadian period (*tau*), at a single autosomal location[2]. The *tau* mutant can thus be used to tackle unresolved questions about biological rhythms. For example, it is thought that the supra-

Raw data showing the discovery of the mutant *tau* hamster. Each line represents 24 hours. Successive days are mounted beneath each other. Dark pen marks indicate periods of wheel-running activity; dark bar at top, time of darkness on a light–dark 14–10-hour schedule; arrows, change of lighting schedule from light–dark 14–10-hour to continuous darkness (DD). (Courtesy of M. Ralph.)

chiasmatic nuclei (SCN) in the brain are the site of circadian pacemakers in mammals, but this assertion has not been proved. True, lesions in this area abolish circadian rhythms of activity and other variables[3], but this does not prove that a pacemaker resides there. It could simply mean that the integrity of this area is necessary for the expression of rhythmicity. Transplanting fetal SCN into animals whose own SCN have been ablated can result in restoration of rhythms. This again does not prove that the SCN contain a pacemaker. The circadian machinery might be elsewhere, with the SCN simply providing some input necessary for its functioning. What is required is a demonstration that transplants produce rhythms that have characteristics which are specific to the clock of the donor.

In sparrows, removal of the pineal results in a loss of circadian rhythmicity. Menaker and his co-workers have previously shown that transplants of the pineal gland restore rhythmicity to pinealectomized sparrows, but also that the phase of the donor's rhythm determines the phase of the recipient's rhythm[4]. Thus, the time of day at which the recipient sparrows become active depends on whether the donor birds have been kept on a normal or a reversed LD cycle. This still is not quite definitive because the phase of a rhythm is a temporary characteristic that can be quickly shifted in various ways. It would be more convincing to transplant a persisting stable characteristic of a clock such as the speed with which it runs. In sparrows, however, there is too little inter-individual variation and too much intra-individual variation to make transplanting periodicity convincing.

There have been some attempts to transplant periodicity between strains of rats with different clock speeds, but activity rhythms in rats are generally not as clear as those in hamsters. A hamster mutant with a period outside the range of those for the wild-type is the ideal subject for this kind of work.

Ralph's new data show that the period of the circadian-activity rhythms of wild-type hamsters can be shortened first by ablating their own SCN and then by inserting fetal mutant SCN. Conversely, the period of mutant hamsters can be lengthened by replacing their own SCN with fetal wild-type SCN. This result is the confirmation of the pacemaker role played by the SCN. It is also a striking example of the transplantation of a behaviour.

The mutant (*tau*) hamster is likely also to provide insight into other questions about biological rhythms. Attempts to discover the gene product of this single locus and to unravel its molecular biology have already begun. It will be interesting to make comparisons with the fruitfly period (*per*) gene, which has already been cloned and sequenced (see the recent discussion in News and Views[5]). Understanding fundamentals about rhythmicity will eventually help in ameliorating rhythm disturbances such as those occurring in jet lag, shift work and some types of affective disorder. A nice touch is that Ralph and Menaker have rejected the option of trying to patent the mutant hamster. Altogether, this is textbook science at its best. □

Daedalus

A reducing diet

COOKING is not a consciously chemical discipline. Only by trial and error have chefs learnt to exploit the hydrolysis and denaturing of proteins, the partial oxidation of fats, and the Maillard reaction between proteins and sugars, to produce their wide palette of sumptuous and tempting flavours. It is largely oxygen that develops the subtleties of taste, by forming the delicate traces of higher aldehydes, ketones and esters that impart flavour; but over-oxidation gives sour, acrid fatty acids. So cooking limits oxidation: typically by careful temperature control, or (as in frying and boiling) by submersion.

Modern industrial food processing uses anti-oxidant additives; but Daedalus has a more wholesome approach. The traditional chef has to join his battle with oxygen over an open stove, and faces rancid, burnt or over-cooked disaster if he loses it. But modern electric and microwave ovens are quite independent of air. So DREADCO's chefs are cooking all sorts of dishes not in air, but in a non-oxidizing atmosphere of nitrogen or argon.

This new sort of cooking has many benefits. Very high temperatures can be explored under full control: the food cannot burst into flame. Controlled amounts of oxygen can be introduced at crucial stages, to promote the development of new and subtle flavours without going too far: just as wine develops its subtle bouquet from the slight leakage of oxygen into the bottle through the cork, but is spoiled if too much gets in. Gourmets should revel in the new and unexpected flavours that will thus be teased out of quite ordinary foodstuffs. Dull and obvious products like lentils and rhubarb and corned beef may come alive with subtle delights; hidden virtues may be revealed in marrow, tapioca, and the British sausage; the range of delightful complementary pairs, like eggs and bacon, and fish and chips, may be wonderfully extended. Culinary anaesthetics like salty gravy and sugary custard may no longer be needed. Even hopeless raw materials like lettuce and battery chicken may at last be made to taste of something.

More boldly still, the DREADCO chefs are filling their new ovens with frankly reducing atmospheres: hydrogen, carbon monoxide, even ammonia. The entirely novel flavours thus developed may be so strange and amazing as to be positively overwhelming. The hydrogen-reduction oven may be best employed as a 'decooker' to rescue overdone cooking. By converting the sour fatty acids of over-oxidation back to flavoursome aldehydes again, an over-cooked joint, deadburnt cake or pyrolysed pie might be reclaimed for the gourmet's table.

David Jones

Safety of Cameroonian lakes

SIR—In dealing with lethal releases of CO_2 from lakes, the people of Cameroon require firm scientific evidence on which to base decisions for evacuation and disaster control. We are concerned, therefore, by the misleading and speculative letter by Pourchet *et al.*[1] stating "it is likely that many of the crater lakes (in Cameroon) have emitted gas bursts, or will do so". Our recently completed studies suggest that gas bursts from other lakes in Cameroon are, in fact, unlikely.

The accumulation and massive release of CO_2 gas from crater lakes is unique, and has been documented only for lakes Nyos and Monoun in Cameroon[2,3]. The circumstances required for this phenomenon to occur are very rare. There must be an adequate gas supply, such as the CO_2-charged soda springs occurring in Cameroon, and this supply must be trapped by surface deposits or by a deep, strongly stratified lake. There is also good evidence that a build-up of CO_2 and solutes in bottom waters occurs long before any gas burst[2,4]. Our recent limnological survey indicates no such premonitory build-up in any Cameroonian crater lake apart from Nyos and Monoun[4,5].

The argument of Pourchet *et al.* seems to rest on two points. The first is that porewaters and bottom waters of Lake Bambuluwe are "close to gas saturation at the sampling depth (58 m)". But observing gas bubbles in a core brought to the surface, as they did, indicates little more than oversaturation at pressures (below 5.8 atmospheres) greatly reduced from those found in the bottom sediments. Such gas pressures are common in freshwater sediments; indeed nearly all of the sediment cores we have raised from 11 different crater lakes in Cameroon degassed at lake surface pressures.

The second part of their argument links the homogeneous distributions and higher than expected concentrations of ^{210}Pb in sediment cores from lakes Nyos and Bambuluwe. Our sediment cores from lakes Nyos and Monoun were mixed rapidly because of violent degassing at the surface. Pourchet *et al.* do not detail their methods, but only *in situ* sampling or freeze-coring would maintain stratigraphic integrity of the sediment in a gas-charged lake. In Lake Bambuluwe, the uniformly high ^{210}Pb concentrations they report for the upper 15 cm have other explanations. For example, a 1m core taken by us in 1985 revealed an upper 15–20-cm layer of clastic material overlying darker micaceous mud. This surface layer may correspond to the recently built access road around the lake. Such watershed disturbances are known to increase the flux of radiogenic lead to lakes[6]. We believe that the reported similarities between sediment ^{210}Pb in Lake Nyos and Lake Bambuluwe may be spurious, and thus inappropriate for use as predictors of future gas bursts.

Dominance of South American marsupials

SIR—The discovery of mammal remains from the early Cretaceous of Cameroon by Jacobs *et al.*[1] is of unquestioned importance in interpreting mammalian evolution and biogeography, particularly regarding the key transitions to metatherian and therian 'grades'. The statement by Jacobs *et al.* that metatherian marsupials represent "the dominant living mammals of South America and Australia", is surely coloured by a geological perspective, however.

Although the ecological and evolutionary dominance of Australian marsupials during the Tertiary and Quaternary seems well founded, this is not true of today's American marsupials, despite their remarkable diversity and radiations in the Tertiary[2,3]. Modern New World marsupials comprise only three families, 15 to 19 genera, and 85 species, most endemic to tropical South America[4]. At one comparatively well-studied site in south-eastern Peru (Cocha Cashu in Manu National Park), nine species of marsupials comprise 9 per cent of the known mammal fauna — there, four mammalian orders (Rodentia, Chiroptera, Carnivora and Primates) exceed the familial, generic and specific diversities of marsupials, and Manu records of bats and rodents are incomplete[5]. Elsewhere, 34 genera and 49 species of bats have been recorded at a single locality in Rondônia, western Brazil (specimens in the Museu de Zoologia, Univ. São Pauolo), and that country supports at least 7 families, 53 genera and 183 nominal species of rodents[6].

Although 12 mammalian orders occur in South America, 43 per cent of its mammal species are rodents, including at least 250 species of Sigmodontinae (Muridae)[7]. In terms of diversity and abundance, rodents and bats greatly outstrip marsupials as the most dominant orders of modern South American mammals. Indeed, the contrast in diversity and dominance of marsupial lineages before and after the "Great American Interchange" has been an important focus for studies of faunal dynamics and turnover.

Black holes dispute

SIR—Gunzig, Géhéniau and Prigogine[1] attempted a numerical evaluation of the inflationary model of black hole production postulated[2] some time ago. Unfortunately, their paper contains several errors. We emphasize that the principal hypothesis[2] is not destroyed as several modifications to the model of Gunzig *et al.* are not only possible, but likely.

First, the matching conditions of equations (14) and (15) of Gunzig *et al.* are stated to imply $\alpha \simeq \sqrt{\beta}$. In fact these conditions are not sufficient and the value of α is very sensitive to the input. Thus, for example, as β / C^2 varies from $(1 - \varepsilon)$ to $(1 + \varepsilon)$, where $\varepsilon \equiv 1 - \Delta_i \simeq 10^{-27}$, α varies from 0 to $\sqrt{\beta}$. Input must be fine-tuned to 27 decimal places to obtain the result of Gunzig *et al.*. It is equivalent to tuning a discontinuity in temperature between de Sitter and Robertson–Walker stages to the same precision.

Second, Gunzig *et al.* compute t_e using three helicity states. The present count, a lower bound, is 119. Using the model of Casher and Englert[2] to determine the de Sitter temperature (as we consider the determination of Gunzig *et al.* unreliable) the matching radius is reduced by a factor of 10^{-23}. But the hypothesis is not destroyed because the true turnover time is expected to be much greater than t_e.

Third, Gunzig *et al.* determine the mass density of the massy component of matter from the matching condition. To obtain the number density and thence the entropy per proton they divide this by the proton mass. But the matching temperature is $\sim 10^{17}\, m_{proton}$. So the protons (which are certainly in equilibrium) will be in the β/R^4 term of the energy source and not

in the α/R^3 term as Gunzig *et al.* suppose. Their calculation could be used to estimate the lepto-quark density of grand unified theories, but certainly not the density of any of the present constituents of matter.

We stress that the field-theoretical foundations of the production mechanism as well as the instability of Minkowski space are flimsy, at best — though not necessarily wrong — owing to the use of an unconventional and arbitrary subtraction procedure[2]. The model of inflation through black hole production[2] must be regarded as a hypothesis without solid theoretical support. If such exists, it must await the yet-to-come quantum theory of gravity. To our mind, any numerical evaluation, unless it definitely detroys the model, is premature. (A more detailed account of our calculations is available in ref. 3 or from us).

R. BROUT
PH. SPINDEL
Service de Physique Theorique,
Université Libre de Bruxelles,
Plaine Campus (C.P. 225),
B–1050 Bruxelles, Belgium

GUNZIG REPLIES—Brout and Spindel claim that our paper[1] contains several "errors". We firmly disagree with this conclusion. I will consider their criticisms.

The first point concerns the matching parameters α and β. We agree entirely with their remark concerning the sensitivity of α to the input. But they miss the key point, which is that there is a subtle compensation of infinitesimals which leads to our result $\alpha/\sqrt{\beta} = 0(1)$: it appears indeed that the solution of the matching equations (14) and (15) is given by $\alpha/\sqrt{\beta} = 1-\varepsilon/\varepsilon_1$, where $\varepsilon = (\beta/C^2)-1$ and $\varepsilon_1 = 1-\Delta_1 \approx 10^{-27}$. It results straightforwardly from the definitions of the parameters β and C, that $\beta/C^2 = 1/\Delta_1\ (T/T_{BH})^4$. The value of T/T_{BH} is easily evaluated in the euclidean parameterization of the joining conditions; the latter is appropriate as the joining point belongs to the de Sitter asymptotic region. It appears that $(T/T_{BH})^4 = 1-\varepsilon_2$ with $\varepsilon_2/\varepsilon_1 = 0(1)$. Hence,

$$\alpha/\sqrt{\beta} = [1-\frac{(\varepsilon_1-\varepsilon_2)}{\varepsilon_1}] = \frac{\varepsilon_2}{\varepsilon_1} = 0(1)$$

as we announced[1]. Moreover, when the cosmogenesis model is wholly reformulated in the framework of euclidean Robertson–Walker parameterization, as we did recently[4], the matching conditions give rise to much simpler algebraic relations than those associated with the open Robertson–Walker parameterization. These relations lead straightforwardly to conclusions identical to those resulting from the $\approx \sqrt{\beta}$ open condition.

The second point concerns the number of helicity states involved in our considerations. We mentioned this problem at the time[1]. Since then, we have shown[4] that the inclusion of any higher number of helicity states leaves all the results unaltered, provided that the black hole mass M is increased (by a factor of about 5 for $N = 100$, for example).

The third criticism concerns the use of the proton mass in the evaluation of the specific entropy. First of all, as mentioned in our paper[1], the fundamental quantity to be considered is the adiabatic invariant $(1/T)\ (\varrho_\gamma/\varrho_m)$ which does not involve any elementary particle mass at all. Our calculations produce the correct experimental value for this quantity as well. Nevertheless, the quantity which is traditionally discussed in the literature is the specific entropy per proton. To obtain the latter, it is fully legitimate in our context to use the proton mass. Indeed our joining procedure connects directly the de Sitter stage to the present cosmological stage. We mentioned in our conclusions that in a more realistic model, our parameters α and β would be time-dependent.

In addition to these three specific criticisms, Brout and Spindel are pessimistic about the field-theoretical foundations of the production mechanism as well as the instability of Minkowski space. These remarks are directed towards the series of papers on the subject, initiated by Brout, Englert and myself[5]. I share this concern. It is for this very reason that we have now developed[4] a phenomenological approach which eliminates the field theoretical subtleties. In this context, simple thermodynamical arguments render the explicit use of field-theoretical considerations no longer necessary.

In conclusion, Brout and Spindel have missed the main points of our paper. These involve the reinterpretation of Einstein's equations leading to a burst of entropy associated with matter creation in the early stages of the Universe.

Selective action of artificial membranes

SIR—Rubinstein *et al.*[1] claim to have prepared the first example of a stable, ion-selective artificial membrane of monolayer thickness, which successfully mimics basic structural and functional properties of natural bilayer membranes. Their membrane was prepared on a gold electrode by coadsorption of two components from bicyclohexyl/chloroform solution. After transfer to an aqueous solution, the first of these (OM) apparently acted as a blocking agent, and the second (TBEA) as an 'active' ligand forming 1:1 complexes with divalent metal ions, such as Cu^{2+}, but not with travalent ions, such as Fe^{3+}.

To establish that their 'artificial membrane' was working as they claimed, the authors needed to prove that the only observed electrochemical reaction was caused by the active ligand chemically distinguishing between Cu^{2+} and Fe^{3+} ions in solution. Although certain evidence was adduced in favour of this hypothesis, we believe that there is an alternative and much simpler interpretation of the experimental results in which the active ligand has no role.

When the 'artificial membrane' was placed in a solution of Cu^{2+} and Fe^{3+} ions, Rubinstein *et al.* observed no Cu^{2+} 'underpotential' (non-bulk) and Fe^{2+}/Fe^{3+} peaks; repression of the peak for bulk deposition of copper onto the electrode by ~ 250 mV; and a loop in the cyclic voltammetry. Rubinstein *et al.* interpret these observations as follows: Cu^{2+} peaks were absent because copper atoms were deposited inside the 'artificial membrane' at some distance from, rather than directly on, the electrode surface; the lack of Fe^{2+}/Fe^{3+} peaks was due to a lack of sites where Fe^{3+} ions could bind; and the shift in the bulk copper peak and the existence of the voltammetric loop were evidence of a "preferred perpendicular orientation of the ligand". Furthermore, they invoke quantum-mechanical tunnelling barrier to explain the shift of the copper deposition peak, and suggest a type of autocatalysis to explain the voltammetric loop.

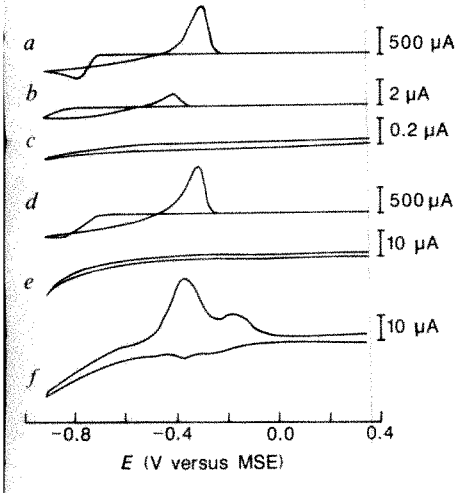
But all the above evidence is also consistent with a simple physical model in which Cu^{2+} ions are discharged directly onto the surface of the gold electrode. The electrode may be imagined as being, say, only 99.9% covered by the monolayer and not 100% as claimed. Such a coverage would be sufficient to eliminate all but 0.1% of both the copper 'underpotential' and Fe^{2+}/Fe^{3+} peaks, making them undetectable on the scale used, but would leave enough area of uncovered gold to allow the nucleation and growth of bulk copper crystals. Moreover, the high coverage would also block a large fraction of the active sites for nucleation on the gold surface, so that the nucleation overpotential for copper deposition would be increased by several hundred millivolts, precisely as observed. The loops in the voltammograms are no more than the expected response of a nucleation-and-growth process to a triangular scan of applied potential, as proved elsewhere[2].

STEPHEN FLETCHER
CSIRO Division of Mineral Products,
PO Box 124, Port Melbourne,
Victoria 3207, Australia

RUBINSTEIN *ET AL.* REPLY—Fletcher challenges our main conclusion, that the selective response of the gold electrode/(TBEA+blocking component) system to Cu^{2+} ions in the presence of, for example, Fe^{3+} is due to selective complexation of Cu^{2+} ions by TBEA molecules, and suggests an alternative interpretation. But experimental evidence[1] and other data clearly support our selective complexation model and exclude Fletcher's suggestion.

Selective behaviour of the same kind as we reported is observed when TBEA is replaced with TBPA or when the blocking agent OM is replaced with naphthol polymer (NP) (Fig. 2 in ref. 1) or polymerizable octadecyl trichlorosilane (OTS)[3,4] (*a* in the figure). As we have shown previously[3,4], diffusion-controlled faradaic currents are generally enhanced at randomly distributed pinholes. A situation in which the bulk-copper peaks are prominent whereas copper 'under potential' and Fe^{3+}/Fe^{2+} peaks are totally absent would therefore require rather unusual size and spatial distributions of pinholes. It is unlikely that three different blocking elements and two different ligands lead to the same special kind of pinhole distribution. Moreover, being deposited electrochemically, NP should block all uncoated electrochemically accessible sites. An NP layer of comparable thickness on a bare gold surface indeed blocks copper deposition completely[1].

Ionic competition experiments provide strong experimental support for the selective complexation model. Zn^{2+} and Cu^{2+} ions, which resemble Cu^{2+} in coordination requirements, successfully replace Cu^{2+} at monolayer ligand sites although being electrochemically inactive under the present conditions. The Cu^{2+} peaks are suppressed in the presence of Zn^{2+} (*a–c* in the figure), and at a high Zn^{2+} concentration (~ 8.0 mM) the Cu^{2+} peaks cannot be detected at all. The same is observed with Cu^{2+} (in both cases the peaks are fully recovered in pure Cu^{2+} solution). Conversely, the presence of non-complexing ions, such as Fe^{3+} or Ce^{3+}, has essentially no effect on copper deposition (Fig. 2 of ref. 1; *d* in the figure). These results are consistent with complexation selectivity, but not with reaction at uncoated areas. Moreover, the complete disappearance of Cu^{2+} peaks in these competition experiments indicates the absence of electrochemically active pinholes down to <0.005% of the total area.



Fletcher suggests that the active element (TBEA or TBPA) plays no role in the observed selectivity. Figure 1*e* and *f* shows control experiments with pure OM monolayers on gold, in which a small number of pinholes were deliberately introduced (manuscript in preparation). At ~ 99.9% electrode coverage[4], Fe^{3+}/Fe^{2+} peaks indeed disappear whereas Cu^{2+} peaks still persist. However, these peaks (< 4% of the intensity observed with gold/(TBEA+OM or OTS)) clearly indicate normal copper deposition on bare gold (Fig. 2*a* of ref. 1), in that they show prominent copper 'underpotential' features and no unusual overpotential for bulk copper nucleation (as Fletcher suggests will be the case for pinholes). The presence of Zn^{2+} in solution here has, as expected, no effect on copper deposition. Thus, the characteristic features of Cu^{2+} reduction cannot be observed in the absence of the active component.

Fletcher's suggestion of a nucleation overpotential rather than a tunnelling barrier does not contradict our basic model. The overpotential and voltammetric loop, indicative of a barrier to electron transfer which diminishes as metal deposition starts, can be caused by either or both of these phenomena; its precise nature has no bearing on our principal conclusions. We suggested the tunnelling barrier as a possibility based on the observation of an increased barrier when using TBPA in place of TBEA, and consequently an increased Cu^{2+}-to-electrode distance. The thickness of a TBEA monolayer — 9.5±1.0 Å as measured by ellipsometry — supports the assumed perpendicular orientation of the ligand molecules, and thus the assumed distance of complexed Cu^{2+} from the electrode. Furthermore, the overpotential and loop cannot be reproduced in the absence of TBEA or TBPA.

Rapid reversibility of lake acidification?

SIR—Battarbee *et al.* recently claimed[1] that diatom cores showed "a trend towards progressively decreasing acidity" in two Scottish lochs. They put these data forward as evidence for rapid reversibility of acidification in Galloway lochs in response to a decrease in acid deposition, in contrast to model predictions which show a much slower response. Unfortunately, the data do not justify this optimistic conclusion, although they do raise some interesting questions.

Battarbee *et al.*[1] do not present the customary diagram of *p*H change with time on the grounds that the changes observed are within the errors of the model for *p*H reconstruction. The diagram can be constructed (Fig. 1) from measurements on their Fig. 2 (which incidentally contains a mistake: the percentage frequency figures would be multiplied by 2) using the index B method described elsewhere[2]. There is clearly no simple relationship between the inferred *p*H of Loch Enoch and sulphur deposition at Askalemuir nearby[3], or between inferred *p*H and SO_2 emissions in the United Kingdom. A reasonable inference would seem to be that the *p*H of Loch Enoch is not sensitive to short-term (10-yr) changes in sulphur emissions of up to 40%, within the limitations of the diatom core method (±0.3 *p*H units[2]).

To reduce the uncertainty of the diatom methods, Battarbee *et al.* used correspondence analysis, an ordination technique which aims to simplify the structure of multivariate data by projecting it onto several principal axes[4]. The difficulty with such techniques is that the axes have no direct physical integration: this has to be inferred from other evidence. One criterion for a successful ordination is tht replicate samples show the same patterns[4]. The two-dimensional projections of Batterbee *et al.*[1] show similar patterns only in that the general direction for replicate cores in each loch is the same. However, in one loch the time track goes east–west. Recent changes in direction are meant to indicate recovery, but in Loch Enoch the time track which had been proceeding south–east turns west and then north, whereas in Round Loch of Glenhead the 1984 core track describes a little circle and turns north–west, and the 1986 core which was going west–north–west turns south–east.

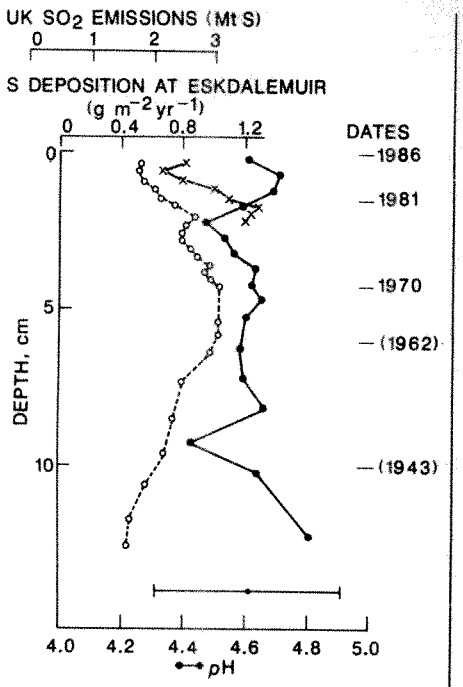

Fig. 1 Inferred *p*H (index B)[2] in Loch Enoch from Fig. 2 of ref. 1 (closed circles). Dates are taken from ref. 1 and, by inference, from the 1982 core (in parentheses). The estimated standard error of the method[2] is shown below. Sulphur deposition at Eskdalemuir[3] 80 km distant (crosses) and UK SO_2 emissions[3] (open circles) are also shown.

It is difficult to see how such diverse behaviour implies acidification followed by recovery, particularly as the three tracks in Fig. 4 of ref. 1 occupy different positions in two-dimensional space.

The chemical evidence presented by Batterbee *et al.*[1] appears more compelling, particularly as the 'non-marine' sulphate has decreased roughly in parallel with deposition, implying that these catchments do not store or release sulphur. However, only two or three samples per year were taken and there have clearly been influences on water chemistry other than sulphur deposition. The 45–60 per cent increase in Cl^- between the 1978 and 1984 samples shows there were one or more sea-salt episodes influencing the chemistry of the later period. The non-marine calcium has doubled in one loch, a result completely at variance with correct understanding of acidification and de-acidification processes[5], which would predict a decrease in Ca^{2+} with reducing SO_4^{2-}. Has there been some increase in calcium input to these catchments or some catchment disturbance (which would also account for the increase in sedimentation rate[1])? I conclude from the paper[1] that diatom-core data have no rapid recovery resulting from reduction in SO_4^{2-} deposition, but that direct chemical data show intriguing patterns for further investigation.

RICHARD SKEFFINGTON
Central Electricity Research Laboratory, Kelvin Avenue, Leatherhead, Surrey KT22 7SE, UK

BATTARBEE *ET AL.* REPLY—Skeffington's attempt to dismiss our evidence for the reversibility of lake acidification seems to be based on a misreading or misunderstanding of our paper[1]. First, we do not argue for a rapid recovery, rather for "little delay ... in the response.... to a decrease in acid deposition". The extent of the recovery is quite minor.

Second, we argue that the sensitivity of diatom–*p*H reconstruction models is too low to be of value in this context where the change is about 0.1–0.2 *p*H units, yet Skeffington presents such a reconstruction.

Third, we argue for floristic reversal as a more sensitive indicator and the ordinations presented clearly show that present diatom assemblages are similar to pre-1970 floras. It is not necessary to show that the axis is a *p*H one as the acidification histories of both these sites are already known[6,7]. To demonstrate this point, we use in Fig. 2 a canonical correspondence analysis[8] of the Loch Enoch data as before, but here constrained by the modern chemistry and diatom assemblages of other Galloway lakes. The first axis is clearly identified as a *p*H-related axis.

Fourth, Skeffington has misread the frequency of chemical sampling. Samples were taken at 2–3-month intervals, not 2–3 times per year.

Fifth, increases in sea-salt inputs reduce the *p*H of surface waters. Therefore, contrary to Skeffington's implied argument that the higher sea-salt concentrations in the 1984–85 data set would reduce the *p*H difference between the sampling periods, the differences would have been greater if the 1978 values had been maintained.

Sixth, it is not relevant to use the usual sea-salt ratios to calculate non-marine calcium because cation exchange processes can also produce elevated calcium levels as well as lower *p*H values in surface waters with sodium being retained on soil-exchange sites[9].

Contrary to Skeffington's view, both the floristic and chemical data presented in our paper[1] can only be interpreted as evidence for reversibility. It would be useful to assess whether similar responses have occurred at other sites with differing catchment characteristics, and to consider the extent to which reversals can be sustained if sulphate deposition were not further reduced[10].

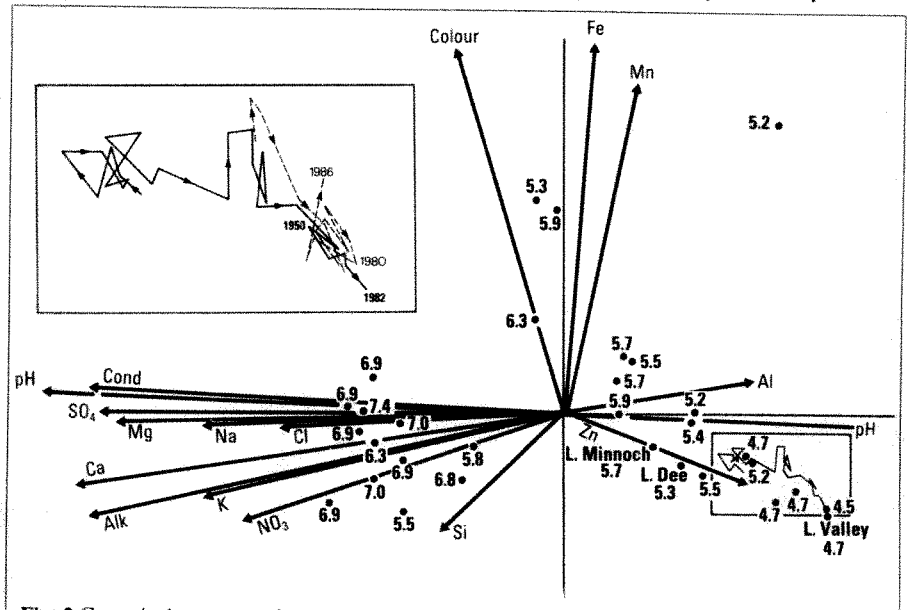

Fig. 2 Canonical correspondence analysis of Galloway lakes showing environmental axes and the *p*H of sites. The time-track for the 1982 Loch Enoch core is also shown. The inset shows an enlargement of this time-track along with the time-track for the 1986 core.

Reader Service No 2

Bringing you the latest findings in DNA mapping and sequencing research and enabling you to publish DNA sequence data papers in full...

SCOPE

The journal will publish:
- mapping data that would be useful to future DNA sequencing
- DNA sequence data in full
- new DNA sequencing procedures and allied techniques
- analyses of DNA sequences
- computer methods to analyse DNA sequences
- compilations of sequence motifs of DNA and proteins
- regular reviews on sequencing especially methodology and the latest techniques

and provide a forum for the exchange of research experience and advice, through a Letters to the Editor section

CALL FOR PAPERS

The Editors welcome original research papers and short communications. The journal will also publish commissioned review articles. Papers and suggestions for reviews may be submitted to the Editor in Chief or to any of the Editors for consideration. There are no page charges to authors or institutions. For further information and Notes for Contributors, please contact the Editors or the Marketing Department at Harwood Academic Publishers.

First issue due Autumn 1989

New volumes from

Handbook of Experimental Pharmacology

Edited by G. V. R. Born, P. Cuatrecasas, H. Herken, A. Schwartz

Volume 84
K. Bartmann, Wuppertal (Ed.)

Antituberculosis Drugs

With contributions by K. Bartmann, H. Iwainsky, H. H. Kleeberg, P. Mišoň, H. A. Offe, H. Otten, D. Tettenborn, L. Trnka

1988. 68 figures. XXIV, 566 pages. Hard cover DM 590,–. Prepublication price Hard cover DM 472,–. ISBN 3-540-18139-3

Volume 84 comprehensively reviews the preclinical evaluation of all 14 antituberculosis drugs which have come into clinical use since antituberculosis chemotherapy began.
The following topics are dealt with exhaustively for each drug: chemical properties, experimental activity in vitro in cells and in animals, type and mechanism of action, experimental pharmacology and toxicology, and pharmacokinetics in animals and man.

Volume 83
P. F. Baker (Ed.)

Calcium in Drug Actions

1988. 123 figures. XXVI, 567 pages.
Hard cover DM 590,–. ISBN 3-540-17411-7

Contents: The Multiple Physiological Roles of Calcium: Possible Sites for Pharmacological Intervention. – Calcium Receptors and Calcium Metabolism. – Calcium and Physiological Function. – Drugs and Toxicological Agents that Either Mimic Calcium or Elements of Intracellular Calcium Metabolism. – Subject Index.

Volume 82
C. Patrono, University of Rome, **B. A. Peskar,** University of Bochum (Eds.)

Radioimmunoassay in Basic and Clinical Pharmacology

1987. 129 figures. XXII, 611 pages.
Hard cover DM 580,–. ISBN 3-540-17413-3

The development, validation and application of radioimmunoassay (RIA) techniques are discussed in this volume. Methodological and conceptual issues related to the main classes of mediators, and to the drugs themselves, are comprehensively covered. Topics often segregated in subspecialty textbooks are here combined in one source of information.

Volume 81
G. R. Strichartz, Boston (Ed.)

Local Anesthetics

1987. 52 figures. XII, 292 pages.
Hard cover DM 280,–. ISBN 3-540-16361-1

Volume 81 gives the most recent view of the classical local anesthetics used clinically to control pain and stabilize cardiac function. The mechanisms of anesthetic action and the basic pharmacological aspects are reviewed. The relationship between local anesthetic structure and activity as assayed at the most sophisticated levels of electrophysiological analysis is uniquely presented.

Reader Service No.1

☐ **ONCOGENE**
AN INTERNATIONAL JOURNAL

Editors: Graham Currie and John Jenkins, Marie Curie Research Institute, Oxted, Surrey, UK

Prem Reddy, The Wistar Institute, Philadelphia, USA

This new journal includes full and detailed papers as well as short communications relevant to all aspects of oncogene research, including the following topics: cellular oncogenes and their mechanisms of activation, structure and functional aspects of their encoded proteins, oncogenes in RNA and DNA tumour viruses, presence of oncogenes in human tumours, relevance and biology, cell cycle control, immortalization, cellular senescence, regulatory genes and "anti-oncogenes", growth factors and receptors.

The international editorial board draws upon a wide range of expertise from the UK, USA, USSR, Federal Republic of Germany, France, Canada and Israel.

☐ **BONE MARROW TRANSPLANTATION**

Editors: John Goldman, MRC Leukaemia Unit, Royal Postgraduate Medical School, Hammersmith Hospital, London, UK

Robert Peter Gale, Division of Hematology and Oncology, UCLA School of Medicine, Los Angeles, USA

A new journal which publishes clinical results in man and experimental results with animals. It covers allografting and autografting, HLA and other methods of selecting donors, graft-versus-host diseases and methods to prevent and treat it, and much more.

☐ **ANTI-CANCER DRUG DESIGN**

Editors: Stephen Neidle, Cancer Research Campaign Biomolecular Structure Unit, Cancer Research Institute, Sutton, Surrey, UK

Stan T. Crooke, Smith Kline and French Laboratories, Philadelphia, USA

Shigeru Tsukagoshi, Cancer Chemotherapy Centre, Japanese Foundation for Cancer Research, Tokyo, Japan.

This journal publishes original research papers, reflecting the increasing importance of the tools of structural and molecular biology as well as more classical methodologies in the development of novel anti-cancer agents.

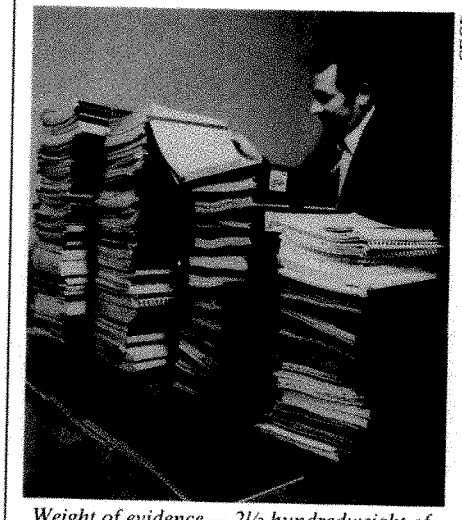
The inquiry inquiry

Wolfgang Rüdig

Sizewell B: An Anatomy of the Inquiry. By Timothy O'Riordan, Ray Kemp and Michael Purdue. *Macmillan, London: 1988. Pp.474. £45.*



EVER since the Windscale inquiry of 1977, the public inquiry has been central to any discussion of the politics of nuclear power in Britain. The 100 days of Windscale made the 'civil' use of nuclear power a prominent issue in British politics, and debate over the virtues and drawbacks of the 'ritual' of nuclear inquiries produced countless articles and books. When in 1980 the government announced its intention to hold a public inquiry into the first pressurized water reactor (PWR) to be built in Britain, the stage was set for further argument about public involvement in reaching decisions about nuclear power.

The inquiry into the PWR project at Sizewell in East Suffolk eventually opened in July 1982. It broke all records in terms of its length and costs, finally being closed in March 1985 after sitting for 340 days. The inspector's report was formally submitted to the responsible minister in December 1986; his consent for the project to go ahead was given in March 1987. Work started in the same month, more than seven years after the respective nuclear-expansion programme had first been announced by the government. But by then, there was no powerful opposition movement making a determined effort to stop it. Although the political fall-out of Chernobyl had swept away most other nuclear development programmes in Western Europe, Britain was able to start a new phase of nuclear expansion without any serious difficulties over legitimation. Any analysis of this situation has to take the Sizewell B inquiry into account.

A team from the University of East Anglia, led by Professor Timothy O'Riordan, was given the task by the Economic and Social Research Council of analysing the inquiry. The results of the project have now been published. Mirroring its subject matter, *Sizewell B: An Anatomy of the Inquiry* can claim to be the longest and costliest book ever written on a British public inquiry. After five years of research, which was completed in May 1987 and has resulted in this well-produced book, we may ask "Was it worth it?". Do we now know more about the Sizewell B inquiry, the reasons for its length and costliness, its result and the political repercussions? Are we now better placed to evaluate the political conflict over nuclear energy and assess the effect of the inquiry on nuclear policy making?

The authors certainly faced a mammoth task in coming to grips with the unprecedented amount of material generated by the inquiry. They help the reader by including a number of appendices providing, *inter alia*, information on the chief parties involved and an indispensable list of acronyms (a total of 159). Armed with such auxiliary implements, one can delve into the maze of 12 chapters, covering a further 413 pages, which examine the inquiry from different angles.

Was it worth it? On the positive side, the description of the events surrounding a number of key issues is a notable

CEGB

Weight of evidence — 2½ hundredweight of it at the Sizewell inquiry from the Central Electricity Generating Board alone.

achievement. The arduous routine of attending endless inquiry sessions and meetings, and working through the heaps of papers involved, deserves credit which should go particularly to the senior research associate, Dr Ray Kemp. On the analytical front, it is the treatment of the 'internal' features of the inquiry, such as the innovative introduction of an inquiry counsel, the 'top table', and the 'side-room meetings', which is worked out especially convincingly. Another strong point of the book is the coverage of the legal background.

The aims of the authors, however, go far beyond the provision of a descriptive account of the inquiry with limited examination of its legal aspects and the roles of the individual actors. They set out to give an authoritative account and a comprehensive analysis, explaining the course and the result of the inquiry, and to provide recommendations for the future. It is measured against these more ambitious claims that the book must be considered a failure.

No integrated theoretical framework is developed to analyse the inquiry. Some individual snippets of social science theory are alluded to, but reference to them is patchy and marginal. The questions raised by these theoretical points are pursued separately, so much of the analysis remains rather disjointed. We find a normative–legalistic evaluation of criteria of fullness, fairness and thoroughness going hand-in-hand with attempts to see the inquiry as a means to gain legitimation for a predetermined decision. Both approaches also have to compete against an implicit policy orientation, which is never developed theoretically, analysing the inquiry essentially as an adminstrative tool.

As a result, there are some glaring contradictions. For example, the reader is told fairly early in the book that the outcome of the inquiry was "inevitable" because the "technology, its supporting organizations and the people involved were just too powerful, too big and too committed to be deflected" (p.39). One chapter later, however, we learn that the public inquiry cannot just be regarded as a place for objectors to let off steam, but that it is an "extra-parliamentary device for political debate where conflicts of interest over principles and priorities of natural import can democratically be played out" (pp.52–53). No explanation is furnished of the "democratic" nature of such an exercise. Further, there is a range of suggestions for future public inquiries with the aim of making them, amongst other things, more "efficient". In the light of the previous thesis on the "inevitability" of the outcome, one is bound to ask who would benefit from more "efficient" ways of conducting such inquiries.

O'Riordan and his colleagues see the main result of the Sizewell B inquiry as being its lasting effect on the management of nuclear projects and the conduct of the licensing process. This aspect of the inquiry's ramifications is well worked out and convincingly argued. But, apart from rationalization of the nuclear sector's own procedures, has the inquiry managed to gain legitimacy for a nuclear project whose inevitability the authors consider to have been established before and outside the inquiry? On this point, the book is very weak. While it is said that the factors determining the outcome of the inquiry are to be found outside the inquiry itself, no effort was made to investigate them more fully. Scant attention is given to the state of the nuclear industry and the anti-nuclear movement. Although the authors claim to have conducted intensive interviews with "key participants and observers" (p. viii) there is no further reference to these interviews in the book, and no

clear-cut judgement of the inquiry's influence on the future of the nuclear industry and the anti-nuclear movement in Britain. And although there is some assessment of the possible long-term implications of changes to nuclear project management, a discussion of the future public acceptability of nuclear power is absent.

Was the fullness and thoroughness of the inquiry effective in diverting opposition groups from potentially more effective means of protest? What happened to the groups that boycotted the inquiry because of its alleged unfairness? How can we explain the combination of a perceived unfairness, both in terms of the imbalance of resources between proponents and objectors, and the alleged predetermination of the outcome, with the apparent lack of public response to its conclusion? These questions are not seriously addressed. The book provides a thorough and authoritative account of the inquiry proceedings, but the final evaluation of the effects of the Sizewell B inquiry has yet to be made. □

Immune response

J.R. Batchelor

Milestones in Immunology: A Historical Exploration. Compiled by Debra Jan Bibel. *Sci Tech Publishers, 701 Ridge Street, Madison, Wisconsin: 1988. Pp.330. $35. Distributed outside North America by Springer-Verlag, DM64, £21.*

COMPILING an anthology of scientific papers judged to be milestones in a subject can be a stimulating occupation on a winter's night, particularly in company with argumentative friends. Of course there will be areas of agreement as to what should be included and who made a particular observation, but strong disagreements are also likely to be voiced. Debra Bibel's *Milestones in Immunology* is therefore a provocative as well as an informative book.

To our shame, few of us read original articles published more than five or ten years before we started work on our own doctoral theses, particularly if they are not concerned with the limited fields in which we are engaged. This failing accounts for much of the dull incoherence and the narrow perspectives to be found in the introductory historical chapters of those same theses. Dr Bibel's book provides a partial solution. She has selected her 'milestone' papers, grouped them loosely into nine sections (immunotherapy, immunochemistry, cells and interactions, and so on), provided long excerpts of the papers, and accompanied them with commentaries on both the science and authors.

There is much to enjoy here, according to individual tastes. For example, I found it interesting to be reminded of the extraordinary bureaucratic resistance to the introduction of prophylactic immunization against typhoid for British soldiers at the beginning of the twentieth century, a measure advocated with much spirit by Almroth Wright. There is the concise logic of Linus Pauling's paper on the structure of antibodies in which he assumes, with Marrack, Heidelberg and others, that because antibody can form a precipitate on combining with antigen, the antibody molecule must have two combining sites. "The rule of parsimony (the use of the minimum effort to achieve the result) suggests that there are only two such regions, that is, that the antibody molecules are at the most bivalent". The fact that there is an exception to this rule, and that the 'instructive' theory of antibody formation he proposed in the paper is wrong, does not detract from the interest. There are, too, some apt or ironical quotations introducing the chapters. For example, the line from Edmund Burke ("Our antagonist is our helper") or that from Paul Anderson ("I have yet to see any problem, however complicated, which when you looked at it in the right way, did not become still more complicated").

In spite of many attractive features of the book, there are aspects which I found disappointing. To a large extent they are inherent in treating a scientific enterprise as if it consisted of a series of pedestrian studies, too dull to be noteworthy, punctuated by the inspired contributions of a few outstanding people.

Dr Bibel will not escape the charges of oversimplification and, at times, even injustice. To select one of G.D. Snell's papers describing a strategy for identifying the alleles of minor histocompatibility system genes in a series of congenic mouse strains, and use this as a reason for placing his work in the section on technology, is admitted by the author as likely to invite criticism; but it mistakes a branch for the whole tree and those who do not already know of the studies of Snell and his colleagues would not, from this book, be able to appreciate their theoretical significance. In my view, the importance of C.C. Little's hypothesis, formulated early this century — that progressive growth of transplanted tumours depended upon graft and host sharing multiple, independently segregating genes — should have been recognized. The hypothesis provided the motive for the development of inbred strains, which were needed to test Little's theory. Snell's great achievement was that he placed these genes into separate linkage groups, determined the extent of their polymorphism and defined their relative influence upon graft survival. This achievement led to the concept of each species having a single major histocompatibility system and multiple minor systems, as well as providing many invaluable mouse strains as tools for research.

In the description of Peter Gorer's work, Dr Bibel comments briefly:

> His new finding, however, was the correlation of resistance to tumor transplantation to the absence of a particular blood group antigen. He offered tumor studies an immunological perspective, and provided the first linked marker of histocompatibility.

Few would guess from this remark how clearly Gorer's experiments had shown that the fate of a transplanted tumour depended on whether or not the recipient mice mounted an immune response against antigen II expressed by the tumour. And it seems strange that after Gorer had thus demonstrated the immunological basis of graft rejection, Dr Bibel does not cite his pithy conclusions:

> Normal and neoplastic cells contain isoantigenic factors which are genetically determined. Isoantigenic factors present in the grafted tissue and absent in the host are capable of eliciting a response which results in the destruction of the graft. Under special circumstances the response may not be elicited or grafted tissues may not be destroyed thereby.

I also miss acknowledgement of the work of so many scientists who deserved to be mentioned. For example, in the commentary on Jean Dausset's discovery of human leukocyte alloantibodies, and the analysis of the HLA system carried out at the international workshops, there is no recognition of how the success of these analyses depended critically on the solution of at least three problems. First, van Rood showed how to recognize antisera containing antibodies of the same specificity, using computers to perform the large number of χ^2 tests required. Second, Walford and colleagues discovered that rabbit complement allowed Gorer's lymphocytotoxicity test to be used with human reagents, thus providing a reliable test. Third, Terasaki and co-workers invented the 'micro' version, thus permitting small amounts of defined antibody reagents to be used by many laboratories for standardization purposes. None of these was a small achievement. Each is an example of how misconceived it is to imagine that progress in understanding depends upon the efforts of a few; the reality is that it is due to the applied talents of the many. □

Life and loves of a Martian pioneer

Peter Kemp

Genesis: An Epic Poem. By Frederick Turner. *Saybrook, 4223 Cole Avenue, Dallas, Texas 75205: 1988. Pp.303. Distributed by W.W. Norton, pbk $9.95.*

INSPIRED by such varied sources as Homer, James Lovelock's Gaia hypothesis, the Bible and the Wisconsin Arboretum's success in turning degraded farmland into prairie, Frederick Turner's *Genesis* is a work of considerable compass. Aiming to synthesize old and new, art and science, it tells in epic verse the story of the colonizing of Mars: as the settlers contrive to transform an arid planet into garden, Turner seeks to re-fertilize an apparently defunct genre.

His task is as risky as it is ambitious and, conscious of this, he equips his epic with defence mechanisms. This 10,000-line saga is, we are informed, the work of a twenty-first-century poet living under mild-ish totalitarian conditions then prevailing on Earth. A martyr to arthritis and despondency, he is painfully aware that his verse lacks polish. Also, we are warned that in the process of projecting it into Turner's cortex — exactly how is not explained — clumsiness may have crept in. Further intimating that the poem should be handled with kid gloves is a heartfelt evocation — "Poor science-fiction. Last muse of the gods . . ." — lamenting the unjustly despised status of this type of writing. As a final deterrent against criticism, the poem features as its most repulsive character a reviewer who has "A Shiite mullah's openmindedness, /A moral backbone of boiled watercress;/All the prophetic vision of a sheep".

At risk of seeming such a mix of bigotry, salad and mutton, it has to be said that the poem is uneven. Its best stretches are its landscapes. Turner sensuously excels at evoking atmospheric terrains — from the wind-scorched Australian outback to Mars at different stages of its ecogenesis: the "golden furs and powdery crimsons" of mosses and lichens spreading over "glitterings of slime and foams", blossoms gorgeously exploding into newly oxygenated air.

But, along with this flair for dramatizing the processes of life-formation and evolution, goes an enfeebling inability to create and develop lifelike characters and situations. The poem is peopled by melodramatic puppets. Resembling the plastic personnel of some *Star Wars*, they range from evil Gaea, perfidious leader of the Ecotheist Movement, which teaches that nature must never be interfered with, to noble Chance, her estranged husband, dedicated to bringing life to Mars. As battle-ships, a space Ark and a displaced ice moon of Saturn hurtle round the Solar System, freedom fighters, visionaries, gladiators, lurid villains and a miracle-working prophetess engage in comic-strip adventures.

Bizarrely, Turner's celebration of advanced biotechnology is studded with throwback violence: hand-to-hand fights, karate chops, disembowelling. Martial arts loom as large as Martian pioneering in his story. Incongruity keeps breaking through the attempt to combine sophisticated scientific lore with the barbarities traditional to epic literature: wars, parricide, split families, blood feuds, vengeance.

The poem's classic *in medias res* opening finds an appropriate out-of-this-world parallel to the *Iliad*: helmeted figures in metallic uniforms clash on the deadly plains of Mars. But despite the subsequent efforts to elevate proceedings by using the apparatus of the epic — heroic similes, addresses to the muse, cataloguings of troops — bathos often intrudes. After an assassin returns from a mission to kill the Sibyl at her shrine in the Peacock mountain on Mars, it comes as an anti-climax to hear of his booking into a "clean hotel just west of Reading". Behaviour oscillates between the cosmically marvellous and the comically mundane. The switches of language also jar, with abrupt changes from laboratory terminology ("volatile calyptral ribosomes", "synthesized endorphins", "heterodyning frequencies") to musty archaisms ("And ruddy Phoebus gins to welke in west"). And it seems a shame that the twenty-first-century poet, though familiar with the intricate mechanisms of planetary engineering, has not always worked out ("tech-/Nical", "psych-/Ologically", "choc-/Olate") how to fit his words neatly into pentameter lines. □

Peter Kemp, 61 Princes Avenue, Finchley, London N3 2DA, UK, is lead fiction reviewer for the London Sunday Times.

We've got rhythm

Asa Briggs

The Metronomic Society: Natural Rhythms and Human Timetables. By Michael Young. *Thames & Hudson/Harvard University Press: 1988. Pp. 301. £16.95, $25.*

MICHAEL Young, whose book *The Rise of the Meritocracy* fascinated readers a generation ago, has produced another remarkable and equally stimulating book which deals with even more basic issues. It is designed to be read by a wide audience, and it abounds in memorable phrases and descriptions. "Durability is not durability unless it is pulsating." "Habits are not usually chosen with any deliberation; they just grow, wild flowers rather than cultivated ones." "A habit is a memory unconsciously edited for action." "The fertility of nurture festoons itself around nature." "Time is immanent in everything . . . . You cannot catch it because you already have it." In the broadest sense this is a book for everybody, rich both in analogies and in insights. It deals in various degrees of detail with such topics as time, memory, tradition, habit and custom. It begins with an analysis, continues with a set of explanations and ends with a prescription.

The term "metronomic society" is not introduced until the end of the first chapter, where we are told that "modern society (and social science with it) . . . has a linear bias to it, and that with this linear bias many natural rhythms have been replaced by artificial ones, a rhythmic society replaced by a metronomic". The second chapter, which begins by noting how the living organism has long been one of the favourite analogies for society, examines more fully the nature of the natural rhythms. It summarizes research, not all of it completely convincing, on an internal biological clock, while adding that it will not be conclusive until the clock or clocks shall be found.

Lord Young then turns to social behaviour and how it is timed, drawing the necessary contrasts both between natural rhythms and artificial rhythms and between animals and human beings: "bees and birds do not celebrate Sundays". Regularities, both natural and artificial, "create the social mesh", but "particularly within large and complex organisations, biological and social rhythms are in conflict with each other". The fourth chapter, "Habit: the Flywheel of Society", is the most original, although the term habit is used very generally to cover phenomena which are only differentiated at the end of the chapter (via the *Encyclopedia of Social Science*) into motor habits, cognitive habits, emotional habits and moral habits. It would have been more persuasive if the differentiation had been introduced from the outset, for the various activities that Lord Young uses as examples of habit suggest differences more than similarities. The conclusions are firm, however — "Habit is a means of making learning stick"; "Habits constitute the rules of individual behaviour and customs the rules of social behaviour".

There is a darwinian ring to the last paragraph of the fourth chapter, which sets the scene for the following discussion of "Social Evolution". This is a less original chapter. It deals with speech, law and institutions, taking the British monarchy as the example, and notes how "despite and because of the hold of habit, institutions can evolve" and how in each

case "change comes not by a wholesale overthrowing of the past but by leaning against the past to gain a kind of leverage and add something new to it". A glance at another Young, G.M. Young, might have been useful here. Even so, Lord Young, who draws most of his analogies from biology, has some useful comments to make about history. In comparison economics throughout gets short shrift, even in the brief section "The Question of Progress", and even though economists have been particularly interested, as the author observes *en passant* earlier in the book, in cycles and in 'trends' (a term he does not use).

Nonetheless, Chapter 6, "The Metronomic Pulse", begins with economics although it is approached ritualistically rather than analytically, and later turns to a point made by a number of economists that "the axiomatic and automatic consequence of a rising standard of living is that time becomes scarcer". For Lord Young the position is more serious than they suggest, for "the symptoms of the famine are all around us" and (a memorable phrase) "the more deliberation there is, the more deliberation is necessary". The thought leads, in linear fashion, to the prescriptions of the last chapter — reintroducing "more of the cyclical into the evolutionary mix" and giving "a more prominent place once again to the cycles of nature". The penultimate section is called "Back to Circadian Rhythms", the last "Escape from the Grid". The titles speak for themselves. To anyone suffering from time famine the prescription is attractive, and there may be reasons different from those advanced by Lord Young for following it. He does not quite say, however, how to do so.

Within the book there are running arguments with sociologists about the nature of sociology, at least one dig at anthropologists, and freely acknowledged processes of borrowing from biologists. Indeed, while expressing distaste for sociobiology Lord Young shows himself to be an eloquent spokesman for his own version of social darwinism. He has great social concern, however, and is untouched by determinism. One word he never uses about human beings is curiosity — perhaps because he has so much of it himself.

Lord Briggs is Provost of Worcester College, Oxford OX1 2HB, UK.

Infant individuals

George Butterworth

Nature and Nurture During Infancy and Early Childhood. By Robert Plomin, John C. DeFries and David W. Fulker. *Cambridge University Press: 1988. Pp 345. £30, $44.50.*

In this book, Robert Plomin and his colleagues employ quantitative behavioural genetics to explore the origins and development of individuality during infancy and early childhood. They analyse "the nature of nurture" to study genotype–environment interaction and correlation, and the genetic mediation of environmental influences, rightly stressing that their methods yield totally different information to that obtained by research on group averages. The second approach consigns individual differences to error variance, whereas the first respects natural variation as being at the very foundations of individual development.

Behaviour genetics involves detailed and rather technical statistical analyses of twin and adoption studies. Twin studies, in which identical and fraternal twins are contrasted, enable estimates of the components of variability due to genetic or environmental effects. Adoption studies, on the other hand, allow the possible covariation between genes and environment to be teased apart. Genetically unrelated individuals adopted into the same family will resemble each other for environmental reasons only. The effects of the remainder of the non-shared environmental variance, such as differential maternal attention between siblings, can also be estimated.

Height and weight, obvious physical variables, are often used to 'anchor' cognitive and behavioural measures. Height, for example, shows a strong correlation from infancy to early childhood, with genetic and environmental effects differing at various times in development. Fraternal twins are actually physically more alike than identical twins at birth, but not at six months, perhaps because identical twins may be subject to greater intra-uterine competition for nourishment through the chorion. Adopted siblings also show significant correlations for height during the second year of life, although these values are not as high as for fraternal twins. Hence, for physical variables it is possible to distinguish genetic effects, effects of the shared twin environment and effects of non-shared environmental factors.

Cognitive or personality development is, of course, more variable than physical development. IQ scores are notoriously unstable from infancy to early childhood, at least in part because of the different sensori-motor and verbal items on the tests. Genetic influences on IQ may be greatest between the ages of one and two years, while shared environmental factors, as assessed through adoptive siblings, may account for more of the variability between IQ in early childhood. The Colorado Adoption Project (CAP) analysed here also shows that shared environment may be of lesser importance for the development of temperamental characteristics than non-shared environmental effects. An odd, unexplained result of the CAP study was that the amount of television viewing at three and four years of age may have a heritable component; a significant correlation was found on this variable between adoptive siblings.

In the final chapter, the authors consider the "nature of nurture". The appropriate behavioural genetic design for such a study would involve quantifying the parenting behaviour of adult identical and fraternal twins as well as data from twin children and their parents. Genetically mediated differences in parenting, as revealed by differences between identical and fraternal twin parents, may have differential effects on their children. Genetic differences among children may also contribute, and the differential effects could be quantified because the children of identical twins are related to each other as half-siblings, whereas the children of fraternal twins are cousins. Parents and children share 50 per cent of their genes, regardless of whether their twin children are identical or fraternal, and this again yields the possibility of contrasting differential effects on development. Unfortunately, there are no data on these contrasts; in the book they seem to be mentioned as a behaviour geneticist's methodological ideal. But adoption studies do offer some evidence that maternal involvement — in encouraging development, for example — correlates more highly with IQ in non-adoptive siblings than in the adoptive child. The authors suggest that this may be explained as a genotype–environment correlation whereby the greater genetic match between the mother and her biological child facilitates development.

The book contains descriptions of many hundreds of observations on the complex inter-relationships between heredity and environment, and they illustrate well the ingenious ways in which the components of individual variation can be disentangled. The authors have made a great deal of progress beyond the stark genes versus environment dichotomy of earlier behaviour genetics. Whether the greater sophistication of partitioning will satisfy those who espouse a holistic approach to individual development remains to be seen; but at least the inter-penetration of nature with nurture has been acknowledged. □

Graduates — for better, for worse

J.M. Ashworth

Should a university be devoted solely to teaching? Data from the University of Salford suggest that such an institution would be unlikely to produce good graduates.

BRITISH universities receive grants from the state through the University Grants Committee (UGC) which they use to support both the education of undergraduates and the research of their staff. The British government has suggested that universities should account separately for what they spend on research and on teaching, which has given rise to a debate on the extent to which the quality of undergraduate teaching requires that those doing the teaching should also be carrying out research.

In a recent report[1], the Advisory Board for the Research Councils (ABRC) recommended that British universities should be classified into groups, with one group (type T) being defined as those that are unable to provide comprehensive facilities for research. The government has rejected this advice, but many fear that such a policy may be introduced by stealth as a result of the current UGC reviews of university departments of subjects such as physics and chemistry. The UGC will be replaced by the new University Funding Council (UFC) in April 1989, and it is this body that will have to decide whether or not to implement the recommendations of the reviews.

Lack of data

The debate has been marked by a lack of data. Those who believe that high-quality teaching can be carried out only in a university which is also a research centre have been placed at a disadvantage by the fact that, although it is relatively easy to adduce anecdotal evidence for the proposition that 'not all good researchers are good teachers' (or vice versa), it is not easy to demonstrate that good teaching depends on good research. It is the purpose of this article to provide such a demonstration.

In July 1981 the UGC informed the University of Salford that the quota of British students the university was expected to admit was to be reduced by 30 per cent, and that the recurrent grant that the university had been expecting to receive over the next three years would be reduced by some 44 per cent. This precipitated a crisis: the salaries of approximately a third of the staff could no longer be paid from UGC funds, and most of those concerned retired prematurely. Efforts were also made to obtain funds from other sources, and these have been relatively successful; the university's income is now larger in real terms than it was in 1981, more than half of it coming from sources other than the UGC recurrent grant. What is less well known are the consequences that this restructuring has had on teaching in the university.

Honours degrees awarded by British universities are graded into classes. One measure of the quality of a university is the fraction of its graduates who obtain first-class degrees. Another is the 'average' class of degree, calculated by assigning a value of 5 to a first-class degree; 4 to an upper second; 3 to a lower second; 2 to a third; and 1 to a pass degree and then dividing this sum by the total number of graduates. The first of these measures can be taken as an indication of the extent to which a university acknowledges the exceptionally good student, and the second the extent to which it caters for the average student. Figure 1 (see over) shows how these measures have varied at the University of Salford since 1980; both have shown considerable improvement, but the change in the 'average' class of degree is, statistically, the more significant. In the analysis that follows, I have used these measures of student achievement as indicators of teaching effectiveness; both give the same outcome.

The improvement shown in Fig. 1 is surprising, for the number of academic staff (Table 1, column 1) fell by slightly more in percentage terms than did the number of undergraduate students in the same period (Table 1, column 4). Moreover, this smaller staff was under great pressure to obtain research grant and contract income from non-UGC sources, in which they were very successful; the research income of the university and the income of the commercial company (Salford University Business Services Ltd), whose profits are covenanted to the university, have both increased considerably (Fig.2). But how can a smaller number of academic staff, doing more research and consultancy, nevertheless construct an environment in which graduates obtain better classes of degree?

Explanation

The first possible explanation is that the standard of the degrees awarded by the university declined after 1981. This cannot be completely ruled out, but it is highly improbable. All degrees at the university are moderated by external examiners; in any year, about 60 examiners drawn from a wide variety of British universities and industries are involved in our examining boards. A conspiracy to reduce standards steadily over a period of years on the part of so many different professional people (most of whom are strangers to one another) is difficult to imagine.

If the quality of the university's degrees has remained constant, explanations of the changes shown in Fig. 1 must be due either to an increase in the quality of the students admitted or to an improvement in the effectiveness with which those students are taught.

In Britain, the school-leaving examinations (A-levels) are graded A–E; all universities require a minimum of two E-grade passes in two subjects at A-level for admission. Different grades can be given numerical values (A=5, B=4, C=3, D=2, E=1) and thus an 'average' A-level grade of the population of students admitted can be determined. In Fig. 3 the average A-level grade obtained by the entering students is plotted as a function of the year of

Table 1 Changes in the numbers of undergraduate students and graduates (of all kinds) at the University of Salford, 1980–1 to 1987–8

Academic year	1 Full-time UGC-funded staff	2 Full-time graduate students	3 Departmental research assistants	4 Full-time undergraduates	5 Total graduates*	Under-graduates/ graduates†
1980–1	469	336	130	4,205	935	4.5
81–2	467	286	123	4,014	876	4.6
82–3	387	288	158	3,731	833	4.5
83–4	348	362	124	3,342	834	4.0
84–5	328	423	169	3,154	920	3.4
85–6	346	517	184	3,104	1,047	3.0
86–7	344	498	201	3,151	1,043	3.0
87–8	335	580	197	3,245	1,112	2.9

* Sum of columns 1,2 and 3. † Column 4/column 5.

admission. Comparison of Fig. 1 with Fig. 3 shows that there is an approximately three-year lag between the rise in the A-level grades of the students admitted and the rise in the standard of degrees awarded. Because most undergraduate degree courses at Salford last three or four years, this suggests that the increased quality of the output is a result of the increased quality of the input. But closer examination reveals that this cannot account for more than a small fraction of the change. First, a sizeable fraction of Salford students (15–24 per cent, depending on the year) have entering qualifications other than A-levels (usually Business and Technician Education Council awards from colleges of further education). Such students obtain first-class degrees in at least the same proportion as their representation amongst the graduating class.

Second, the correlation between the class of degree awarded to a student and the A-level grades that that student had on entry three or four years previously is as poor at Salford during the 1980s as it has been previously[2], or as it is reported to be by other institutions[3]. So although the increased academic attainments of most of those admitted to the university undoubtedly contribute to the increase in the quality of the output, the relationship is not simple, and neither can it account for more than a fraction of the changes shown in Fig. 1.

At least as important seems to be the nature of the environment in which the students are taught. In 1982, as part of the process of adaptation that the university had to make to the loss of so much of its UGC support, the senate adopted specific and quite detailed "Aims and Objectives". The section in this document headed "Teaching" states:

The university's teaching is intended to result in graduates . . . with certain . . . characteristics:

(a) the capacity to acquire, organise and systematise knowledge and thereby to develop what the Robbins Committee called 'the general powers of the mind';

(b) the capacity to appreciate, to value and to make judgments of what is beautiful, of good repute and fit for its purpose. This involves the education and training of feelings and emotions as well as implying a moral or ethical framework within which (a) above must be attempted;

(c) the capacity to identify, formulate and then to solve problems and to make, design, organise, produce or construct useful objects and services;

(d) the capacity to co-operate with others, to value communal endeavour and achievement as well as competition.

Although the first two of these objectives are common to most universities, at Salford we believe that the other two are distinctive and that they encapsulate the university's purpose to 'educate for capability'.

This philosophy has helped to shift the

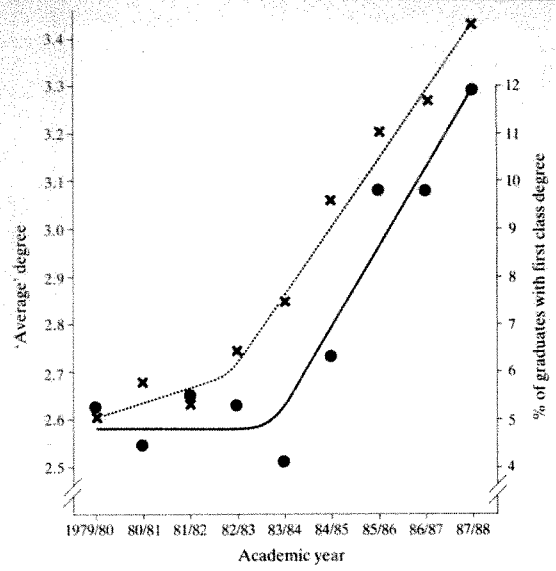

Fig. 1 Degrees awarded by the University of Salford between 1980 and 1988. The 'average' class of degree (crosses) is calculated by assigning a value of 5 to a first-class degree down to 1 for a pass degree, and then dividing the sum by the total number of graduates. The percentage of graduates obtaining a first is plotted by the circles.

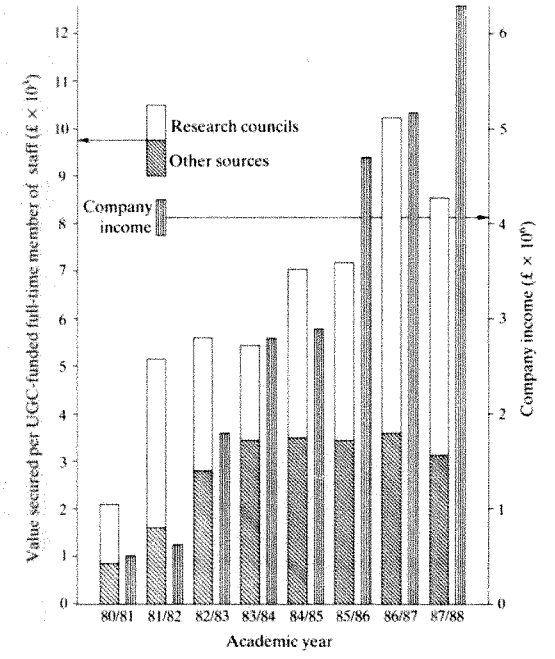

Fig. 2 Research grant and contract income of University of Salford staff, and gross income of the university's wholly owned companies, between 1980 and 1988.

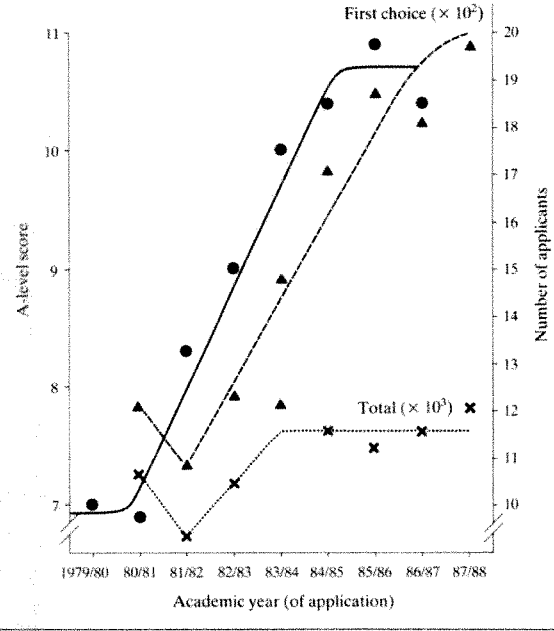

Fig. 3 Characteristics of undergraduate entrants to the University of Salford, and of applications for entry, between 1979 and 1987. Average A-level score of all subjects offered by entrants (circles) is calculated by assigning a value of 5 to an A+ grade down to 1 for an E+ grade, and then dividing the sum by the number of entrants. Total number of applications through the Universities Central Council for Admissions (UCCA) is plotted by the crosses, and number of those who selected Salford as their first choice, of five universities, by the triangles.

emphasis of the university's staff away from a preoccupation with teaching students to a concentration on supporting their capacity to learn — away from an expectation that the university teacher's duty is personally to carry out the teaching, to a realization that the job is much more managerial in nature. Moreover, the success of the university in attracting research contracts (Fig.2) meant that although the number of academic teaching staff (those financed by UGC) declined, the number of full-time postgraduate students and research assistants paid for out of that income increased. The changes are shown in Table 1. These categories of staff and student have been increasingly involved in teaching.

During the 1980s there has thus been a conscious change in the ethos of the university which has profoundly affected the nature of the teaching offered to undergraduates. The best measure of this change is, I believe, the changing ratio of undergraduates to graduates (of all kinds). The ratio changed, as is shown in Table 1, from 4.5 to 2.9 in the period 1980–1988, but that figure understates the true change; the university now employs many more part-time teachers (many of them former full-time employees who have taken early retirement) and has also been much readier than before to employ industrialists of all kinds in teaching. In 1980–1981 the university spent £46,000 on such part-timers; in 1987–1988 £413,600. The link between teaching and research has thus not been so much individual teacher/researchers as the junior associates whom good researchers are able to employ and who have helped both to change the ethos of the institution and to carry out more of the teaching.

Degree scores

Multiple regression analysis of the degree scores in various departments at different times during the past decade can be used to determine the extent to which the change in A-level grades of the intake and the ratio of undergraduates to graduates have contributed to the changes shown in Fig. 1. Such analyses should not be taken to imply causality or even that the relationship is of the same kind in the many different departments. Among other things, we find:

- In the engineering faculty, 46 per cent of the variance can be accounted for, with the main factor being the ratio of undergraduates to graduates.
- In the science faculty, 55 per cent of the variance can be accounted for, with the main factor being the A-level grades of the intake.
- In the social science and arts faculty, only 13 per cent of the variance can be explained and here, as with engineering, the main factor is the undergraduate to graduate ratio.

The so-called linear subjects, recognizably similar to those taken at school, are found predominantly in the science faculty at Salford, so that these results are not unreasonable.

Over the university as a whole, it is clear that the ratio of undergraduates to graduates has had the main effect (the engineering faculty is the largest at Salford). But nearly half of the variance remains unaccounted for.

One factor which must be important, but which is difficult to quantify, is the motivation of the undergraduates themselves. In Fig.3, the total number of applications for admission to the university through the Universities Central Council for Admissions (UCCA) has been plotted together with the number of applicants placing Salford first (out of the five choices permitted in the UCCA system). Although the total number of applications has been approximately constant, the number expressing a preference for Salford has increased throughout the period. This factor must be correlated to some extent with motivation and, statistically, may account for some of the unaccounted variance. But it would be naive to conclude that there is a direct causal relationship between degree class and university preference as expressed on the UCCA application form.

Unfortunately, a change in the UCCA system has meant that students are no longer expected to express any preference between their five choices, so this kind of analysis cannot be extended beyond 1988.

No other readily available management statistic seems closely correlated with the changes shown in Fig.1 although several (such as library use, frequency of borrowing of books and use of computing time, all measured on a *per capita* basis) have increased significantly during this period. A longer run of data, ideally on a departmental or with an individual student basis, will be needed to carry this analysis further and is planned.

The quality of the degrees awarded by the University of Salford has increased markedly during a period of great upheaval, when the number of experienced academic staff was falling both absolutely and in terms of student to staff ratio, and when the demands placed on staff to obtain support from sources other than the UGC for their research (and other) work were intense. This increase in quality is shown both in the performance of those exceptionally good students who obtain first-class degrees and in the 'average' degree awarded. Increases in quality are seen in every faculty and department, and are clearly the result of institutional changes which have affected everyone.

The UGC and other central planning bodies in Britain rarely take into account institutionally based indicators of performance of the kind reported here. Rather, they consider groupings across disciplines, or 'cost centres', from a national perspective. So such central reviews can rarely detect the changes in institutional ethos which, if the arguments in this paper are accepted, are those most relevant to teaching performance.

Correlation

At Salford, the two changes closely correlated both in timing and extent with the improvements of the quality of the degrees awarded are the improvements of academic performance of entering students and the changing ratio of undergraduate students to graduates of all kinds. The former change is of more significance in the science faculty (departments of mathematics and computing, physics, chemistry and biological sciences) and the latter in the faculties of engineering and social science and arts. Yet for individuals, good A-level grades at entry have been no better predictors of class of degree during the 1980s than at previous times, at Salford and elsewhere[2,3].

It is therefore clear that the main factor underlying the improvements shown in Fig.1 is the change in the ratio of undergraduates to graduates, which in turn is a consequence of the increased effectiveness with which the university's staff have obtained research grants and contracts from research councils and from industrial and other sources. This has been the link between 'good teaching' (as measured in Fig. 1) and research at the University of Salford in the 1980s — together, of course, with the adoption of an explicit philosophy of education ('education for capability') which encouraged and sanctioned the use of the young research assistants and graduate students in the teaching programmes of all departments.

It has been suggested that universities which do not offer the full range of research facilities might be established in Britain[1]. This has been interpreted by some to mean that 'teaching-only' universities may evolve. The evidence presented here suggests that such institutions, if established, would be unlikely to produce good graduates as conventionally defined. On the contrary, it would seem that the best way of increasing the teaching effectiveness of a university in Britain is to encourage the staff to do more research and simultaneously to encourage the adoption of a philosophy of education which places more emphasis on student-centred learning and less on staff-centred teaching. □

I am grateful to Dr Rose Baker of Salford University's Academic Information Services for help with the statistical analysis.

Origin of the anomalous ^{40}Ar–^{39}Ar age of Zaire cubic diamonds: excess ^{40}Ar in pristine mantle fluids

M. Ozima*, S. Zashu*, Y. Takigami* & G. Turner†

* Geophysical Institute, University of Tokyo, Tokyo 113, Japan
† Department of Physics, University of Sheffield, Sheffield, UK

Cubic diamonds from Zaire show excellent correlations between potassium content and $^{40}Ar/^{36}Ar$ ratio, and between $^{40}Ar/^{36}Ar$ and $^{39}Ar/^{36}Ar$, which can be interpreted to yield an 'isochron' age of about 6 Gyr. Now the discovery of a correlation between chlorine content and ^{40}Ar, together with recent mineralogical and geochemical work concerning the origin of cubic diamonds, strongly suggests that the ^{40}Ar is an excess component which has no age significance, and that the ^{40}Ar and its associated potassium are contained in sub-micrometre inclusions of mantle-derived fluid.

ZASHU *et al.*[1] have reported that ten cubic diamonds from Zaire yielded excellent linear correlations in both ^{40}Ar-K and $^{40}Ar/^{36}Ar$ versus $K/^{36}Ar$ diagrams. If the linear arrays are assumed to be isochrons—which is the basic premise in K-Ar dating—the corresponding ages would be about 6 Gyr, which is older than the age of the Earth. The excellent reproducibility of these results precluded experimental deficiencies; Zashu *et al.* were therefore forced to suggest that either: (1) the ^{40}Ar in the diamonds is excess ^{40}Ar and has no age meaning; (2) the basic assumptions underlying the K-Ar dating method, such as the constancy of the $^{40}K/K$ isotope ratio and of the decay constant λ_e of ^{40}K, were not satisfied; or (3) the diamonds or the inclusions in the diamonds are pre-solar. In regard to the second possibility, Akagi and Masuda[2] and Podosek *et al.*[3] analysed Zaire cubic diamonds from the same group used for the K-Ar dating, and found normal K isotope composition. These results also rule out the possibility of a change in λ_e, leaving only the possibilities of excess ^{40}Ar (1) or a pre-solar origin (3). We applied ^{40}Ar-^{39}Ar step-heating dating to four Zaire cubic diamonds from the same group as those used in the previous K-Ar dating[1] and K isotope studies[2,3]. The results showed excellent correlation among ^{40}Ar, K and Cl. Correlation of Cl with ^{40}Ar, together with recent mineralogical and geochemical work concerning the origin of cubic diamonds[4,5], strongly suggests that the anomalous ^{40}Ar and its associated potassium are contained in sub-micrometre inclusions of mantle-derived fluid.

Samples and experimental details

The samples are cubic diamonds from Zaire and are believed to come from the same group as those in the previous studies[1-3]. All the samples show a very regular cubic shape of ~4 mm on a side, but their colours differ from dark brown to brownish, yellow and almost white. Two stones from the same batch were cut in half. Cathodoluminescence images of the cut sections revealed an internal zoning consisting of a coat and a core. This structure is quite similar to those reported on several cubic diamonds by Boyd *et al.* (Fig. 1 in ref. 5).

Diamond samples were irradiated by a total neutron flux of $\sim 3 \times 10^{18}$ neutrons per cm^2 (irradiation parameter $J = 1.709 \times 10^{-3}$ for sample 87N01 and $J = 1.91$–1.83×10^{-3} for samples 88N01-03) with standard samples MMHb-1(6), K_2SO_4 and CaF_2. Before the stepped-heating analysis all samples were heated to 200 °C for 6 hours in an attempt to remove adsorbed atmospheric argon. Except for sample 87N01, for which only two temperature fractions were taken, four temperature fractions were taken for each sample: the samples were kept at each temperature step for 30 min for noble-gas extraction. The experimental procedures for noble-gas extraction, purification and mass-spectrometric analyses are similar to those described previously[7,8].

Results

One of the conventional ways of plotting ^{40}Ar-^{39}Ar data is in the form of 'age spectra'. Because more than 90% of the argon from the diamonds is released in a single temperature step around 1,900 °C, at which point the diamonds are graphitized, there is little to be gained by presenting the data in this form except to note that in most instances the individual ages agree, within error, with the previously reported K-Ar isochron ages of ~6 Gyr. We choose instead to present the more informative isotope-correlation plots[9]. The first of these, Fig. 1, is a conventional isochron plot of $^{40}Ar/^{36}Ar$ against $K/^{36}Ar$. We have adopted the practice of plotting molar ratios, as this seems the most logical way of comparing elemental ratios with isotope ratios (which are invariably expressed in molar terms). The linear correlation in Fig. 1 suggests that ^{40}Ar is derived from sites occupied by K, implying that it is an indicator of age. The age

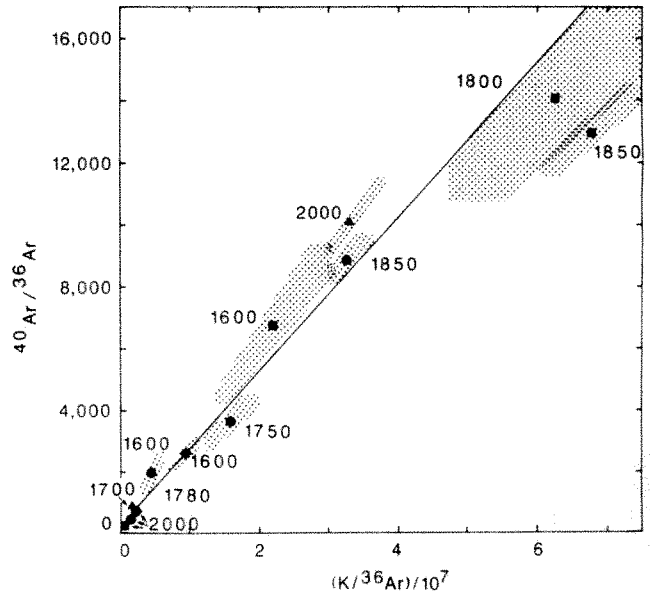

Fig. 1 $^{40}Ar/^{36}Ar$ versus $K/^{36}Ar$ isochron plot. The ^{40}Ar-^{39}Ar age inferred from the slope of the line corresponds to 5.7 Gyr. Symbols represent different samples: ▲, 87N01; ●, 88N01; ■, 88N02; ◆, 88N03. Numerals indicate temperatures (°C). Shaded areas indicate an approximate 1σ error envelope.

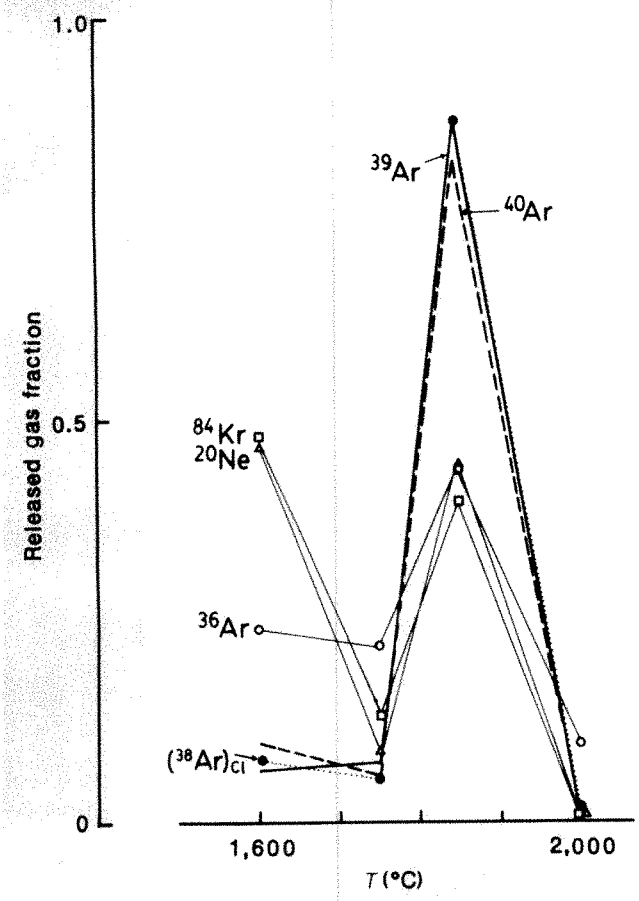

Fig. 2 Thermal-release patterns of noble gases for sample 88N01. $(^{38}Ar)_{Cl}$ indicates ^{38}Ar corrected for trapped ^{38}Ar (equal to 19% of the ^{36}Ar and corresponding essentially to Cl in the diamonds).

calculated from the slope of the line of best fit is ~5.7 Gyr, which is fully consistent with the earlier K–Ar measurements.

In Fig. 2 the fractions of various noble-gas isotopes degassed at each temperature step are plotted against the temperature for sample 88N01. Thermal-release patterns for other samples are almost identical to Fig. 2. The degassing patterns for ^{40}Ar, ^{39}Ar and ^{38}Ar are almost identical, but are distinctly different from those for other noble gases, including ^{36}Ar. This shows conclusively that ^{40}Ar, ^{39}Ar and ^{38}Ar were degassed from similar trapping sites. Because ^{39}Ar is produced by the reaction $^{39}K(n, p)^{39}Ar$, and ^{38}Ar by (n, γ, e^-) reactions of ^{37}Cl, the identical thermal-release patterns for ^{38}Ar, ^{39}Ar and ^{40}Ar indicate that ^{40}Ar was trapped at the same sites as K and Cl. In Table 1 we summarize the analytical data for these ^{40}Ar–^{39}Ar step-heating experiments.

A two-stage growth model

The excellent correlation among ^{40}Ar, K and Cl can be best explained if these elements existed in the fluid phase before having been trapped in diamonds, as elements in such a fluid could be relatively easily homogenized to give rise to a uniform ^{40}Ar:K:Cl ratio. Because of its incompatible nature, ^{40}Ar can be more easily leached from the country rocks into the fluid phase than can be potassium[10]; this would explain the excess ^{40}Ar. If the diamonds trapped such a fluid component to varying degrees, this would give rise to identical thermal-release patterns for ^{40}Ar, K and Cl, and to a linear correlation in the ^{40}Ar–K and ^{40}Ar–Cl diagrams, because they would be trapped as fluid inclusions at the same sites.

Recently, Navon *et al.*[4] studied several cubic diamonds, including two from Zaire, with ion-microprobe and electron-probe analysis, scanning electron microscopy and infrared spectrometry. They observed that coats in the cubic diamonds contain sub-micrometre inclusions which are characteristically enriched in K_2O(8–22%), CaO(6–18%) and other trace elements. The micro-inclusions are composed of 40–70% metal oxides (SiO_2, K_2O, FeO and CaO and smaller amounts of Na_2O, MgO, Al_2O_3, TiO_2, Cr_2O_3, P_2O_5 and Cl), 20–50% water and 10–30% CO_2. Because micro-inclusions were observed commonly in cubic diamonds from various locations, Navon *et al.* suggested that the materials in these micro-inclusions may be related to pristine mantle fluids, which are responsible for widespread metasomatism in the sub-continental mantle.

The difference between the thermal-release patterns of ^{40}Ar, ^{39}Ar, ^{38}Ar and other noble gases (Ne, ^{36}Ar, Kr, Xe) may be explained in terms of a many-stage growth model[5]. Carbon and nitrogen stable-isotope studies suggest that cubic-morphology coated diamonds have undergone two-stage growth: initially a transparent core with octahedral morphology grew in a similar way to common diamonds, and was rimmed by a cubic-habit coat which grew later in contact with the proto-kimerlite host. We suggest that the cores trapped noble gases from the mantle, and that micro-inclusions were incorporated later into the coats during their rapid growth in the presence of fluids. Consequently, the diamonds contain two generations of noble gases: those trapped in the core consist mainly of the normal mantle components, and those contained within micro-inclusions in the coats comprise the excess and *in situ* radiogenic ^{40}Ar.

Units are cm^3 STP g^{-1}.

* The ^{37}Ar peaks were not detected (ND) because of a long time interval (~2 yr) after irradiation. However, the correction necessary for these has negligible effect on the apparent age because the ^{40}Ar content is much larger.

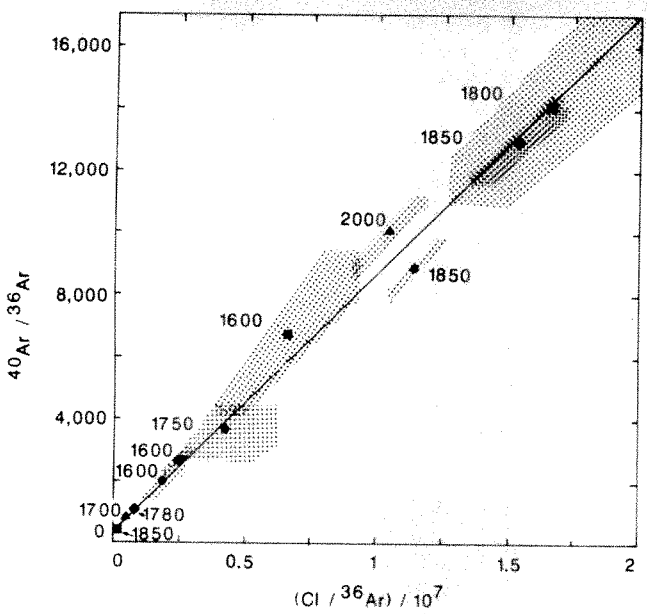

Fig. 3 $^{40}Ar/^{36}Ar$ versus $Cl/^{36}Ar$ correlation plot. Symbols are the same as those in Fig. 1.

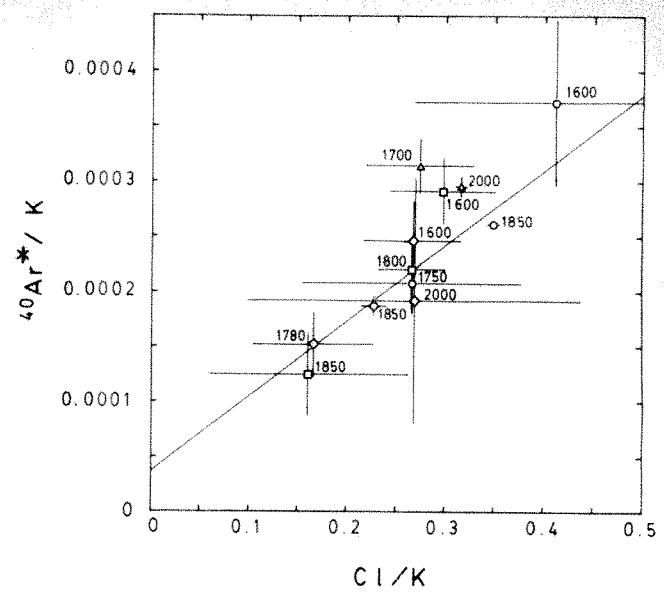

Fig. 4 $^{40}Ar^*/K$ versus Cl/K correlation plot. $^{40}Ar^*$ indicates ^{40}Ar corrected for trapped ^{40}Ar, equal to $340\times{}^{36}Ar$ (the factor 340 is determined from the y-intercept of the line in Fig. 3). Symbols are the same as those in Fig. 1, but are open rather than filled (for clarity).

If the cores crystallized at the deeper region in the mantle and were then transported to the upper mantle where they then developed the coat, the two generations of the noble gas would reflect the respective mantle regions. In fact, such a scenario fits quite nicely the suggestions regarding the noble-gas state in the mantle proposed by many authors[11-14]; whereas the degassed mantle is characterized by a high $^{40}Ar/^{36}Ar$ ratio and thereby a high abundance of ^{40}Ar relative to other noble gases, the less degassed deeper mantle retains the primordial noble gases. The argon that is correlated with potassium and chlorine has a very high $^{40}Ar/^{36}Ar$ ratio, similar to those commonly observed in mid-ocean-ridge basalts and in contrast to the relatively low $^{40}Ar/^{36}Ar$ ratio in the uncorrelated argon (Fig. 2). The latter may correspond to the lower-mantle component. A solar-type neon found in the core of Zaire cubic diamonds[8] thus would also represent the deeper mantle.

The ^{40}Ar–^{39}Ar technique can be used to provide additional chemical information in the form of Ca concentrations, by way of the reaction $^{40}Ca(n,\alpha)^{37}Ar$, and Cl concentrations, by way of the reaction $^{37}Cl(n,\gamma,e^-)^{38}Ar$. Abundances of K, Ca and Cl have been calculated from ^{39}Ar, ^{37}Ar and ^{38}Ar after the usual interference corrections plus a correction for trapped ^{38}Ar (equal to 19% of the measured ^{36}Ar). Bulk element abundances for the four samples analysed, based on a summation of the temperature steps, are given in Table 2. The absolute abundances in the table are probably not particularly significant, in view of the observations by Navon *et al.*[4] that Ca, K and a number of other elements are concentrated, along with H_2O and CO_2, in sub-micrometre inclusions. If the diamonds that we have analysed contain inclusions similar to those observed by Navon *et al.*, we must conclude that the Cl abundances are also extremely high, possibly as much as 1.2–6 wt%.

Table 2 Argon and element abundances

Sample	^{36}Ar (10^{-9} cm^3 STP g^{-1})	^{40}Ar (10^{-9} cm^3 STP g^{-1})	K (p.p.m.)	Cl (p.p.m.)	Ca (p.p.m.)
87N01	0.750	3,423	18.8	5.32	ND
88N01	0.435	2,390	15.0	4.62	5.44
88N02	0.434	2,354	17.4	4.18	12.33
88N03	0.500	2,994	26.0	5.41	1.97

K, Cl and Ca were calculated from ^{39}Ar, ^{38}Ar and ^{37}Ar. The conversion factors for these element abundances are based on measurements of $^{37}Ar/^{39}Ar$, $^{38}Ar/^{39}Ar$ and the J value (from $^{40}Ar/^{39}Ar$) in the monitor MMHb-1, combined with the Ca and Cl abundances determined for MMHb-1 by Roddick[17]. Using the notation of Kelley *et al.*[18], we obtain a production rate of Ar from Ca, relative to the rate from K, of $\alpha = 0.472$, and from Cl, relative to K, of $\beta = 12.2$.

In Fig. 3, $^{40}Ar/^{36}Ar$ is plotted against $Cl/^{36}Ar$. The correlation is excellent and indeed seems superior to the correlation with $K/^{36}Ar$. Figure 3 can be interpreted as a mixing diagram between a component with a low $^{40}Ar/^{36}Ar$ ratio (equal to 340 ± 80 based on the intercept of Fig. 3) and a chlorine-correlated excess ^{40}Ar component with a molar $^{40}Ar/Cl$ ratio of $(8.4\pm0.7)\times10^{-4}$. The situation is analogous to that described in ref. 9 for shallow hydrothermal fluids which have leached Cl and ^{40}Ar from crustal rocks. It is remarkable but not unduly surprising that a similar correlation is found in fluids that we presume to originate in the upper mantle.

Because K/Cl is not constant but shows a factor of two variation (Table 2), $^{40}Ar/^{36}Ar$ cannot correlate perfectly with both $K/^{36}Ar$ and $Cl/^{36}Ar$, and we may therefore investigate whether or not it is possible to separate K-correlated (*in situ* radiogenic?) argon from Cl-correlated (excess?) argon. An attempt to do this is shown in Fig. 4, which is a graph of $^{40}Ar^*/K$ against Cl/K. $^{40}Ar^*$ is the measured ^{40}Ar minus a correction of $340\times{}^{36}Ar$ for the component represented by the intercept of Fig. 3. Because of the high $^{40}Ar/^{36}Ar$ ratios the correction is very small. In spite of the large error bars arising from the small amounts of gas involved, there appears to be a well defined trend in Fig. 4 by which high $^{40}Ar^*/K$ ratios (and correspondingly high apparent K–Ar ages) correlate with high Cl/K. The most straightforward interpretation of the correlation is that it represents a mixture of (predominantly) radiogenic argon in a K-rich phase, $Cl/K\leq0.15$, with (predominantly) excess argon in a Cl-rich phase, $Cl/K\geq0.4$. Under this interpretation, the most meaningful K–Ar age estimate is obtained from $^{40}Ar^*/K$ for the K-rich endmember. It is not possible to determine this ratio with any accuracy from Fig. 4. The best-fit straight line suggests an age between zero and 3.0 Gyr. Although this age is imprecise, it is comfortably less than the age of the Earth.

The data by Navon *et al.*[4] gives a C/K ratio (atomic) of ~9. The Zaire cubic diamonds show fairly constant ratios of $K/^{40}Ar$ (this study and ref. 1) and $^4He/^{40}Ar$ (O.Z. and S.Z., unpublished data), which are 3×10^3 and 0.8 respectively. The $^3He/^4He$ ratios in the Zaire cubic diamonds are in the range $(4.2\text{–}13)\times10^{-6}$ (ref. 8). Hence, we estimate the value of $C/^3He$ in the inclusions

to be $\sim 5 \times 10^9$. This is close to the value of 2×10^9 characteristic of the upper mantle[15,16], thereby suggesting a common occurrence of the fluids in the mantle.

Conclusions

To summarize, we conclude the following. (1) ^{40}Ar-^{39}Ar step-heating dating of four cubic diamonds from Zaire gives an apparent age of 5.7 Gyr, which is close to the K–Ar isochron age obtained earlier[1]. (2) There is excellent correlation of ^{40}Ar with Cl and K in the cubic diamonds (Figs 1 and 3), and thermal-release patterns for ^{40}Ar, K(^{39}Ar) and Cl(^{38}Ar) are almost identical (Fig. 2). These results show that the ^{40}Ar was trapped with K and Cl, most probably as fluid inclusions. Hence, the extraordinary K–Ar age observed for the Zaire cubic diamonds is attributed to the presence of excess ^{40}Ar. The fluid inclusions are likely to correspond to the micro-inclusions observed by Navon *et al.*[4] for several cubic diamonds, including two from Zaire. (3) Most of the other noble gases (Ne, ^{36}Ar, Kr, Xe) reside in different sites to that of ^{40}Ar. These two distinct noble-gases sites can be best explained on the basis of a two-stage growth model for cubic diamonds as proposed by Boyd *et al.*[5]. This model suggests that whereas most of the ^{36}Ar and other noble gases were trapped in the core of cubic diamonds, ^{40}Ar was trapped later as fluid inclusions in the coat of the diamonds in the upper mantle. The solar-like Ne (ref. 8) and the Ar with low $^{40}Ar/^{36}Ar$ ratios, which reside in the core, then represent the mantle region where the core of the diamonds crystallized, which is possibly the deeper mantle.

We thank Drs M. H. Dodson and D. Mattey for helpful reviews. The research was supported by the Japanese Ministry of Education. We are grateful to Mr K. Nishimura for cathodoluminescence analyses.

Ribulose-bisphosphate carboxylase catalyses the key carboxylation reaction of photosynthetic carbon fixation, but also the competing oxygenase reaction of photorespiration. The structure of the active site of ribulose-bisphosphate carboxylase described here should provide a rational basis for attempts to improve the efficiency of the enzyme by genetic engineering.

RUBISCO (ribulose-1,5-bisphosphate carboxylase/oxygenase) is an important target for protein engineering as it controls two competing physiological functions in green plants[1]. The enzyme catalyses the carboxylation step in the Calvin cycle of carbon dioxide fixation, a process that stores the energy trapped by photosynthesis. Rubisco also catalyses the initial oxygenation step in photorespiration, during which a considerable amount of the stored energy is converted to heat thereby limiting crop yield. Detailed knowledge of these catalytic mechanisms as well as the structure of the active site is a prerequisite for rational attempts to modify Rubisco by site-directed mutagenesis to increase the carboxylation/oxygenation ratio.

Both catalytic activities of Rubisco require an activation process during which a lysine residue reacts with an activator CO_2 molecule[2,3]. The labile carbamate formed in this reaction is stabilized by a magnesium ion[4]. The substrate ribulose-1,5-bisphosphate binds to the activated ternary complex and is subsequently either carboxylated by CO_2 or oxygenated by O_2. All biochemical evidence indicates that these two reactions occur at the same site in the protein[1].

We have previously described[5] the folding of the polypeptide backbone of non-activated Rubisco from the photosynthetic bacterium *Rhodospirillum rubrum*. This molecule is a dimer of two identical L-chains, each of relative molecular mass (M_r) 55,000 (55 K), which show about 30% amino-acid sequence identity with the L-chains of Rubisco from higher plants[6]. Almost all side chains are now positioned in this model which has been refined at a resolution of 2.3 Å. Here, we describe the active site of this model as well as the binding mode of phosphoglycerate, which is a product in the catalytic reactions.

Rubisco molecules from higher plants consist of eight L-chains and in addition eight small polypeptide chains, S, (M_r 15K) of unknown function forming an L_8S_8 enzyme molecule. A model, based on X-ray studies, for the arrangement of the subunits in the non-activated form of the enzyme from tobacco has recently been published[7]. We describe here the X-ray structure of the activated form of Rubisco from spinach with a bound transition state analogue, 2-carboxy-D-arabinitol-1,5-bisphosphate (CABP). In addition, we describe the mode of binding of CABP and the active-site metal atom as well as the effector CO_2 molecule and compare the active sites of the non-activated and activated Rubisco molecules.

Structure determination

Rubisco from *Rh. Rubrum*. X-ray data to 1.7 Å resolution of crystals[8] of the non-activated form of *Rh. rubrum* Rubisco were collected on 1° oscillation photographs using the wiggler beam line at the synchrotron radiation source in Daresbury, UK. These

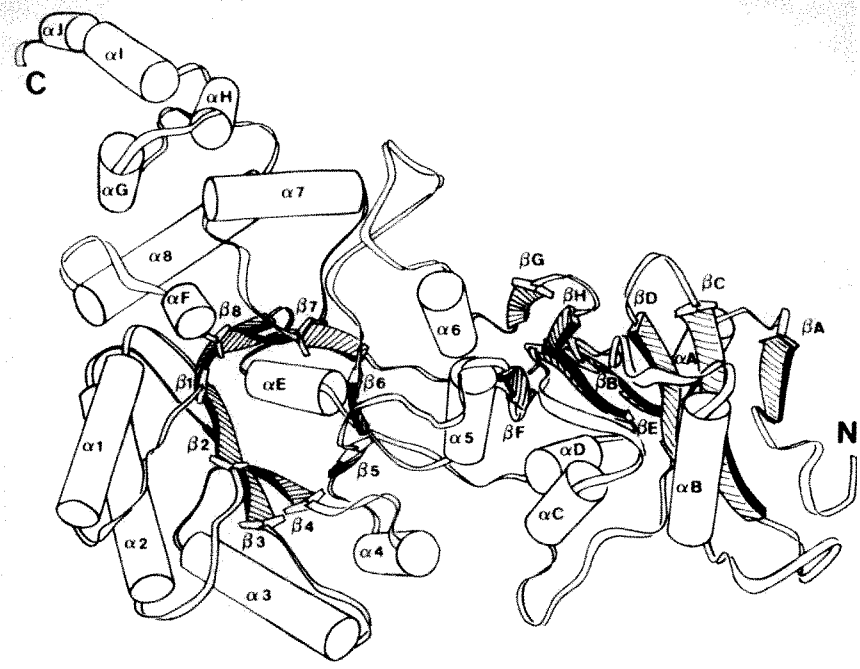

Fig. 1 Schematic view of the large subunit of Rubisco from *Rh. rubrum*. β-strands are represented as striped arrows and α-helices as cylinders. The N-terminal domain comprises residues 1–137 and contains β strands βA–βE, which form a mixed five-stranded β-sheet. Helix A is on one side of the β-sheet, and helices B and C are on the other side of the sheet. A region of extended chain after helix D makes the connection to the C-terminal domain. The C-terminal domain has an α/β barrel structure comprising eight parallel β-strands, β1 to β8, and eight α-helices, α1 to α8 outside the barrel formed by the β-strands. After helix E which closes off the barrel on one side, the chain enters β-strand 1 of the α/β-barrel motif. This domain contains some additional secondary structural features. After helix 6, the polypeptide forms a loop with two antiparallel β-strands (G and H), before the chain enters strand 7 of the α/β barrel. Furthermore, in the loop between β8 and α8 there is a short helix (F), which is not part of the barrel motif. After the barrel motif has been completed the polypeptide chain forms helices G–J at the C terminus. These secondary structure elements are assigned to the corresponding amino-acid sequence numbers for Rubisco from *Rh. rubrum* in Table 2. (Drawing by Ulla Uhlin.)

data were used to refine the initial Rubisco model[5] by the methods of least-squares[9,10] and computer graphics modelling[11]. The crystallographic R-factor decreased from 38.6% at 2.9 Å resolution for the starting model to 21.0% at 2.3 Å resolution for the current model.

Native crystals were soaked with 3-phosphoglycerate and a data set was collected to 2.9 Å resolution on a four-circle diffractometer. The positions of bound 3-phosphoglycerate were determined from a difference Fourier map and the structure of the complex has been refined to an R-value of 19.6%.

Spinach Rubisco. Crystals of activated enzyme which was cocrystallized with the transition state analogue, CABP, were prepared as previously described[12]. Data collection procedures and phasing statistics are presented in Table 1. The L_8S_8 molecule is centered at $x = 0$, $y = 1/4$ and $z = 1/4$ in space group $C222_1$ with a crystallographic twofold axis relating the asymmetric halves of the molecule. The molecule has approximate 422 symmetry as a non-crystallographic fourfold symmetry axis passes through this centre and is inclined at 2.0° to the c-axis in the (101) plane. An envelope of the molecule was defined from an isomorphous, solvent-flattened[13] map, calculated using heavy atom positions located by Pattersson search methods which included the local fourfold symmetry. A final electron density map to 2.8 Å resolution was obtained from phase angles refined by real space averaging[14] of the isomorphous map around the fourfold axis.

A model of the spinach L-chain could easily be built[11] into this map, starting from the *Rh. rubrum* Rubisco structure. The map shows clear density for the activator CO_2 as well as for the transition state analogue, CABP. The metal atom position was located from a difference Fourier map of the cobalt-substituted enzyme.

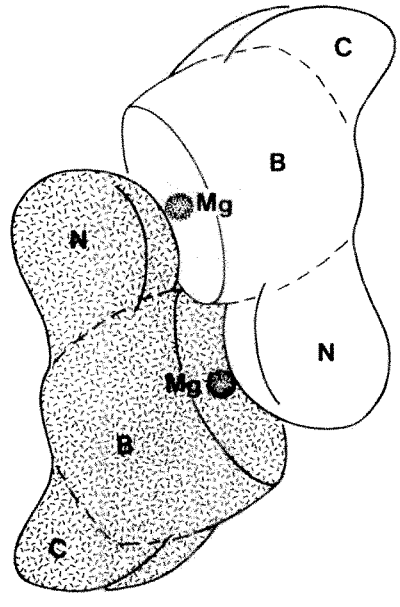

Fig. 2 A schematic diagram of the L_2 Rubisco dimer illustrating that the core of the dimer interface is formed by interactions between the C-terminal domains of both subunits. In addition the N-terminal domain of one subunit interacts with the C-terminal domain of the second subunit in the vicinity of the active sites. (Drawing by Ulla Uhlin.)

Formation of L_8S_8 Rubisco molecules

The subunit structure of the L-chain in L_8S_8 Rubisco from spinach is fairly similar to that of L_2 Rubisco from *Rh. rubrum*. It is divided into two domains, one smaller N-terminal domain linked to a C-terminal domain which has an eight-stranded α/β barrel structure. The domain arrangement in the subunit and the secondary structure of these domains are illustrated in Fig. 1. The amino-acid residues that form the secondary structure elements in the well defined Rubisco subunit from *Rh. rubrum* are given in Table 2.

Two subunits interact tightly to form the functional L_2 dimeric Rubisco molecule of *Rh. rubrum* (Fig. 2). The core of this binding area consists of interactions between the two C-terminal domains around a local twofold axis. In addition, two regions from the N-terminal domain of one subunit interact with regions from the C-terminal domain of the second subunit. These subunit interactions are of functional importance as some of the residues involved occur in or close to the active-site region.

Each active site of the L_2 dimer is thus built up from residues of both subunits. It is therefore not surprising that similar L_2 dimers occur as part of the L_8S_8 Rubisco molecule from spinach as well as tobacco[7] and build up the functional active sites. In the spinach enzyme four such dimers are arranged around the local fourfold axis, building up the L_8 core of the molecule. There are large crevices between the ends of the L_2 dimers at the top and the bottom of the L_8 core. The S-subunits occupy these crevices. The overall shape of the molecule resembles a cylinder with a diameter of approximately 110 Å and height 100 Å. The eight active sites are on the outside of the molecule

Crystals of spinach Rubisco are orthorhombic, space group $C222_1$ with cell dimensions $a = 157.2$ Å, $b = 157.2$ Å and $c = 201.3$ Å. X-ray data were collected on 1° oscillation photographs using synchrotron X-ray sources. Data at 0.87 Å wavelength were obtained from a wiggler beamline. All crystals used were screened for the absence of twinning before use. The data were processed and scaled using the programmes OSC and PROTEIN, kindly provided by J. Remington and W. Steigeman, respectively, and modified by T. A. Jones. Strongly occupied heavy-atom positions were located from difference Pattersson maps using an automated search programme written by one of us (S.K.) which searched both Harker and cross-vectors using the non crystallographic fourfold symmetry of our crystals. The remaining sites were located from difference Fourier maps. For the refinement, 28 positions were used for the Hg derivatives and 12 for the Au derivative. * DESY, The European Molecular Biology Outstation facilities at the Deutsches Electronen Synchrotron, Hamburg; SRS, Synchrotron Radiation Source in Daresbury, UK. facing the solution. They are spaced widely apart; the shortest distance between the active-site metal atoms is 36 Å. The S-subunits are far from the active sites. There is no contribution to the active site of residues from the S-subunits.

The active site

The active site in the spinach enzyme was identified from the position of the bound transition-state analogue, CABP, as well as the active-site metal atom. The site is shaped like a funnel and is mainly formed by the eight loop regions that connect the eight β-strands with the corresponding helices in the α/β barrel domain. The amino-acid sequences of these loop regions are listed in Table 3 for both *Rh. rubrum* and spinach Rubisco. The N-terminal domain of the second subunit covers part of the top of the active site. In particular, two loop regions of this domain provide residues to the active site. Their sequences are also listed in Table 3.

There is an unusually large number of charged and polar groups in the active site. Within a distance of 10 Å from the active-site metal ion there are four positively charged (Arg and Lys) and four histidine side chains, four negatively charged (Asp and Glu) and 10 other polar side chains which build up one active site region. All the charged side chains as well as the histidines are conserved in all known species of Rubisco. These residues are boxed in Table 3. All of them except one, Glu 48/60, (the first number refers to the *Rh. rubrum* sequence and the second number to the spinach enzyme) are located in the α/β domain.

The position of the active-site metal atom could be accurately determined from the cobalt-substituted spinach enzyme. It is situated in the middle of the active site close to its bottom and is shielded from solution by CABP. Activator CO_2 at the end of the side chain of carbamylated Lys 191/201 forms one of the protein ligands to the metal (Figs 3 and 4). Substrate CO_2 simulated by the carboxyl group of CABP forms a second ligand. In addition, the side chain of Asp 193/203 as well as the hydroxyl group attached to C2 of CABP (Fig. 4) are close enough to the metal to be ligands. A third invariant residue in loop 2 of the

The labelling of the secondary structure elements is as follows: β-strands and α-helices are labelled in alphabetical order starting from the N terminus except those secondary structure elements which build up the α/β barrel in the C-terminal domain. These eight β-strands and α-helices are numbered β1–β8 and α1–α8. The secondary structure elements were assigned using the algorithm of Kabsch and Sander[28].

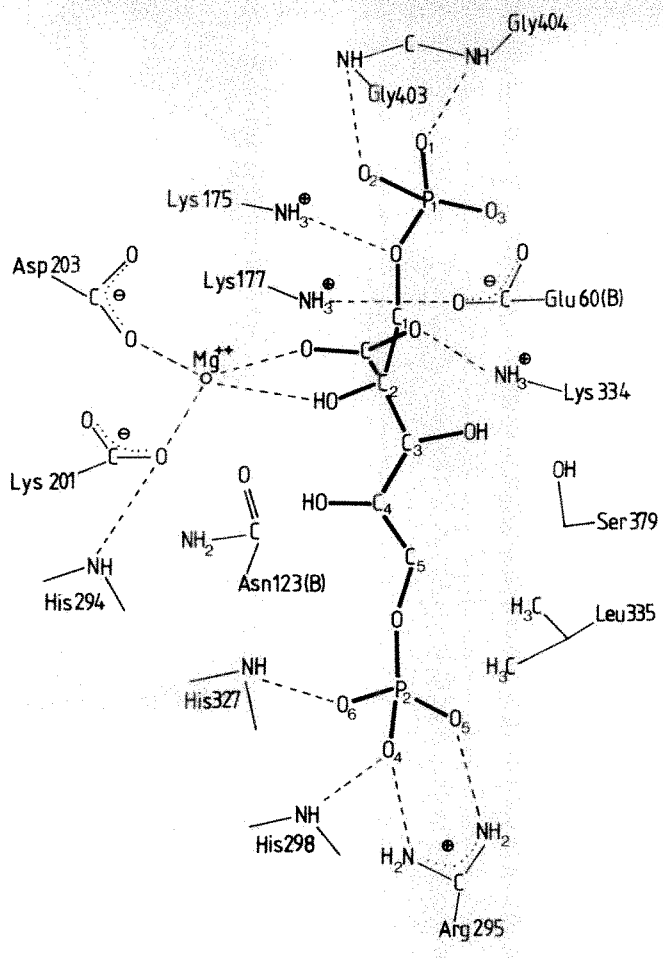

Fig. 3 Schematic diagram of interactions between protein side chains and the metal atom of activated spinach Rubiso as well as a bound transition state analogue, CABP (2-carboxy-D-arabinitol-1,5-bisphosphate).

barrel domain, Glu 194/204, can be model built to ligand the metal through its carboxyl group. The electron density, however, is very weak in our map for this side chain. The invariant residue Asn 111/123 from loop B of the N-terminal domain of the second subunit is also close to the metal atom but too far away (3.5 Å) for strong coordination to the metal atom in our current model.

CABP binds in a rather extended conformation across the barrel (Fig. 4). There are two distinct phosphate-binding sites at opposite sides of the funnel, separating the two phosphorous atoms of CABP by a distance of 9.7 Å. One phosphate-binding site is formed mainly by the adjacent loops 1 and 8 (Table 3). We shall refer to this as phosphate-binding site I. There are two positive charges in the vicinity of the phosphate group, Lys 166/175 and Lys 329/334. In addition two of the phosphate oxygen atoms can form hydrogen bonds to the main chain NH groups of Gly 393/403 and Gly 394/404. These residues are at the N terminus of a short helix in loop 8. Loops 5 and 6 (Table 3) provide the second phosphate binding site II. The side chains of Arg 288/295, His 291/298 and His 321/327 are within 4 Å to oxygen atoms of this phosphate group and surround it with positive charges (Figs 3 and 4).

The sugar bisphosphate molecule is thus anchored at its two ends on opposite sides of the funnel by the phosphate-binding sites and oriented in the middle region by coordination to the active-site metal. In addition the C-4 hydroxyl group interacts with Asn 111/123 from the other subunit (Fig. 4) and the C-3 hydroxyl is close to the invariant residue Ser 368/379. Furthermore, the positively charged groups Lys 166/175 and Lys 329/334 are within interaction distance to the carboxyl group of CABP (Fig. 4) as well as to the phosphate group P1.

We have also studied the binding of the product, phosphoglycerate, to the nonactivated form of the enzyme from *Rh. rubrum*. We find that one molecule of phosphoglycerate binds per active site. When the active site with bound phosphoglycerate is superimposed on the active site of the spinach enzyme with bound CABP we find that the phosphate group of phosphoglycerate binds to phosphate binding site II. Arg 288/295 and His 321/327 provide the positive charges for this binding. The carboxyl group of phosphoglycerate occupies a position close to the position of the metal ion in the activated spinach enzyme. It interacts with the positive side chain of non-carbamylated Lys 191/201. In addition, the asparagine residue from the N-terminal domain Asn 111/123 is also close to the carboxyl group.

The top two lines of each loop refer to the amino-acid sequence of the spinach enzyme with corresponding residue numbers and the bottom two lines refer to the sequence of the enzyme from *Rh. rubrum*. The numbers of the last residue of the β-strands and the first residue of the α-helices are given. Conserved residues are boxed.

Discussion

The structures described here provide new information on the activation process of Rubisco as well as the identification of a number of specific amino-acid residues in the active site of this enzyme. They also show indirectly that the active-site metal atom is crucial in orienting the substrate molecules for a proper catalytic reaction. Together with biochemical and mutant experiments it can be inferred from this that the metal atom probably also has a more direct role in catalysis by polarizing bonds in reaction intermediates.

Activation is required to form the proper metal-binding site. In the non-activated form Lys 191/201 carries a positive charge and participates in forming a binding site for negatively charged groups as shown in phosphoglycerate binding to the non-activated *Rh. rubrum* enzyme. During the activation process this lysine residue is carbamylated by CO_2 and converted to a negatively charged side chain. The binding site is thereby changed so that it can now accommodate a positively charged metal ion which forms a direct bond to the activator CO_2 group. By binding magnesium, the active site becomes poised to properly bind and orient the substrate molecules for catalysis. At least in the six-carbon reaction intermediate, for which CABP is an analogue, this is achieved by direct binding, both to one of the hydroxyl groups of the sugar bisphosphate and to the substrate CO_2 group.

This latter conclusion is strongly dependent on correct interpretation of the electron density for CABP. The structural model agrees on this point with electron paramagnetic resonance data[15,16] which are consistent with metal binding to both these groups. The orientation of CABP in our model also agrees well with the stereochemistry of the catalytic reaction[17] and with NMR measurements on the relative distances between the metal atom and the phosphorous atoms. In our model the distance from the metal to P2 is 7.8 Å and to P1 6.6 Å. The ratio of these distances, 1.2, is in good agreement with NMR measurements[18]. Furthermore, by making similar NMR measurements on CABP labelled separately on P1 and P2 with ^{17}O it has been shown[19] that P1 is closer to the metal atom than P2.

Several mutants of the metal ligands have been constructed using the *Rh. rubrum* gene to study the functional role of magnesium and its ligands both in the overall reaction and in partial reactions[20]. The results of these studies can now be correlated to the structure of the active site.

To determine whether the charge or the length of the lysine side chain is the important feature of the activation process Lys 191/201 was changed[21] to Glu. The mutant was completely inactive and could not form a stable complex with CABP. Model building shows that Glu is too short to form a proper metal-binding site instead of carbamylated Lys.

Mutation of the metal ligand Asp 193/203 in *Rh. rubrum* to Asn abolishes the carboxylation reaction[20]. At high concentrations of magnesium however, the mutant catalyses formation of product when presented with the six-carbon reaction intermediate (2'carboxy-3-keto-D-arabinitol 1,5-bisphosphate). It did not, however, catalyse an earlier step in the reaction sequence, enolization of the substrate ribulose 1,5-bisphosphate. This early step, which is essential for CO_2 addition and which involves abstraction of a proton from C3 of the substrate thus requires an intact metal-binding site. Enzymatic studies of Rubisco where magnesium has been substituted with different metals have also shown that the nature of the metal strongly influences partitioning between carboxylation and oxygenation[22].

Mutants where the adjacent residue Glu 194/204 has been changed to Gln or Val did not catalyse overall carboxylation, nor the partial enolization reaction or product formation from the reaction intermediate[20]. Clearly this residue has an important function, possibly as a metal ligand.

Identification of the base responsible for the proton abstraction in the enolization reaction has prompted a number of mutant as well as biochemical experiments. Modification of Lys 166/175 by affinity labelling[23] as well as mutations[24] abolishes or drastically decreases catalysis of the enolization reaction. It has therefore been concluded[25,26] that Lys 166/175 is the base responsible for proton abstraction in this partial reaction. In our spinach Rubisco model, which simulates a later stage in the reaction sequence, the nitrogen atom of this side chain is not close to C3 of CABP but instead interacts with the P1 phosphate group and the carboxyl group (Fig. 4). Model building outside the electron density could bring the nitrogen atom within 3 Å from C3. There are, however, four other side chains in our model which are close to C3 of CABP and are also possible candidates for proton abstraction; His 321/327, Lys 329/334, Ser 368/379 and the nitrogen atom of the carbamate group at Lys 191/201.

Glu 48/60 is part of an invariant sequence in loop A of the N-terminal domain. In both structures this residue is involved in subunit interactions with Lys 168/177 from the C-terminal domain of the other subunit (Figs 3 and 4). Mutation of this residue abolishes or drastically reduces activity[27], presumably due to changes in the subunit interactions which could influence the position of Asn 111/123 from loop B of the N-terminal domain which is close to the metal. The active site would no longer be intact and catalysis would be affected.

We thank the staff at the Daresbury synchrotron radiation facility, UK for assistance with the data collection. This work was supported by grants from the Swedish research councils NFR and SJFR.

The combination of high X-ray luminosity[1] (~10^{38} erg s^{-1}), short orbital period[2] (4.8 hours), large non-thermal radio outbursts[3–5] and reports of very-high-energy (up to 10^{15} eV) γ-ray emission[6,7] (see also ref. 8) and muon-rich showers[9–11] makes Cyg X-3 a unique object among X-ray binaries. Very-high-resolution spatial mapping shows that the radio source starts expanding at the beginning of outbursts and becomes elongated[4,5,12], indicating that Cyg X-3 contains a relativistic jet, similar to SS433 (ref. 13). We report here the discovery of a weak (~4.5 mJy), arcsecond-scale double radio source located symmetrically with respect to the compact variable radio core of Cyg X-3. The double radio source has a separation of about 6 arcsec and is roughly aligned with the elongation direction of the sub-arcsec core from Very-Long-Baseline Interferometry observations[12,14,15]. Like the latter it has a rather broad opening angle. This suggests a generic connection between the inner and outer radio structures, and implies that the (poor) collimation evident in the large-scale double source originates near the binary system.

The observations described here were carried out on 14 October 1987 using the Westerbork Synthesis Radio Telescope at 4,874 MHz (6 cm) with an 80-MHz bandwidth, providing an r.m.s. noise level of 0.08 mJy after 12 hours. We did the measurements in standard synthesis mode[16] as part of a long-term study of the variability of the source. In view of this variability (see Fig. 1), we have taken special steps to obtain a map with the required dynamic range. Standard redundancy self-calibration[1] and phase alignment using the unresolved central source enabled us to obtain a dynamic range in the final map (referred to the strength of the central source) in excess of 30 dB. To remove the central component and its near-in sidelobes, we have subtracted a point source from the map at the known position of Cyg X-3 using the flux density given by the measured light curve

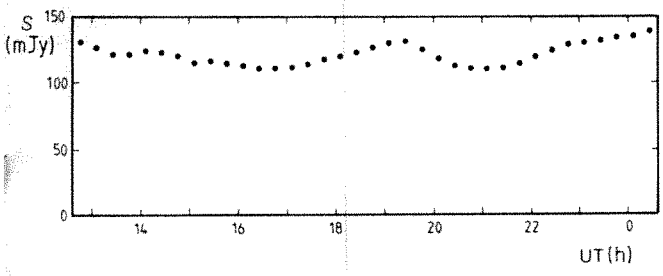

Fig. 1 The 6-cm flux density of the central core of Cygnus X-3 shown as a function of time (UT) on 14 October 1987. Each data point is an average over 20 minutes.

Because our angular resolution is only just sufficient to separate the outer emission from the intense core, there is some uncertainty in the exact level of the central extended emission which underlies the core, and also in the total flux density quoted below. Two other long observations from the present series, of 11 and 9 hours, reproduce the faint double-lobe structure and provide an independent check upon the reliability of our map. The extended structure surrounding Cyg X-3 is shown in Fig. 2. The dominant central component (indicated by a cross) straddles a symmetrical double source with a separation of ~6 arcsec. The axis of this double structure is elongated approximately north-south. The opening angle of the components, when seen from the central source, is about 75°. Despite its low flux density (4.5 mJy in total, split roughly equally between the two components), there is little doubt that the outer double is part of Cyg X-3; its morphology and near-perfect alignment with the central component, and the north-south elongation of the central component on sub-arcsec scales[12,14,15], make the association virtually certain.

For a distance of 12 kpc (ref. 1) we can use the observed angular size, component dimensions and flux densities to derive physical parameters for the Cyg X-3 outer double. To compute the source volume, each component has been approximated by a cone of base diameter 0.4 pc and apex height 0.2 pc. Because of their near-equal flux densities and sizes, we take the components to be alike in all respects and give values only for the entire source. We do not know the spectral index α (defined by the flux density (S)-frequency (ν) relationship $S_\nu \propto \nu^\alpha$) of the double source, but we will assume that the spectrum is non-thermal and hence that the emission is incoherent synchrotron radiation. If we take for α values in the range from −0.5 to −1.1, as observed for the lobes of Sco X-1 (ref. 18) and similar

Table 1 Observed and derived radio-source properties

	Cyg X-3	Sco X-1	SS433
Distance (kpc)	12	0.5	5
S_6, extended emission (mJy)	4.5*	17	100
Size, extended emission (pc)	0.35	0.38	0.12
E_{min}, outer components (erg)	10^{45}	8×10^{40}	10^{43}
B_{eq}, outer components (G)	3×10^{-4}	5×10^{-3}	10^{-3}

* Based on assumed flux densities of 7.6 Jy for 3C147 and of 7.4 Jy for 3C286.

to values found in extragalactic non-thermal radio sources, we find that the minimum energy[19] varies from 0.6×10^{45} to 1.7×10^{45} erg. The parameter values are summarized in the first column of Table 1 (where we assume $\alpha = -0.8$). The extended structures of Cyg X-3 and Sco X-1 are similar not only in their double morphology but also in overall linear size, although the other physical parameters are quite different (Table 1).

Apart from its double structure, the most striking morphological feature of Cyg X-3 is the large lateral extent of the outer emission, which contrasts strongly with Sco X-1 (ref. 20). If the radio lobes are the result of beamed energy transport from the central binary system, then their breadth could be ascribed either to a beam that often changes direction (as is actually observed in the compact radio component of SS433 (ref. 13)) or to one that is intrinsically broad. Observational evidence from Very-Long-Baseline Interferometry (VLBI) investigations is somewhat ambiguous, however. Recent measurements[12] of a low-level flare suggest that the inner sub-arcsec structure, which is directed north-south, has a very large opening angle of ~80°. Although observed on a scale some 5,000 times smaller than the outer components, the VLBI structure subtends essentially the same angle (as indicated schematically in Fig. 2). This would appear to suggest that collimation rather than beam wobble is the cause of the outer components' breadth. VLBI maps made during major outbursts, on the other hand, favour the alternative point of view. Studies of flares observed in October 1983 reveal well-collimated double structures, one[14] elongated in position angle 33° (within but not far from the boundary of the opening angle shown in Fig. 2), and another[15] directed north-south. Thus, although there is evidence for a low degree of collimation during some flare events (to the present time, those of low intensity), beam wobble is observed in well-collimated (and thus far major) outbursts. What is clear is that all of the VLBI structures observed so far are contained within the opening angle defined by the outer components shown in Fig. 2.

In Cyg X-3, as in Sco X-1 and SS433, most of the power is radiated at high (optical and X-ray) frequencies by predominantly thermal emission processes close (10^{11}–10^{12} cm) to the binary system. Although the radio emission is energetically insignificant, only the VLBI components (on a scale of 10^{14}–10^{15} cm) exhibit a morphological link to the outer radio lobes, and we argue that the two structures can be tied together on the basis of a twin-jet model, as has been done for SS433 (ref. 13). We will use the observed and inferred properties of the inner and outer radio emission to investigate the timescale required to generate the outer lobes. The 'quiescent' (slowly varying) emission from the centre of Cyg X-3 has a typical flux density of 200 mJy at frequencies ranging up to 20 GHz (ref. 21). About twice a year[22] there are major (10 Jy or more) outbursts lasting for a few days. The total power output from both

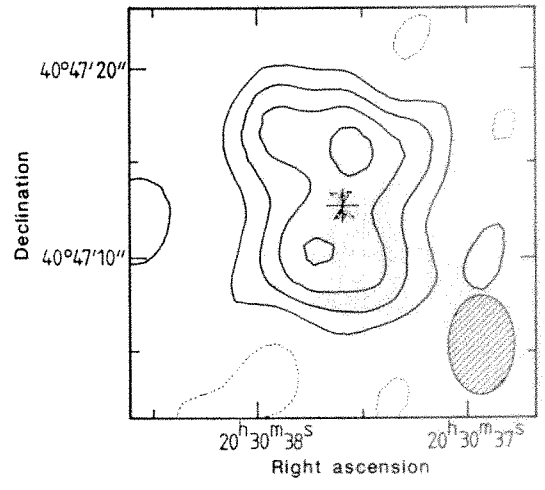

Fig. 2 The extended emission surrounding Cygnus X-3 observed at 6 cm. Contours have been drawn at ±0.21, 0.42, 0.63 and 0.84 mJy per beam. The dominant central component (its position indicated by a cross) has been removed from the map using the flux densities shown in Fig. 1. The hour-glass-shaped shaded region in the centre shows schematically the opening angle of the VLBI components whose true scale is some 5,000 times smaller than the extended structure. The 3.5″ × 5.3″ half-power beam is shown hatched in the lower right-hand corner.

processes (in which the former dominates), P, is $\sim 3 \times 10^{33}$ erg s^{-1}. If a similar amount of power drives the outer lobes then the timescale implied is $E_{min}/P = 11{,}000$ yr (where radiation losses have been ignored, a point we consider below). The corresponding average recession speed of the lobes is nearly 20 km s^{-1}. Although there is no independent evidence as to how energy is shared between the inner and outer radio components, we note that this average speed inferred for Cyg X-3 is similar to that actually measured in one of the lobes of Sco X-1 (ref. 20). The speed at which radio-emitting particles reach the outer lobes may be much higher than this, as implied by the expansion rates of 0.2–0.4c measured using VLBI[14], and by the fact that the components produced by major flares achieve separations of 0.1 arcmin or more after several weeks[14,15].

Radiation losses, which we have ignored in the above estimates, are unlikely to be important provided that the magnetic field strength does not greatly exceed its equipartition value. From standard formulae[19] the lifetime of a synchrotron electron emitting 5-GHz radiation in the equipartition field (Table 1) is 1.4×10^5 yr. This is longer than the age found above, so radiation losses probably do not play a significant role. They do, however, put an upper limit on the age, which could be refined by future determinations of the radio spectrum. Moreover, if the jet efficiency has not changed dramatically with time, Cyg X-3 cannot have been much less active in the past if the outer-component age is to be less than the synchrotron lifetime.

Six of the ten brightest low-mass X-ray binaries (LMXBs) in the Fourth Uhuru Catalogue[23] have been detected as weak radio sources[24]. On the other hand, in a survey of 21 LMXBs by Grindlay and Seaquist[25], only three were detected. These results suggest that radio emission is relatively common in LMXBs but that the radio luminosities vary substantially, a conclusion supported by detailed observations of Sco X-1 (ref. 26), GX13+1 (ref. 27) and GX17+2 (ref. 28). Furthermore, three of the radio-emitting X-ray binaries, Cyg X-3, Sco X-1 and SS433, are now known to have produced extended double radio structures; SS433 also exhibits double-lobed X-ray emission[29]. It is possible that such structures are the rule rather than the exception in LMXB systems, but that they are usually not observed because they are too weak.

The double structure associated with binary systems contrasts strikingly with the morphologies produced and powered by isolated neutron stars. There is no doubt that both the Crab Nebula[30] and the flat spectrum component in CTB80 (refs 31, 32) are maintained by their associated neutron stars/pulsars PSR0531+21 and PSR1951+32, even though their rates of rotational energy loss differ by orders of magnitude. Neither pulsar is in a binary system and both have produced rather amorphous but somewhat elongated synchrotron nebulae. Their structures are quite different from those observed in Sco X-1 and Cyg X-3, a difference which can probably be ascribed to the presence of an accretion disk in the binary systems. Similar arguments are likely to apply to galactic nuclei powering extragalactic double radio sources.

Finally one might wonder why this extended emission was not detected earlier, given that Cyg X-3 has been the subject of intensive scrutiny for over 15 years. One possibility is that, as in Sco X-1 (ref. 20), the outer components vary in intensity. It seems more likely that the extended lobes were not detected previously for instrumental reasons, the major impediment undoubtedly being the strength and variability of the dominant core component. The excellent dynamic range of the Westerbork Telescope was an essential element in our discovery, although the requirements of the present detection (somewhat better than 200:1) are rather modest by the standards of modern synthesis arrays[17]. Our success may derive largely from an angular resolution that happens to be well-matched to the outer lobe dimensions. Unless a significant fraction of the emission in Fig. 2 emanates from sub-arcsecond features, an observation with, say, a 1-arcsec beam would have to reach a noise level of 0.02 mJy and a dynamic range of at least 6,000:1 to obtain a reliable detection. With greater resolution, or when the core is more active or at shorter wavelengths, the demands will be even higher. Variable cores may well be masking similar extended structures in other binary systems.

The Westerbork Synthesis Radio Telescope is operated by the Foundation for Radio Astronomy with financial support from the Netherlands Organisation for Scientific Research (NWO). We are grateful to Dr R. M. Hjellming for several useful suggestions.

Note added in proof: Further analysis of our data suggests that the extended emission is (partially) polarized, establishing its non-thermal nature.

Is PSR1957+20 eclipsed by a comet, magnetosphere or particulate cloud?

F. Curtis Michel

Space Physics and Astronomy, Rice University, PO Box 1892, Houston, Texas 77251, USA

The extraordinary eclipsing binary pulsar PSR1957+20 is in eclipse over eight per cent of its orbit[1]. This is more than twice the extent of the companion's Roche lobe, the maximum stable synchronous configuration. A possible explanation[2] for the large eclipse is that it is caused by a plasma wind driven from the companion and forming a comet-like tail[3]. But an ionized cometary tail implies a refractive eclipse, which would produce large variations in pulse arrival times; this is inconsistent with the small time delays observed. Here we suggest two alternative explanations. One possibility is that the companion has a typical white-dwarf magnetic field ($\sim 10^5$ gauss), and that the eclipse is then due to the plasma-filled magnetosphere which is confined and blown back sharply by the pulsar wind, with the time delays produced by a much less dense tail. In the other limit of negligible magnetization of the companion, an eclipse could be caused by a particulate cloud (comprising particles of size ~10 cm) which should form

about the companion. We assume that the companion is the remnant of an evolved companion star that is now being excited by the 622-Hz pulsar radiation. Such excitation could either supply plasma to the magnetosphere (for the magnetized case) or pull off neutral gas and deposit it in the vicinity to sustain a particulate cloud (for the non-magnetized case). Near-infrared radiation from this variable system might test the cloud hypothesis, whereas time delays in a magnetized tail suggest radio-frequency polarization tests for the magnetosphere model.

PSR1957+20 consists of a 1.6-ms pulsar and a 0.02-$M_\odot$ companion[1]. The eclipse duration (8×10^{10} cm of orbital trajectory for a pulsar mass of 1.4 $M_\odot$ and therefore a separation $a=1.7\times10^{11}$ cm), is more than a factor of two larger than the Roche-lobe distance (L_1 is located at 2.8×10^{10} cm, and the equipotential surface from that point extends $\pm1.9\times10^{10}$ cm along the orbital axis), so the companion apparently cannot be physically large enough to block the pulsar signal (for this mass, the companion's radius is presumably $\sim3\times10^9$ cm (ref. 4)).

The eclipses of PSR1957+20 by its companion seem quite diagnostic, and seem to be real rather than indicating loss of lock with the pulsar owing to increasing time delay (D. Stinebring, personal communication). For zero orbital eccentricity and an eclipse extending from 0.21 to 0.29 of phase (zero phase is the ascending node and unit phase corresponds to a full revolution), to first order, the eclipse is symmetric and centred on inferior conjunction (that is, as if the pulsar were occulted by the body of an orbiting sphere 4×10^{10} cm in radius). This degree of symmetry rules out almost immediately eclipses of the pulsar by a cometary structure around the companion, because, owing to the intrinsic curvature of such cometary tails, the flanks would be intercepted at different distances and phase angles on entry and exit from eclipse. This is indicated in Fig. 1, where we have numerically simulated the cometary shape; a sharp-entry eclipse would obtain, but not a sharp-exit eclipse. This confirms the sketch given in ref. 3.

In the simulation, we assumed a standard outflow wind of 600 km s^{-1} and radial wind acceleration 12 times the local pulsar gravitational acceleration (chosen only to give a roughly correct cross-sectional size). This model is a direct generalization of a standard one for comets, in which, because of the smaller relative scales involved, the solar-wind acceleration is often approximated as uniform and unidirectional. Of course, this refers to individual particle trajectories, but the overall morphology conforms to the obvious expectations. One can imagine effects that would cause the cometary tail to flare more (plasma pressure gradients within the tail, for example, which must be outward), but not less. E. S. Phinney (personal communication) has suggested that the tail might be highly collimated, expanding only to a fixed cross-section, which would lead to shadowing of the tail by the cometary head; however, shadowing of a relativistic wind would surround the tail with a vacuum region, and rather specialized properties would then be required of the tail plasma for it not to expand to fill these regions, that is, for it not be collimated in the first place. More realistic calculations are clearly needed.

There is a measurable time delay of up to at least 400 μs, which trails off over another 15° following the eclipse, but there is essentially no time delay preceding eclipse. Although it is tempting to suppose that this time delay is directly related to propagation through the tail in Fig. 1, it is too small in magnitude to give a sharp eclipse by having this plasma refract the radio pulses away from the observer. Refraction by plasma occurs away from high plasma concentrations and hence permits eclipses, whereas refraction by neutral gas is towards high gas concentration and hence does not completely interrupt the signal; the Voyager spacecraft was tracked continuously behind Uranus, for example (V. R. Eshleman, personal communication), because of the latter effect. Given that the radius of the system is ~5.8 light-seconds, the average index of refraction along a line of sight that reaches to within 4×10^{10} cm of the companion (the impact parameter at eclipse) differs from unity by less than one part in 10^4, which is much too small to give a refractive eclipse. A refractive eclipse may result (without much time delay) only for a very steep gradient in electron concentration. This could indeed be provided by an advancing cometary structure (corresponding to the entry eclipse in Fig. 1), but would not necessarily give exit from the eclipse at precisely the symmetric phase angle, if eclipse was to come from refraction in the tail; furthermore, one would then expect much larger time delays than are observed.

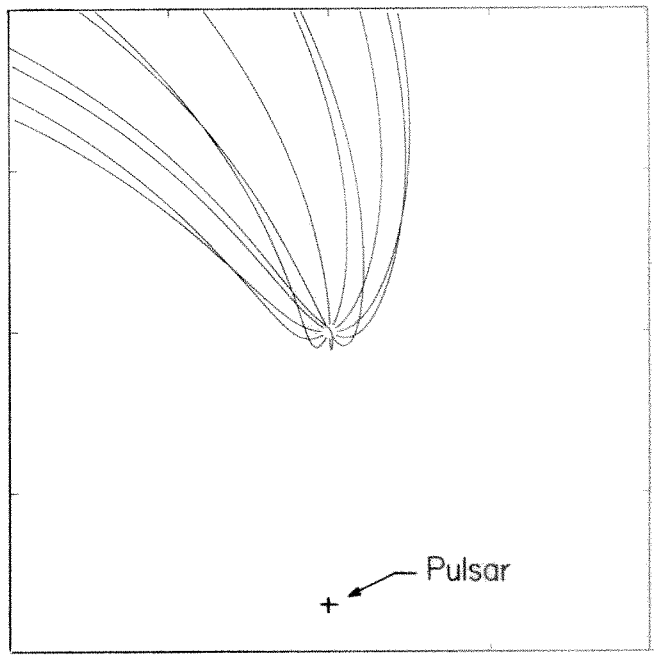

Fig. 1. Simulated cometary wind. Individual particle trajectories are shown in the co-rotating frame, assuming an outflow of 600 km s^{-1} and an outward pulsar-wind acceleration of 12 times the pulsar gravitational attraction (required to give a reasonable scale). Orbital motion is clockwise. Such a system can give a sharp entry eclipse and a sharp refraction exit eclipse, but the exit eclipse would be geometrically unrelated in phase with the entry eclipse, and for refraction to be important the exit eclipse would also have a very large associated time decay. Eclipses are instead observed to be quite symmetric, with only a small time delay.

On the other hand, such eclipses are perfectly consistent with occultation by plasma trapped in an extended magnetosphere. An extended magnetosphere is quite similar in morphology to a comet, with a tight 'nucleus' (the closed field lines) and an extended 'tail' (field lines dragged back by wind interactions). However, the trapped plasma concentration on the closed field lines can be, and usually is, orders of magnitude larger than that on the open field lines, where the plasma is flowing away and being lost. Thus a magnetosphere would present a symmetric occulting object (in contrast to an outflowing cometary flow), and the time delays would be attributable to the small concentrations in the tail (again in contrast to a cometary flow, for which the concentrations in the head cannot be dramatically different from those in the near tail). A significant mass loss does not arise obviously from such a model. The observed maximum column density of 5×10^{16} cm^{-2} is converted to a loss rate by multiplying by some characteristic transverse scale and some characteristic velocity. These are plausibly determined by, respectively, the eclipse size and the escape velocity ($\sim3\times10^7$ cm s^{-1}), which values then give a scale loss rate of 10^{12} g s^{-1}, which is four orders of magnitude smaller than is required for evaporation.

Given that the pulsar-wind field could be 10–30 G at the companion (if $\dot{P}\geq10^{-20}$ s s^{-1}), one needs a comparable field

from the companion at the magnetopause, and hence a surface field of $\sim 10^5$ G, which value is not at all exceptional for white dwarfs. The magnetopause would be about 13 times the size of the companion, which is very nearly the case for the magnetosphere of the Earth and smaller than that of Jupiter.

If the time delay originates in magnetized plasma, there should be a differential time delay that depends on the sign of circular polarization. If the observing frequency (ω) is high compared with cyclotron (ω_c) and plasma (ω_p) frequencies, the time delay $\delta t_\pm$ is

$$\delta t_\pm = \frac{\omega_p^2}{2\omega^2}\frac{L}{c}\left[1 \pm \frac{2\omega_c}{\omega}\right]$$

(where L is the path length), so the difference between left- and right-circular-polarization time-delays is a factor of $4\omega_c/\omega$ of the average time delay ($\sim 400\,\mu$s at 430 MHz). The observed Faraday delay seems to be less than $\sim 2\,\mu$s (D. Stinebring, personal communication), implying that the limiting tail field is ~ 0.2 G.

This value is small compared with that at the magnetopause, whereas one expects that the two should be roughly comparable (within about an order of magnitude). If the magnetic field is inclined relative to the spin axis, however, it is possible that the line of sight is through both lobes of the tail (one with magnetic field away from the companion and the other towards the companion) so that the time delays average out. For the expected radial expansion, these time delays should be established by particles and fields within an orbital radius. Unfortunately the Faraday rotation would be too sensitive a measure of the time delays, giving large rotation measures that would effectively depolarize the radio signal, which is consistent with the observed weak, or possibly non-existent, polarization of the pulsar. Some dependence of frequency on eclipse size would also be expected, being determined by the electron concentration inside the magnetopause.

In the other limit of low magnetization we require a model with characteristics similar to those of Epsilon Aurigae. In ε Aur a cloud of scattering particles is thought to cause occultation, although there are difficult, unresolved questions concerning the particle dynamics, evolution, maintenance and origin. Such questions would also pertain here; however, we have determined numerically that it is at least possible for independent particle ('Kepler') retrograde orbits to exist that extend far enough out from the companion to cause the eclipse. Larger orbits quickly become unstable, suggesting that the size of an occulting cloud may be fixed by orbital stability. One problem common to ε Aur is the requirement for the disk-shaped cloud to be either inclined or thick, as there is a low *a priori* probability of occultation of the pulsar by a thin disk seen edge on. Too thick a disk, however, would obscure optical radiation from the companion. If indeed the companion had no significant magnetic field, the pulsar wind could flow directly onto its photosphere, lighting up the hemisphere facing the pulsar, as observed[5,6]. At the terminator, plasma and entrained gas can be driven away from the companion. The natural consequence would be the formation of a meteor-like trail of ionized gas (which would presumably then produce the time delay) together with a 'fountain' of neutral gas with a wide velocity dispersion. If the companion is indeed the remnant of an evolved star, the vapour-phase fountain will contain some carbon (perhaps predominantly), which is readily condensed and highly refractory. Such a physical system could therefore support an orbiting condensate cloud, with solid particles accreting to significant sizes on each pass of their orbits through the gas fountain. Retrograde orbits are the natural expectation for low-velocity outflow, for which the tail in Fig. 1 is swept back so much that it encircles the companion. Particles several centimetres in size would be required to occult radio signals. About 10^{-10} of the companion's mass, in the form of such particles, would be adequate to cause extinction. If such a disk reprocessed the energy intercepted by the companion, it would constitute a 20th magnitude infrared object at a temperature of $\sim 10^3$ K.

I acknowledge valuable discussions with D. Stinebring, C. R. O'Dell, D. D. Clayton, R. Smalley and A. J. Dessler. This research was supported by the NSF.

Evidence from the Semarkona ordinary chondrite for ^{26}Al heating of small planets

I. D. Hutcheon* & R. Hutchison†

* The Lunatic Asylum of the Charles Arms Laboratory, Division of Geological and Planetary Sciences, California Institute of Technology, Pasadena, California 91125, USA
† Mineralogy Department, British Museum (Natural History), Cromwell Road, London SW7 5BD, UK

The radioactive decay of ^{26}Al, to form ^{26}Mg, may have constituted an important heat source for melting of small planetary bodies in the early Solar System. Although large excesses of radiogenic ^{26}Mg, arising from *in situ* decay of ^{26}Al (half life $\sim 7.2\times10^5$ yr), have been found in ten carbonaceous and ordinary chondritic meteorites[1,2], the distribution of ^{26}Al in the solar nebula and its importance as a heat source remain to be determined. All previous observations of excess ^{26}Mg are confined to Al-rich minerals in refractory, Ca,Al-rich inclusions (CAIs). An assessment of the distribution of ^{26}Al in the Solar System from these data is difficult because CAIs are only a minor constituent of chondritic meteorites associated with high-temperature nebular processes, and because the initial ^{26}Al/^{27}Al ratio inferred from the CAI data is not constant[3] but varies from the commonly measured value of $\sim 5\times10^{-5}$ to values $<1\times10^{-7}$. Here we report the first observation of radiogenic ^{26}Mg in non-refractory meteoritic material, a plagioclase-bearing, olivine-pyroxene clast chondrule in the Semarkona ordinary chondrite. The inferred initial abundance of ^{26}Al (^{26}Al/^{27}Al $=(7.7\pm2.1)\times10^{-6}$) is sufficient to produce incipient melting in well insulated bodies of chondritic composition. We conclude that planetary accretion and differentiation must have begun on a timescale comparable to the half life of ^{26}Al and that, even if widespread melting did not occur, ^{26}Al heating played a significant role in thermal metamorphism on small planets.

If ^{26}Al was widespread in the nebula and was the heat source for melting small planets, some evidence of this should be preserved in 'old' igneous rocks that cooled on a timescale comparable to the mean life of ^{26}Al. No excesses of ^{26}Mg were found in earlier studies of plagioclase for equilibrated chondrites, achondrites and iron meteorites[4], and from three unequilibrated ordinary chondrites[2]. The preservation of isotope effects is strongly affected by the extent of thermal metamorphism, for which reason the present search for radiogenic ^{26}Mg has focused on the Semarkona chondrite, which is among the least metamorphosed chondrites[5]. Semarkona is a highly unequilibrated, LL-group ordinary chondrite which comprises chondrules and clasts set in a fine-grained matrix containing smectite, calcite and magnetite[6]. *In situ* hydrothermal alteration has selectively affected some chondrules and clasts, suggesting that Semarkona formed in an environment similar to that of the CM2 carbonaceous chondrites and is probably petrological type 2.

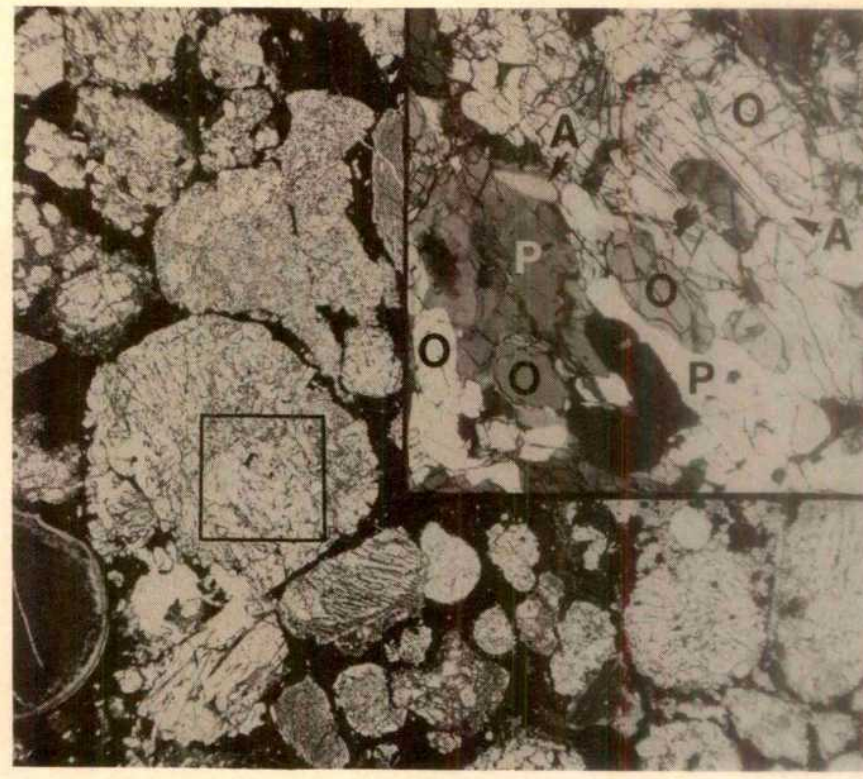

Fig. 1 Optical micrograph (plane-polarized light) of a polished thin section of the Semarkona chondrite. The clast chondrule, CC-1, is indicated by the square; note the roughly pentagonal outline. The square is 500 μm across. Inset shows an enlarged view of CC-1 contained within the square, as seen with crossed polars. Olivine dendrites (O) are poikilitically enclosed in pyroxene (P); anorthite (A) occurs as an interstitial phase.

Anorthite was found in a ~1-mm diameter clast chondrule with a roughly pentagonal outline (Fig. 1). The chondrule, 1805-5 CC-1, is composed of olivine dendrites, some of which traverse the whole chondrule, intergrown with pigeonite. Pigeonite crystals range up to 200 μm in length and poikilitically enclose ovoid portions of olivine dendrites. Crystals of both minerals are truncated at the chondrule margin. The pigeonite may be zoned through subcalcic augite to augite. Anorthite is present as an interstitial phase, typically as 40 × 100 μm laths. CC-1 is free from hydrothermal alteration and contains no glass; ilmenite and kamacite occur as trace constituents. Olivine has a minimum compositional range of Fo_{76} to $Fo_{72.5}$ (here Fo denotes forsterite); CaO and Cr_2O_3 contents are 0.28–0.32 and 0.28–0.55 wt%, respectively. Pyroxene has a minimum range of Wo_8En_{64} to $Wo_{37}En_{48}$, with the corresponding range of 0.49 to 1.43 wt% Cr_2O_3 (here Wo and En denote wollastonite and enstatite respectively). Anorthite contains no detectable Na_2O or K_2O (less than 0.08 and 0.03 wt%, respectively) but contains 0.6–0.8 wt% FeO and 0.5–0.65 wt% MgO. Representative chemical analyses are given in Table 1.

The Mg isotope data were collected with the PANURGE IMS-3F ion probe in an automated peak-jumping mode at a mass-resolving power of 3,300, following techniques discussed by Hutcheon *et al.*[7]. Mass-dependent isotope fractionation (F_{Mg}) is calculated from the deviations in the $^{25}Mg/^{24}Mg$ ratios measured in olivine and pyroxene in CC-1 relative to ratios measured in terrestrial standards. Variations in the $^{26}Mg/^{24}Mg$ ratio are expressed as $\delta^{26}Mg$, relative to $^{26}Mg/^{24}Mg = 0.13955$, and are calculated after normalizing to $^{25}Mg/^{24}Mg = 0.12663$ to correct for instrumental mass fractionation. The $^{27}Al/^{24}Mg$ ratios were calculated from the $^{44}Ca^+/^{24}Mg^+$ ion ratios using a working curve calibrated against electron-probe measurements of terrestrial plagioclase. Abundances of the rare-earth elements (REE) in CC-1 were also measured with PANURGE using an energy-filtering technique[8] at a resolving power of ~500. Concentrations in olivine, pyroxene and anorthite were calculated from REE secondary-ion intensities normalized to the $^{42}Ca^+$ intensity. Pyroxene from the Angra dos Reis achondrite and a synthetic melilite glass[9] were used as standards.

The Mg isotope data (Table 2 and Fig. 2) for CC-1 show small but clearly resolved excesses of ^{26}Mg in five anorthite crystals and isotopically normal Mg in olivine and pigeonite. There is no evidence for isotopically fractionated Mg in any phase, $|F_{Mg}| \leq 3‰$ AMU^{-1}. Excesses of ^{26}Mg (denoted $^{26}Mg^*$) in anorthite range from $\delta^{26}Mg = 2.5 \pm 1.6‰$ to $4.2 \pm 1.8‰$ and are linearly correlated with the $^{27}Al/^{24}Mg$ ratio measured at each point of analysis. The anorthite crystals exhibit only a limited range of Al/Mg ratios; an extensive search for anorthite with Al/Mg > 80 was unsuccessful. These data are characteristic of the *in situ* decay of ^{26}Al in a system with a uniform initial isotope composition, undisturbed by metamorphic processes. In particular, the line defined by the anorthite data is consistent with isotopically normal Mg, as found in olivine and pyroxene, for $^{27}Al/^{24}Mg \ll 1$. The data from the three coexisting phases define an excellent linear correlation on the Al–Mg evolution

Table 1 Chemical analyses of olivine, pyroxene, and plagioclase and the bulk composition of Semarkona CC-1

	1	2	3	4	5	6

1, 2, extremes of olivine composition; 3, 4, extremes of pyroxene composition; 5, typical plagioclase; 6, bulk composition. Data are wavelength-dispersive electron-microprobe analyses except column 6, which is the average of 30 energy-dispersive analyses. Fs is ferrosilite.

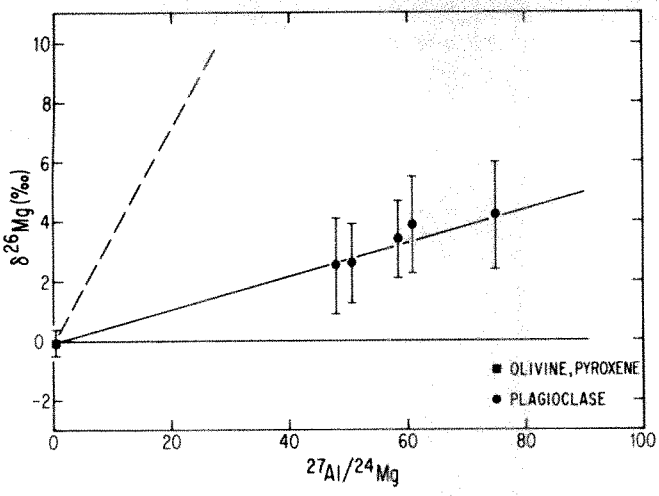

Fig. 2 Al–Mg evolution diagram for coexisting olivine, pyroxene and anorthite in the Semarkona chondrule CC-1. Anorthite contains small excesses of radiogenic ^{26}Mg* clearly resolved from normal Mg. The linear correlation between δ^{26}Mg and Al/Mg is produced by the *in situ* decay of ^{26}Al; the initial ^{26}Al abundance is given by the slope of the solid line through experimental points, $(^{26}Al/^{27}Al)_0 = (7.7 \pm 2.1) \times 10^{-6}$. The dashed line with slope corresponding to $(^{26}Al/^{27}Al)_0 = 5 \times 10^{-5}$ represents the *in situ* decay of ^{26}Al in typical Allende Type B CAI. The horizontal solid line represents normal Mg.

diagram (Fig. 2) with a slope corresponding to $^{26}Mg^*/^{27}Al = (7.7 \pm 2.1) \times 10^{-6}$.

The isotope data from CC-1 demonstrate for the first time that short-lived ^{26}Al was not confined to Ca,Al-rich refractory materials associated with early nebular condensation. This evidence for the *in situ* decay of ^{26}Al in a mafic chondrule from an ordinary chondrite raises two important issues: (1) Does the abundance of ^{26}Mg* in CC-1 provide chronological information on the formation of chondrules? (2) Is the inferred abundance of ^{26}Al sufficient to cause melting of chondritic planetesimals? The initial $^{26}Al/^{27}Al$ ratio indicated by the CC-1 data is approximately a factor of six less than the value of $\sim 5 \times 10^{-5}$ which is characteristic of many Allende type B1 CAIs. If this difference is due to the decay of ^{26}Al from a uniform initial value, then Semarkona CC-1 formed $\sim 2 \times 10^6$ yr after many type B1 CAIs. However, the large variation in $^{26}Mg^*/^{27}Al$ ratios measured in CAIs[3] strongly suggests that the $^{26}Al/^{27}Al$ ratio was heterogeneous in the solar nebula. Differences in inferred $^{26}Al/^{27}Al$ ratios cannot, therefore, be attributed to differences in age. The presence of 'live' ^{26}Al in CC-1 does require that the parent rock solidified very early, within 10^7 years of the time of the ^{26}Al production and not more than a few million years after refractory inclusions.

The interpretation of this evidence of the *in situ* decay of ^{26}Al in terms of the abundance of ^{26}Al in the solar nebula depends critically on the identification of CC-1 as a non-refractory chondrule or fragment produced by igneous activity on a planetary body. The modal mineralogy (olivine 59%, pyroxene 34%, anorthite 7%) and bulk composition (column 6, Table 1) clearly show that CC-1 does not consist of Ca,Al-rich refractory material. The angular form, with crystals terminating abruptly against (rather than nucleating on) the chondrule margin, the mineral chemistry (Table 1) and the exceptionally low Na/Al ratio indicate that CC-1 is a noritic clast chondrule of the poikilitic variety[10], that is, an abraded fragment of an igneous rock and not a quenched liquid droplet. As a group, noritic chondrules have affinities to lunar ANT rocks and to the eucrites[11,12] and most plausibly formed from volatile-poor, differentiated planetary material.

The abundance and distribution of rare-earth elements in CC-1 strongly support a planetary, rather than nebular, origin. The bulk REE content of CC-1 is dominated by the contribution from pyroxene. The REE pattern in high-Ca pyroxene is strongly fractionated, with the heavy REEs (HREEs) enriched; chondrite-normalized abundances (except Eu) increase smoothly from ~0.4 for La to ~5 for Tm. Anorthite exhibits a complementary, HREE-depleted pattern with chondrite-normalized abundances (except Eu) less than unity and a large, positive Eu anomaly ($Eu/Sm \approx 38$). REE abundances in olivine are very low, ≤ 0.01 times chondritic levels for all REEs except La and Yb. The respective REE patterns are characteristic of the partitioning of REEs between basaltic liquid and crystallizing anorthite and pyroxene. The anorthite REE pattern is qualitatively similar to that of plagioclase from the Serra de Magé eucrite[13], although the magnitude of the Eu anomaly in CC-1 anorthite is ~30% greater, comparable to Eu anomalies found in lunar anorthosites[14,15]. The REE abundances in high-Ca pyroxene are in good agreement with predicted REE concentrations based on augite/liquid distribution coefficients[16,17] for a parent liquid with levels of REEs about 8 times those in chondrites.

The mineralogical and chemical evidence argues convincingly for a planetary, rather than nebular, origin for CC-1. The presence of excess ^{26}Mg* in CC-1 indicates that small planetary bodies accreted early and incorporated a substantial amount of ^{26}Al. If CC-1 therefore represents a fragment of early crystallizing material, melting and the production of differentiated liquids must have occurred on a timescale comparable to the mean life of ^{26}Al. During and after crystallization, cooling must have been rapid, and sub-solidus equilibration minimal; otherwise, olivines would have lost CaO and Cr_2O_3 (incorporated into olivine as the primary liquidus phase before pyroxene nucleation) to their neighbouring pyroxenes.

The magnitude of planetary heating caused by ^{26}Al depends primarily on the abundance of ^{26}Al and on the characteristic thermal diffusivity of the body, $\eta = \pi\kappa t/\rho C_p a^2$, where κ is the thermal conductivity, ρ is the density, C_p is the specific heat, a is the planetary radius and t is the time after accretion. For $\eta \ll 1$, the centre of the planet is effectively insulated and most of the heat is retained. In this limiting case, corresponding to $a \geq 30$ km for a compact, chondritic body, the maximum central temperature is linearly related to the ^{26}Al content[4]. For the ratio $^{26}Al/^{27}Al \approx 8 \times 10^{-6}$ inferred for CC-1, ^{26}Al heating will produce central temperatures of ~1,100 °C in a chondritic body. This ratio refers to the ^{26}Al abundance at the time CC-1 became closed to Mg and Al diffusion, and represents a lower limit to the ^{26}Al abundance at the time at which planetary bodies formed. ^{26}Al will be much more abundant and central temperatures will be much higher in bodies that accreted earlier. Incipient melting will occur ($T \geq 1{,}200$ °C) in chondritic bodies accreting only ~70,000 yr earlier, and melting will be widespread in bodies formed more than 100,000 yr earlier.

Detailed solutions to the heat diffusion equation[18] show that,

Table 2 PANURGE ion-probe analyses of the Mg isotope composition of olivine, pyroxene and plagioclase in Semarkona CC-1

Phase	Δ^{25}Mg (‰)†	δ^{26}Mg (‰)‡	$^{27}Al/^{24}Mg$

even if ^{26}Al did not produce widespread melting, it was probably a dominant factor driving thermal metamorphism on small planets. For $^{26}Al/^{27}Al = 8 \times 10^{-6}$, the central 25-km-diameter region of a 40-km-diameter, solid chondritic body ($\kappa \approx 0.007$ cm^2 s^{-1}) will be heated to temperatures exceeding 500 °C. Temperatures will remain at over ~500 °C in the central region for ~1.5–3.6×10^6 yr, depending on the distance from the centre. In a porous, loosely compacted body, the thermal diffusivity is much lower ($\kappa \leq 0.0002$ cm^2 s^{-1}) and temperatures exceeding 500 °C are obtained in the central 8-km region of a 10-km-diameter body. Similarly, the low thermal diffusivity of a thick (~50–100-m) regolith will reduce conductive heat loss and increase interior temperatures relative to the value given above for a solid body.

Estimates of metamorphic temperatures of ordinary chondrites range from ~250–400 °C for type 3 to ~750–950 °C for type 6. Sufficient heat should be generated by decay of ^{26}Al in the interiors of 10–100-km-diameter bodies that accreted early and incorporated ^{26}Al at the level inferred for Semarkona CC-1 to account for the majority of the metamorphic features in types 3, 4 and 5 ordinary chondrites.

Semarkona CC-1 is the first anorthite-bearing chondrule from an ordinary chondrite that we have examined for radiogenic $^{26}Mg^*$. If ^{26}Al was an important heat source, evidence of $^{26}Mg^*$ should be found in similar plagioclase-bearing chondrules in other unequilibrated ordinary chondrites. Hinton and Bischoff[2] failed to detect $^{26}Mg^*$ in plagioclase in Al-rich chondrules from three ordinary chondrites, but excess $^{26}Mg^*$ at the level present in Semarkona CC-1 would not have been detected in their study. A more extensive survey of the Mg isotope composition of plagioclase-bearing chondrules and fragments in unequilibrated ordinary chondrites is required to establish the average initial abundance of ^{26}Al.

We thank D. A. Papanastassiou and G. J. Wasserburg for helpful comments, A. Kennedy for assistance with REE measurements, J. S. Wen for assistance with the heat-conduction calculations and the US National Museum for the loan of the Semarkona section. Thoughtful reviews were provided by R. Hinton and E. Zinner. Formation of chemically active chlorine compounds by reactions of atmospheric NaCl particles with gaseous N_2O_5 and $ClONO_2$

B. J. Finlayson-Pitts, M. J. Ezell & J. N. Pitts Jr

Department of Chemistry and Biochemistry,
California State University, Fullerton, California 92634, USA

Particulate NaCl and NaBr are known[1,2] to react with NO_2 in air at concentrations of a few parts per 10^6 (p.p.m.) to form the corresponding nitrosyl halides XNO (X = Cl, Br), a process that may contribute to the photochemistry of polluted marine areas and remote regions such as the Arctic[3,4]. Here we report experimental evidence that gaseous chlorine nitrate ($ClONO_2$) and dinitrogen pentoxide (N_2O_5) at p.p.m. concentrations also react with NaCl particles at 298 K, to form Cl_2 and $ClNO_2$ respectively. Thus, the chloride ion in a neutral salt can be transformed into gaseous, photochemically active forms of chlorine at 298 K in a manner analogous to that reported recently for the reactions of HCl in ice with $ClONO_2$ and N_2O_5 at 185–200 K (refs 5–8). This work suggests that reactions of N_2O_5 with NaCl in tropospheric marine areas, and possibly in cold climates where chloride salts are used on roads in the winter, should be considered in assessing the atmospheric chemistry of these regions. Furthermore, if the reactions of $ClONO_2$ and N_2O_5 with NaCl occur also at stratospheric temperatures and if NaCl is present in significant concentrations, these reactions may provide another mechanism for recycling ionic halide ions into gaseous species and hence should be considered in models of stratospheric ozone depletion.

Studies of the composition of particles collected in marine air environments, which are composed primarily of sea salt, frequently have a deficiency of chloride ions, as well as other halides such as Br^-, relative to sodium[9]. This has often been attributed[10,11] to ion-exchange reactions of the atmospheric acids HNO_3 and/or H_2SO_4, forming HCl. More recently, NO_2, at concentrations from a few thousand to a few p.p.m., was shown to react with NaCl and NaBr, forming the corresponding nitrosyl halides and sodium nitrate[1,2,12,13].

Recent investigations[5–8] of heterogeneous reactions relevant to stratospheric ozone depletion, particularly in the Antarctic, have established that the following reactions, which are slow in the gas phase[14–17], occur rapidly when HCl is dissolved in ice:

$$HCl + ClONO_2 \xrightarrow[\text{ice}]{} Cl_2 + HNO_3 \quad (1)$$

$$HCl + N_2O_5 \xrightarrow[\text{ice}]{} ClNO_2 + HNO_3 \quad (2)$$

These reactions serve to recycle the reservoir species $ClONO_2$ and HCl into more active forms of chlorine as a result of the rapid photolysis of the products Cl_2 and $ClNO_2$ in the Antarctic spring.

We show here that, in a manner analogous with reactions (1) and (2), $ClONO_2$ and N_2O_5 react readily with NaCl(s) at 298 K. This suggests that recycling of Cl^- from solids into photochemically active gaseous chlorine compounds is a general phenomenon, rather than being restricted to the HCl/ice system. This may have implications for the chemistry of both the troposphere and the stratosphere.

The reaction of NaCl with $ClONO_2$, prepared using the method of Molina *et al.*[18], was studied using both mass spectrometry (MS) and ultraviolet spectrometry (UVS). The MS apparatus is described in detail elsewhere[1,2,9]. Mixtures of $ClONO_2$ (1.7–19%) in He (ultra-high purity, >99.995%) flowed through a needle valve into a low-pressure system operated at 0.11–0.7 torr. On the low-pressure side, the $ClONO_2$/He passed either through a glass bypass or through a cylindrical cell packed with NaCl. It then flowed into a mass spectrometer (dual-chamber Extrel EMBA II equipped with an 800-Hz tuning-fork chopper, lock-in amplifier and Teknivent Vector/One computer interface). Concentrations of $ClONO_2$ reacting with NaCl were $(3.8–11.9) \times 10^{14}$ cm^{-3}, corresponding to 15–48 p.p.m. if mixed with air at 1 atm. The residence time of the $ClONO_2$ in the NaCl-packed cell is estimated to be ~5–10 s.

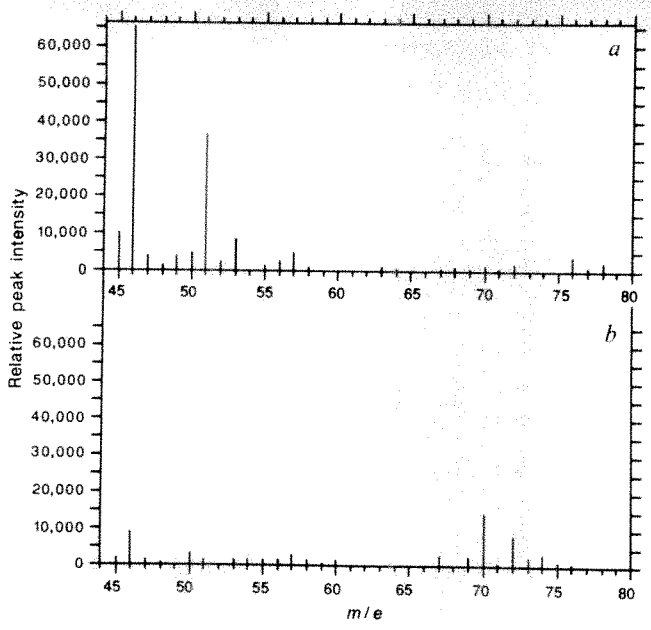

Fig. 1 Mass spectra of $ClONO_2$ when passed through the bypass (*a*), or passed over NaCl at 298 K (*b*). When $ClONO_2$ is exposed to NaCl, the peaks from $ClONO_2$ at $m/e = 46$, 51 and 53 drop significantly and those from Cl_2 at $m/e = 70$, 72 and 74 appear. Initial concentration of $ClONO_2$ was 7.5×10^{14} cm^{-3}; total pressure of He was 0.112 torr. Intensities greater than 65,535 are off scale.

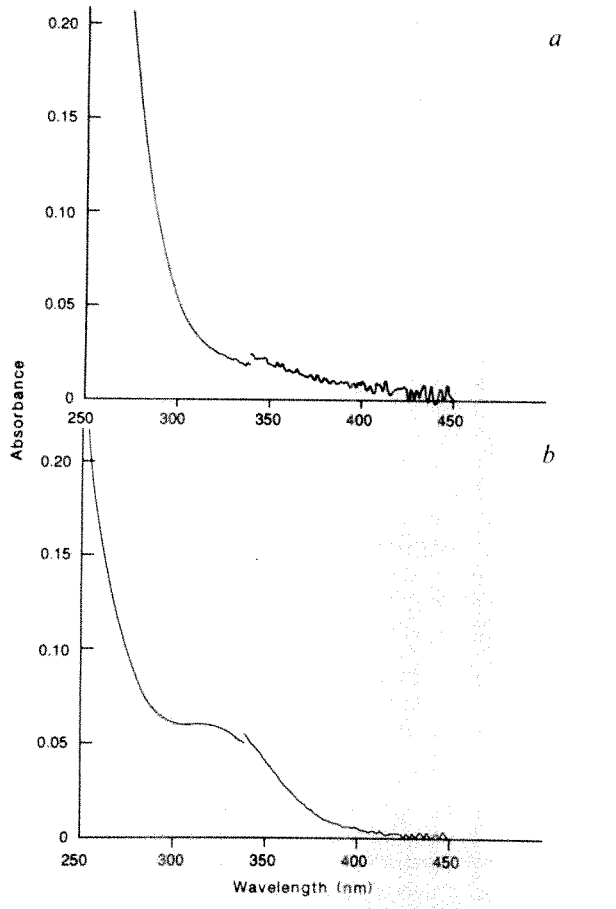

Fig. 2 Ultraviolet spectra of $ClONO_2$: *a*, at 9.2 torr, unreacted, and *b*, at 3.8 torr $ClONO_2$ after reacting with NaCl at 298 K for 71 min. The increased absorbance at ~320 nm is due to the Cl_2 formed in the $ClONO_2$–NaCl reaction.

In these and the N_2O_5 experiments reported below, the NaCl, which was present in excess compared with the gaseous reactants, was heated for several hours under vacuum before exposure to the gases; however, trace amounts of water may be present.

Figure 1 shows the mass spectra in the region $m/e = 44$–80, obtained either when $ClONO_2$ bypasses the NaCl (Fig. 1*a*) or when it flows over the NaCl (Fig. 1*b*). The mass spectrum of the unreacted $ClONO_2$ in Fig. 1*a* shows peaks at $m/e = 46$, 51 and 53 resulting from fragmentation of the parent molecule; it is likely that NO_2 impurity also contributes to the $m/e = 46$ peak. No peaks are seen at $m/e = 70$, 72 or 74, which are characteristic of Cl_2; in independent runs, the Cl_2 impurity in the $ClONO_2$ was estimated to be <0.2%. When $ClONO_2$ passed over the NaCl, however, the peaks characteristic of $ClONO_2$ fell dramatically and those characteristic of Cl_2 appeared (Fig. 1*b*).

Further confirmation of the formation of Cl_2 was obtained using UVS. For these measurements 3.8 torr of $ClONO_2$ in 1 atm air (ultra-high purity, <0.01 p.p.m. total hydrocarbon content, <0.01 p.p.m. CO, <0.001 p.p.m. NO_x, <0.001 p.p.m. SO_2) was allowed to react with ~100 g NaCl in a 5-litre bulb for 71 min. The gas over the salt was then expanded into a 10-cm quartz cell and repressurized with air to 1 atm. Figure 2 compares the UVS spectrum (Fig. 2*b*) of the $ClONO_2$ after reaction with NaCl with that of a higher concentration of unreacted $ClONO_2$ (Fig. 2*a*). The increased absorbance at 320 nm after reaction is characteristic of Cl_2. Using published absorption cross-sections[19], it is estimated that ~40% of the $ClONO_2$ was converted to Cl_2.

Thus both the MS and UVS studies imply the occurrence of the reaction

$$NaCl(s) + ClONO_2(g) \rightarrow Cl_2(g) + NaNO_3(s) \qquad (3)$$

with enthalpy change $\Delta H_0^{298} = -82.8$ kJ mol^{-1}.

In a second set of experiments, N_2O_5 was prepared by reacting NO_2 with excess O_3 and condensing the N_2O_5 at 195 K. Dilute mixtures of N_2O_5 in 1 atm air were expanded simultaneously into the reaction cell and into a 7-litre Fourier-transform infrared (FTIR) multi-pass cell with White cell optics (0.8 m base path, 40 m total pathlength), and both were repressurized to 1 atm with air. The spectrum of the initial N_2O_5/air mixture was recorded using a Mattson Sirius 100 FTIR spectrometer at 2-cm^{-1} resolution with 64 scans. The reaction cell was a 5-litre bulb to which was attached a 200-ml bulb containing ~100 g of NaCl; concentrations of N_2O_5 during the exposure were 2.9–216 p.p.m. The reaction bulb was rotated to thoroughly mix the salt with the gas and then allowed to react in the dark for ~1 hour. The reacted gas mixture was expanded into the FTIR cell, repressurized to 1 atm with air and the spectrum recorded.

Figure 3*a* gives a typical spectrum of the initial reactant mixture in the region 1,300–700 cm^{-1}, showing the bands from N_2O_5 as well as those from some HNO_3 impurity. Figure 3*b* shows the spectrum of the gases after reaction with NaCl for 64 min. The reactant N_2O_5 has disappeared and bands from nitryl chloride[20] ($ClNO_2$) are present, implying the reaction

$$NaCl(s) + N_2O_5(g) \rightarrow ClNO_2(g) + NaNO_3(s) \qquad (4)$$

for which $\Delta H_0^{298} = -55.2$ kJ mol^{-1}. The yield of $ClNO_2$ was approximately proportional to the initial N_2O_5 concentration, as expected if N_2O_5 is the limiting reagent. When small amounts of impurity HNO_3 were present in the reactant, infrared bands from HCl centred around 2,885 cm^{-1} were also observed, as expected for the HNO_3–NaCl reaction[10,11]. Hence, when acid is present, it reacts with NaCl in competition with N_2O_5.

According to reactions (3) and (4), the second product of both reactions should be $NaNO_3$. To confirm this, thin pressed plates were made from the NaCl which had been exposed to either N_2O_5 or $ClONO_2$ and the infrared transmission spectra recorded. Figure 4 shows the spectra of NaCl in the 1,500–800 cm^{-1} region after exposure to N_2O_5 (Fig. 4*a*), after exposure

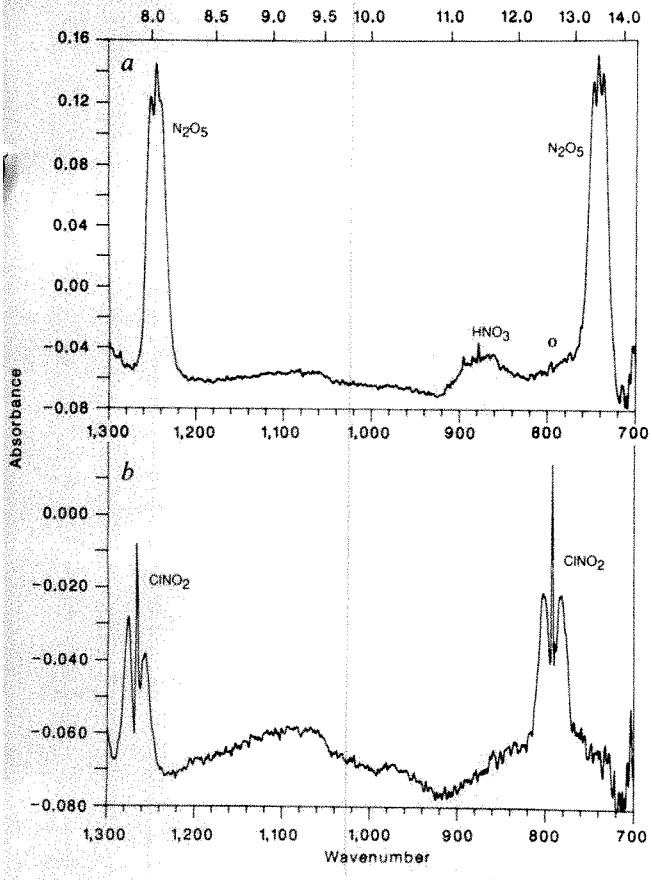

Fig. 3 Infrared spectra of 6.1 p.p.m. N_2O_5 in 1 atm air at 298 K, *a*, before and *b*, after reaction with NaCl for 64 min, showing that $ClNO_2$ is formed.

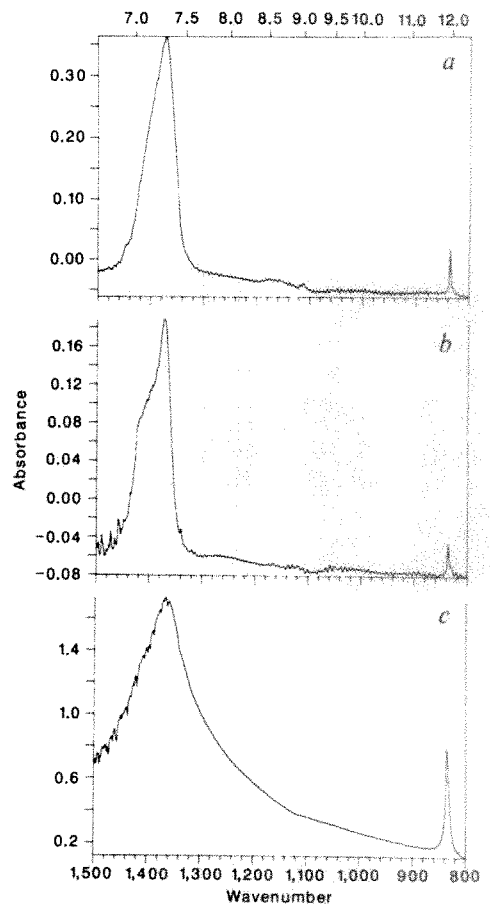

Fig. 4 Infrared spectra of $NaNO_3$ formed in the reactions of NaCl with 1.9 torr N_2O_5 (*a*) and NaCl with $ClONO_2$ (*b*) during mass spectrometry studies (see text). For comparison, *c* shows the spectrum of an authentic sample of a 12.6% $NaNO_3$/NaCl mixture. All spectra referenced to unexposed NaCl.

to $ClONO_2$ (Fig. 4*b*) and for comparison, the spectrum of a $NaNO_3$/NaCl mixture (Fig. 4*c*). Clearly $NaNO_3$ is also a reaction product.

Thus, at room temperature both N_2O_5 and $ClONO_2$ react with solid NaCl in a manner analogous to reactions (1) and (2). In conjunction with our earlier work[1,2], which showed that NO_2 reacts with NaCl and NaBr to form ClNO and BrNO respectively, these studies indicate that recycling of halide ions in salts into gaseous, photochemically active forms can occur through a variety of reactions with species commonly encountered in the atmosphere. The fact that reactions (3) and (4) occur readily suggests that acid catalysis need not be invoked as a necessary condition for the conversion of inactive forms of chlorine into photochemically active gaseous species in either the troposphere or the stratosphere[10,11,21,22].

In the troposphere, the major source of NaCl in particles is as seasalt particles formed by wave action. Thus in polluted marine areas, where NO_2, HNO_3 and N_2O_5 are present, production of ClNO, HCl and $ClNO_2$ may occur, in relative amounts that depend on the concentrations of the gas-phase species and the speeds of the individual reactions. Typical peak concentrations of NO_2, HNO_3 and N_2O_5 in Los Angeles, for example, are ~100 parts per 10^9 (p.p.b.), 50 p.p.b. (ref. 9) and 15 p.p.b. (ref. 23; recent calculations (H. Biermann *et al.*, personal communication) suggest that this N_2O_5 value may be ~8 p.p.b.) respectively. The reaction efficiencies are not known, but we are currently measuring them. However, if the reaction of NaCl with N_2O_5 is approximately an order of magnitude faster than that with NO_2, in heavily polluted marine environments it would compete with the NO_2–NaCl reaction.

Both N_2O_5 and $ClONO_2$ hydrolyse on surfaces on which water is adsorbed[9,24]; hydrolysis of N_2O_5 will thus compete with its reaction with NaCl in the troposphere. Field measurements of NO_3 (which forms N_2O_5 and is in thermal equilibrium with it) indicate, however, that at relative humidities (RH) $\leq$50%, the lifetimes of NO_3 and hence N_2O_5 can be significant in the troposphere[23,25]. The deliquescence point of NaCl is ~75%, so that salt particles formed by wave action will be relatively dry at RH $\leq$ 50% and hence under these conditions the N_2O_5–NaCl reaction may be important.

All studies reported here were carried out at room temperature, but it seems reasonable that these reactions will continue to occur at a significant rate at lower temperatures. Chlorine nitrate is a polar molecule with the chlorine being the positive end; large dipole–dipole interactions with ionic NaCl should lead to the rapid formation of an ion-pair adduct which could rearrange as follows:

$$ClONO_2 + NaCl \rightarrow \begin{matrix} Cl^- & \cdots\cdots & Na^+ \\ \vdots & & \vdots \\ Cl^+ & \cdots\cdots & ONO_2^- \end{matrix} \rightarrow Cl_2 + NaNO_3$$

If there is no activation energy for the reaction, lower temperatures may increase the reaction efficiency by increasing the residence time of the $ClONO_2$ on the surface, as suggested by Molina *et al.*[5] for the $ClONO_2$–HCl/ice reaction.

If both reactions (3) and (4) do occur at significant rates at lower temperatures, they may play a role in the chemistry both of colder regions of the troposphere and of the stratosphere. For example, N_2O_5 could react with chloride salts used on roads

in winter, or indeed with frozen seasalt particles, to form $ClNO_2$, which could then photolyse or undergo other secondary reactions. In addition, by analogy with the studies on NO_2–NaCl and NaBr, other halide salts such as NaBr, if present, would be expected to undergo similar reactions; we are currently studying these systems. Such possibilities should be considered in models of tropospheric chemistry.

Whether NaCl is present in the stratosphere in significant quantities from such sources as meteor ablation or tropospheric injection is subject to some controversy[26–30]. If it is found, our work suggests that reactions (3) and (4) with $ClONO_2$ and N_2O_5 represent other possible mechanisms for recycling Cl^- into active forms. One key factor which may limit the importance of these reactions in recycling any stratospheric NaCl is that once the surface layer has been oxidized to $NaNO_3$, this may effectively prevent further reaction. In contrast, in reactions (1) and (2) the HCl throughout the ice diffuses rapidly to the surface; thus all of the dissolved HCl, not only that on the surface, is available for reaction[5–8].

There are several major caveats in extrapolating our studies to atmospheric, particularly stratospheric, conditions: they were carried out only at room temperature, in the absence of water or other co-pollutants and at higher concentrations than are found in the atmosphere. However, the mechanistic implications for the analogous reactions (1) and (2), which play key roles in stratospheric ozone loss particularly in the Antarctic, are sufficient to argue that the possible roles of reactions (3) and (4) in atmospheric chemistry should be investigated further. We are currently exploring the effects of temperature and water on reactions (3) and (4), and measuring the reaction efficiencies.

We are grateful to the NSF for support of this work, and to Mr Stanley Johnson and Mr Frank Livingston for experimental assistance. We also thank Dr L. T. Molina for helpful discussions on the preparation of $ClONO_2$.

Image processing using light-sensitive chemical waves

L. Kuhnert*, K. I. Agladze† & V. I. Krinsky†

Image processing is usually concerned with the computer manipulation and analysis of pictures[1]. Typical procedures in computer image-processing are concerned with improvement of degraded (low-contrast or noisy) pictures, restoration and reconstruction, segmenting of pictures into parts and pattern recognition of properties of the pre-processed pictures. To solve these problems, digitized pictures are processed by local operations in a sequential manner. Here we describe a special light-sensitive chemical system, a variant of the Belousov–Zhabotinskii medium, in which chemical reaction fronts ('chemical waves') can be modified by light. Projection of a half-tone image on such a medium initiates a very complex response. We are able to demonstrate contrast modification (contrast enhancement or contrast decrease up to contrast reversal from positive to negative and vice versa), discerning of contours (for example, segmenting of pictures up to the extreme case of skeletonizing) and smoothing of partially degraded pictures.

This light-sensitive chemical medium clearly works as a special image processor, and in contrast to sequential computer processes it can be considered to operate as a parallel process. The chemical medium used is a light-sensitive variant of the well-known Belousov–Zhabotinskii (BZ) reaction[2–4]. This reaction is the best studied example of self-organization in nonlinear chemical systems operating far from equilibrium. In homogeneous well stirred solutions, temporal oscillations, bistability and deterministic chaos are observed. In distributed systems, however, if the reaction proceeds in a thin layer of reagent, spontaneous breaking of spatial symmetry occurs. Spatially propagating chemical-reaction fronts (so-called chemical waves) are observed, and two types of waves have been distinguished. If the reagent is in an oscillatory regime and the period of oscillations depends on the spatial coordinate, then a 'phase wave' spreads over the layer. Its velocity is inversely proportional to the phase gradient, as is the case in other physical phase-wave phenomena. The other type of wave, the 'trigger wave', is generated through autocatalytic feedback related to diffusion in the excitable regime. Trigger waves propagate with constant velocity according to a reaction-diffusion mechanism. Chemical trigger waves can be considered as analogous to propagation of flame fronts or of a grass fire. Trigger waves may also occur in the oscillatory regime if a very high phase gradient has been established, as in the case of a chemical system with a high concentration gradient of chemical substances. In such a case the velocity of phase waves is very low and trigger waves can dominate.

Table 1 Compositions of the light-sensitive BZ reagent

	Composition 1 (mol l^{-1})	Composition 2 (mol l^{-1})
$NaBrO_3$	0.3	0.3
H_2SO_4	0.6	0.4
Malonic acid	0.2	0.2
Bromomalonic acid	0.1	0.1
$Ru(bipy)_3Cl_2$	0.0025	0.0025

The BZ reaction occurs between bromate ions and an organic substrate (preferably malonic acid) in acidic conditions, in the presence of a metal-ion redox catalyst[5]. In the light-sensitive variant, the ruthenium bipyridyl complex $Ru(bipy)_3^{2+}$ is used as the catalyst. The main steps in the complicated reaction network of the BZ reaction are autocatalytic oxidation of the catalyst and reduction of the oxidized catalyst by the brominated organic

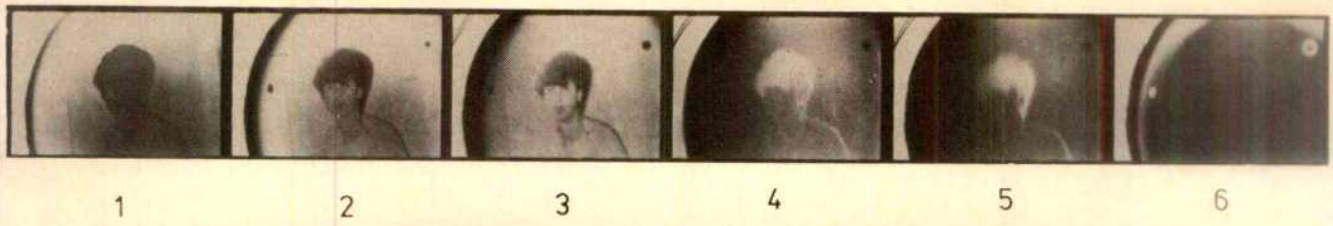

Fig. 1 Light-sensitive BZ reaction (composition 1; Table 1) with a negative image projected onto it. Frame 1: appearance of an image; 2, 3: positive image; 4, 5: negative image; 6: transient phase. The cycle shown here then recurs.

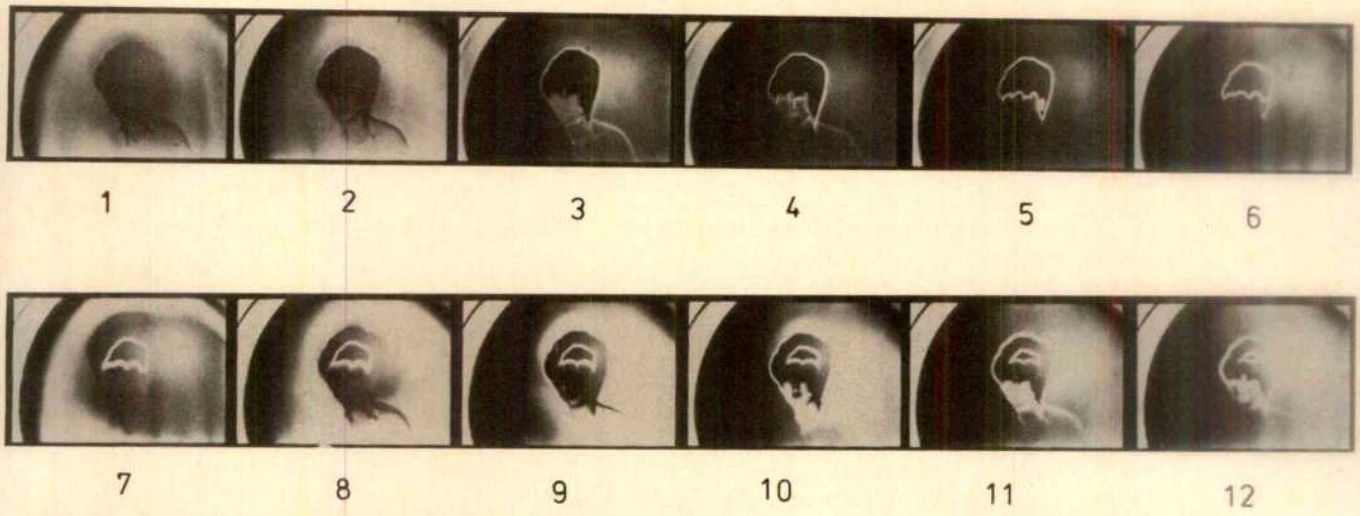

Fig. 2 Image-contour discernment. Same projection as in Fig. 1, but using reagent composition 2 (Table 1). Frames 1, 2: positive image; 3, 4: the dark portion of the image acquires contours; 5–8: erosion of the contour images by trigger waves, which is the mechanism of skeletonizing; 9, 10: formation of a new contour outside the former retracting one; 11, 12: the two retracting contours now fit into one another.

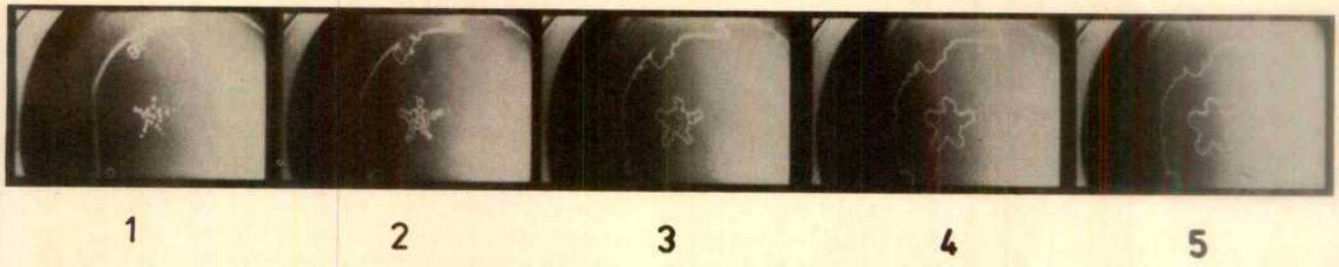

Fig. 3 Smoothing of a discontinuous image. The image, consisting of separate black points against a bright background, was projected on a Petri dish containing the light-sensitive BZ component of composition 2. Frame 1: an image appears as light points against the dark background; 2: each point becomes a source of a propagating concentric wave; 3: waves merge, producing a smoothed image; 4, 5: the image grows in size, and the degree of smoothing increases.

substrate. In the reduction step, liberated bromide ions act as inhibitors to autocatalytic oxidation; thus, bromide is the most important control intermediate and its concentration controls the reaction regime[5,6]. The light-sensitive Ru-catalysed system offers the possibility of selecting the rate of bromide production by photochemical means. By illuminating a distributed system we can control the propagating effects, and, for particular light intensities, observe bifurcations between several reaction regimes. As a consequence, starting in an oscillatory regime and illuminating with increasing light intensity, we can control the velocity of phase waves, transform phase waves into trigger waves, control the velocity of trigger waves and, at very high light intensity, inhibit propagating phenomena completely. By projecting a half-tone image onto a thin layer of reagent, the light intensity is varied as a function of optical density and spatial coordinate. The chemical-wave phenomena are influenced accordingly, and several reaction regimes (for example, phase waves and trigger waves) may be observed in the same layer.

Figures 1–3 show some examples of time sequences of image processing performed by such a system. Fig. 1 demonstrates the possibility of controlling the contrast of an image, Fig. 2 illustrates contour delineation and Fig. 3 shows smoothing of discontinuous images. In these experiments a negative image was projected onto a thin layer (0.8 mm) of the reagent contained in a Petri dish of 9 cm diameter maintained by thermostat at 12 °C. Two reagent compositions were used, distinguished only by acidity (Table 1); composition 1 was used for contrast control and composition 2 for contour discernment and image smoothing. The time interval between the frames in Figs 1–3 was 10 s. In the initially homogeneous solution, there appeared first an inhomogeneity resulting from the influence of the projected image (frame 1 in Figs 1 and 2) and then the positive image itself (frame 2, Figs 1 and 2). For composition 1 (the more acidic solution, in which the oscillatory regime is more pronounced), projection of the negative causes only a change in the oscillatory period, whereas for composition 2 (lower acidity) the same projection causes a transformation from the oscillatory regime

(phase waves) to the excitable regime (trigger waves) in the brightest parts of the image, with the result that contours may be discerned.

In Fig. 1, the change in contrast of the image is accompanied by periodic positive-to-negative transitions, and in Fig. 2 the image contour is revealed. In the latter case, the contour of the brightest part of the image appears first (frame 3), and is then seen to shrink towards the centre of the image (frames 4–8). The process recurs periodically, creating a set of contours inscribed in one another and shrinking successively.

Projecting an image containing discontinuities initiates waves that merge during propagation to cause smoothing of the image (Fig. 3). During the exposure time (t), discontinuities with a length less than $l = \frac{1}{2} vt$ (where v is the propagation velocity of concentration waves in the chemical reaction) will become smoothed.

Let us consider the simplest mechanism of image processing by this light-sensitive reaction. Like the BZ reaction itself, this reaction has an oscillatory character; each point of the system alternates between a fluorescent blueish and an orange colour with a period of ~1–2 min. If a particular arrangement of blue and orange regions is prearranged in the reaction layer (by drawing on the reagent surface with a silver wire), then positive-negative image transitions will be observed (the orange colour being replaced by blue and vice versa) with a period equal to the reaction auto-oscillation period. Such an orange-blue configuration can alternatively be prearranged by projecting onto the medium a half-tone negative (Fig. 4*a*, top). Initially, no image appears in the reaction layer when projection commences, despite the spatial differences in illumination intensity (phase t_1 in Fig. 4). As time progresses, then because the reaction is light-inhibited (and therefore the auto-oscillation period is greater in the illuminated areas than in the non-illuminated areas), the change in colour occurs first in the non-illuminated areas (phase t_2); the initial negative image changes to a positive one. Then, because of auto-oscillations, the reverse takes place (phase t_3), whereupon the process repeats periodically.

Such transitions can be seen in Fig. 1 for a real image with a continuous distribution of illumination intensity. Frame 1 corresponds to the termination of phase t_1, frames 2 and 3 to phase t_2, frames 4 and 5 to phase t_3, and frame 6 again to phase t_1. In this case the contrast changes smoothly from a maximum through zero to the negative region (negative image).

By increasing the range of illumination intensity (or by changing the reagent composition), it is possible to discern the image contours (Fig. 2). In the simplest case, a contour is discerned which is a boundary between auto-oscillating and excitable regions, as illustrated in Fig. 4*b*. The concentration of bromide, c, which inhibits autocatalytic oxidation, determines the reaction mode: for $[Br^-] > c_2$ (Fig. 4*b*), the propagation effects are completely inhibited; for $c_1 < [Br^-] < c_2$, the medium is excitable, and for $[Br^-] < c_1$, the colour oscillates with a period equal to the reaction period (oscillatory regime). In the intermediate regime ($c_1 < [Br^-] < c_2$), propagating waves appear at the boundary of the auto-oscillating and excitable regions (Fig. 4*b*, bottom). A more detailed theoretical description of bifurcations in this reaction system, within the framework of a modified version of the well-known Oregonator model, will be given elsewhere[7].

Note that chemical waves propagating to the centre of an image (Fig. 2, frames 9–12) can be used to discern the image skeleton. Such waves can also be used for image smoothing. Fig. 3 illustrates different stages in the development of a wave pattern resulting from the projection of a fragmentary image. In this case the non-illuminated points serve as leading centres for the creation of new waves, which merge during propagation and result in smoothing of the image. In illuminated areas, trigger-wave propagation is possible but not nucleation of new leading centres; light inhibits the nucleation of new waves.

These results are remarkable for several reasons. First, this system models some operations used in computer image-

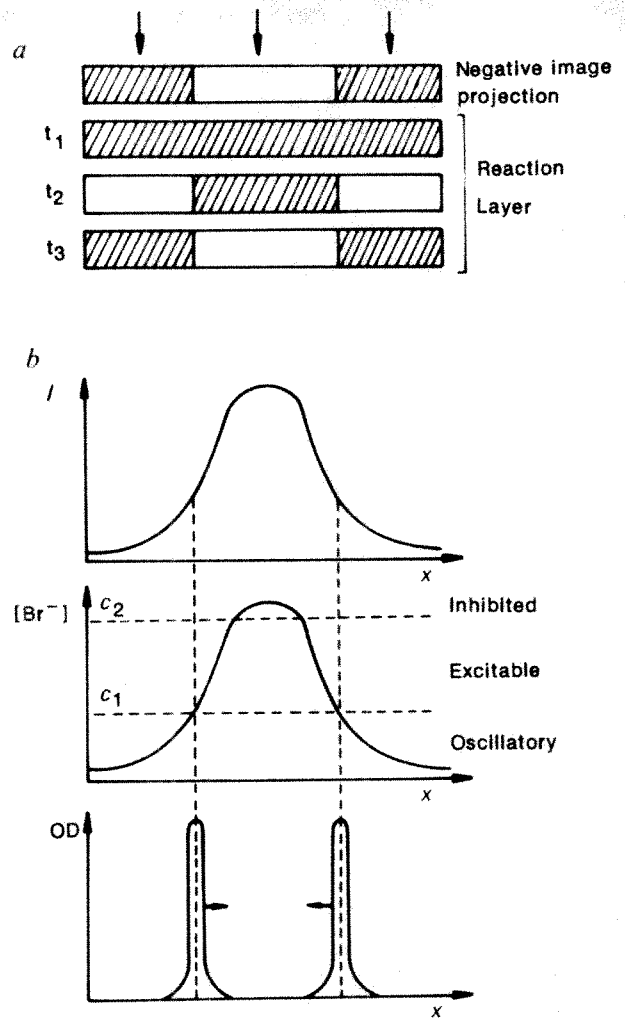

Fig. 4 Mechanism of image processing. *a*, Positive-negative transitions and contrast control. At the top is the negative image projection, and below, three different phases of the reaction (see text). *b*, Contour discernment. Top, illumination intensity of the projected image (I) and corresponding bromide concentration, as functions of the spatial coordinate. Bottom, optical density (OD) in the reaction layer, for the situation in Fig. 2, frame 4 (contouring), which is followed by skeletonizing (frames 5–8).

processing, and might suggest new algorithms (for example, chemical waves can be modelled by cellular automata). Second, there are some speculative connections to visual perception. Contrast enhancement in visual systems is based on the mechanism of lateral inhibition (Mach bands)[8], for example, by neuronal interaction of neighbouring sensor cells. This kind of interaction can also be modelled by molecular diffusion within the framework of a particular chemical model with an autocatalytic step. Third, light-sensitive chemical waves can be seen as a chemical-hardware realization of certain ideas related to new computational systems such as synergetic computers or other network models[9,10] (although in the system described here the interactions are only local). For example, the image smoothing process (Fig. 3) is a realization of an associative memory device: from only an incomplete set of data, the whole pattern may be reconstructed[9]. To construct more sophisticated realizations we require more complex interactions, and in particular long-range interactions. These could be achieved by using special output devices that measure chemical concentration fluctuations at several selected points in the layer. In this way a learning network might be realized by chemical means.

Depletion of soil aluminium by acid deposition and implications for acid neutralization

J. Mulder, N. van Breemen & H. C. Eijck

Department of Soil Science and Geology, Agricultural University, Box 37, 6700 AA Wageningen, The Netherlands

In acid soils acid rain is often largely neutralized by dissolution of aluminium[1-3], which is potentially phyto-toxic[4]. Here we show that only a minor fraction of soil aluminium is readily dissolved. This most soluble fraction consists largely of non-silicate, organically bound aluminium, which has been formed in the course of soil development. The current rapid and irreversible depletion of this fraction constitutes a drastic change in soil genesis. Depletion may eventually result in reduced acid neutralization, as a consequence of decreased dissolution of aluminium, and should be accounted for in soil acidification models.

Dissolution of aluminium in acid soils is one of the most pronounced soil chemical effects of acidic deposition[1-3]. Aqueous aluminium is toxic to crop roots[4-6] and has also been associated with forest die-back[7]. Because of its toxicity the soil chemical behaviour of aluminium has been a major topic in agronomic[8,9] and ecological[10] studies. Most of these studies deal with short-term phenomena such as speciation, exchange characteristics and solubility control. Long-term effects on aqueous aluminium in soils, resulting, for example, from changes in the soil solid phase, are generally ignored. In many acid, sandy soils, however, an appreciable portion of the pools of various solid-phase aluminium fractions is currently leached from the soil. Table 1 indicates that leaching could lead to a significant depletion of certain soil aluminium fractions within several decades. The current depletion rates of extractable aluminium are significantly higher than the rates of aluminium transfer from silicate-bound to extractable soil aluminium. Maximum annual rates of formation of extractable aluminium amount to 0.030 mmol per kg of soil, as estimated from accumulation rates in the soil solid phase[11] (J.M. *et al.*, preprint) and from current rates of organic-aluminium precipitation[11]. Decreasing content of various fractions of solid-phase aluminium could affect the aqueous aluminium concentrations. Insight into these aspects is essential for evaluating long-term effects of acid deposition.

Data on the sources of dissolved aluminium were obtained from a laboratory leaching experiment. Air-dried, <2 mm fractions of soil samples from the Netherlands and New Hampshire, USA, were taken from the surface and sub-surface horizons of two podzols (Haplorthods) and of a recent driftsand (Udipsamment) (Table 1). Duplicate samples of each soil horizon (5.0 g) were leached 10, 25 and 50 times, respectively, with 100 ml aqueous hydrochloric acid at *p*H 3.0. After each acid addition the suspensions were kept in tightly capped centrifuge tubes at 20 ± 2 °C for 24 hours. Suspensions were shaken manually three times in each 24 hours. The suspensions were centrifuged at 2,000 r.p.m. for 15 min, and 80 ml of the clear supernatants was decanted and replaced by 80 ml of fresh HCl solution. Sub-samples of each supernatant were pooled to give a single extract after 10, 25 and 50 HCl treatments. In each case, pooled leachates were analysed for all major solutes, dissolved aluminium concentrations were measured after 6, 24 and 72 hours in one additional leaching, and soil samples were freeze-dried and residual solid aluminium fractions were estimated by sequential selective dissolution (Table 1). Dissolved aluminium was assayed colorimetrically using pyrocatechol-violet.

We selected a leaching solution of *p*H 3.0, because this is close to the current *p*H of the water infiltrating many surface soils of forests and heathlands in north-western Europe[3] (J.M. *et al.*, submitted). We enhanced aluminium mobilization rates relative to those in the field by applying HCl at a rate of 20 mmol H^+ per kg of soil per 24 hours. This is considerably higher than the current acid load in the field (4 mmol H^+ kg^{-1} yr^{-1}).

Table 1 Pools of solid-phase aluminium in three acid, sandy soils from the Netherlands, and one from New Hampshire (USA), before laboratory leaching treatments, and annual aluminium mobilization rates from the respective soil layers in the field

Site	Soil	Depth horizon (cm)	Extractable aluminium* KCl	$Na_4P_2O_7$	$(NH_4)_2C_2O_4$ (mmol kg^{-1})	Total aluminium†	Annual removal of aluminium‡

		15-30 B	5.8	322	51.1	2185	−0.004

* Solid-phase aluminium was extracted using selective dissolution. Soil samples (1 g) were sequentially extracted with 50 ml 1M KCl (0.5 hour), 50 ml 0.1M $Na_4P_2O_7$ (16 hours) and 50 ml 0.2M $(NH_4)_2C_2O_4$ adjusted to *p*H 3.0 (4 hours in the dark)[11]. Extracted amounts represent exchangeable aluminium (KCl), organic aluminium and minor amounts of non-crystalline hydrous oxides ($Na_4P_2O_7$) and most amorphous aluminium hydroxides ($(NH_4)_2C_2O_4$)[16,17]. Extracted aluminium was measured using colorimetry with pyrocatechol violet (KCl), inductive coupled plasma spectroscopy ($Na_4P_2O_7$), and atomic absorption spectroscopy with a nitrous oxide-acetylene flame ($(NH_4)_2C_2O_4$).

† Total aluminium, largely originating from aluminium silicates, was determined by X-ray fluorescence spectroscopy of a lithium tetraborate melt of the soil material.

‡ Calculated from bulk density (kg m^{-3}) (H. F. van Dobben and J. Mulder, manuscript in preparation), and estimated aluminium fluxes (kmol ha^{-1} yr^{-1}) (J.M. *et al.*, preprint). Monthly aluminium fluxes were estimated by multiplying the simulated soil water flux and the measured monthly dissolved-aluminium concentration in the soil solutions collected from suction plates in the field. Values for inorganic aluminium in the Hubbard Brook soils were taken from Driscoll *et al.*[11]. Negative numbers indicate immobilization.

§ Not included in the leaching study.

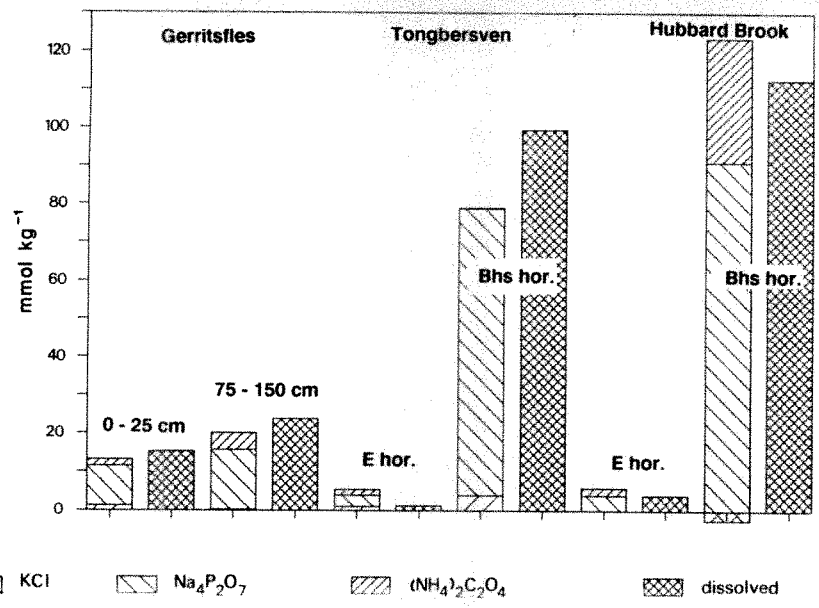

Fig. 1 The decrease in solid-phase aluminium, after 25 leachings with HCl (left bar, hatched) and the amount of aluminium removed in the leachates (right bar, cross-hatched) for six soil samples. Values are means of duplicates. Duplicates of dissolved aluminium were within 37% (E horizons) or 6% (all other horizons) of the mean; duplicates for the depletion of the $Na_4P_2O_7$-extractable fraction were within 38% (E horizons) or 22% (other horizons) of the mean. Note that in the Hubbard Brook Bhs horizon KCl-extractable aluminium increases slightly over the course of 25 leaching cycles. This increase is due to the strong increase in dissolved aluminium relative to that in field conditions[11].

The cumulative amount of aluminium dissolved by HCl is invariably close to the amount of extractable ('free') aluminium removed (Fig. 1). Our data indicate that the dissolution rate of 'free' aluminium is high relative to that of the more abundant aluminosilicates (Table 1). Organically complexed ($Na_4P_2O_4$-extractable) aluminium is the fraction that dissolves most, whereas the exchangeable fraction (KCl-extractable) contributes little to the total dissolved aluminium (Fig. 1). Thus, aluminium is transferred to solution mainly from the organically complexed solid phase, even when the pool of organic aluminium is small.

On addition of HCl, dissolved aluminium concentrations invariably rose to constant values within 24 hours, indicating attainment of chemical equilibrium. Charge balances of the leachates indicate that dissolved aluminium is present mainly as aquo-Al^{3+}. Only in the leachates of the podzol Bhs horizons is a significant fraction (20–30%) of dissolved aluminium organically complexed. (The podzol Bhs is a soil layer rich in organic-aluminium precipitates.) Dissolved aluminium concentrations are significantly correlated with the organic ($Na_4P_2O_7$-extractable) aluminium content of the soil sample (Fig. 2). This further indicates the importance of solid alumino-organics as a major source of dissolved aluminium. Because dissolved aluminium concentrations in our leachates increased rapidly to stable levels, but were highly undersaturated with respect to gibbsite ($pAl-3pH=-8.11$; ref. 13 and Fig. 3), exchange equilibrium between dissolved and adsorbed aluminium as described for forest-floor samples[12] may also hold for solid-phase alumino-organics in our mineral soils.

Following Cronan *et al.*[12], the exchange equilibrium $3H^+ + AlX = H_3X + Al^{3+}$ can be modelled as $[Al^{3+}]/[H^+]^3 = K_{ex}(AlX/H_3X)^n = K_{app}$, where n, K_{ex} (exchangeable) and K_{app} (apparent) are constants, square brackets denote activities of aqueous ions and AlX and H_3X are their mole fractions on the organic sorbent. Taking negative logarithms, this expression becomes

$$pAl - 3pH = pK_{ex} - n\log(AlX/H_3X) = pK_{app}$$

The data in Fig. 3 indicate that pK_{app} increases with decreasing content of solid-phase alumino-organics. Only the first equilibrium extracts of the podzol Bhs horizons (represented by diamonds in Fig. 3) were close to equilibrium with gibbsite.

In general, the KCl-extractable aluminium fraction is assumed to represent readily mobilizable, exchangeable aluminium[14]. However, our data show that in a strongly acidic environment the $Na_4P_2O_7$-extractable aluminium fraction is a better estimate of readily mobilizable aluminium, exchanged against H^+.

In the field, 1–2% of organic aluminium is removed annually from the surface layers of the Dutch soils (Table 1). Note that the current rate of mobilization of aluminium from the uppermost soil layers is lowest where the content of soil organic aluminium is lowest. Based on the content of soil organic aluminium, the mobilization rates of aluminium are potentially high in the spodic B horizons. However, the availability of readily mobilizable aluminium is associated with a rapid acid consumption and consequently an increase in solution pH, which restricts further aluminium mobilization. Soil solutions in Bhs horizons are generally close to equilibrium with gibbsite. In the Dutch podzols the current depletion of alumino-organics is most pronounced in the upper few centimetres of the Bhs horizon, which was formed by precipitation of organic aluminium in the course of soil development. In such soils the

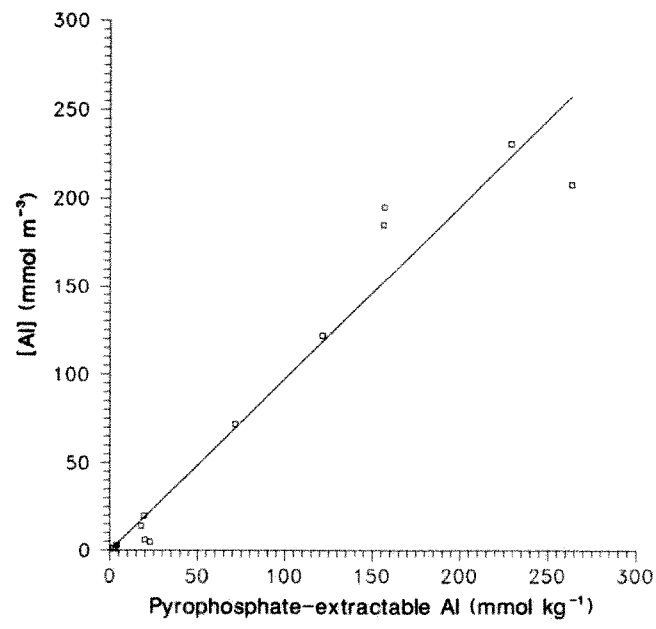

Fig. 2 Equilibrium aluminium concentrations in individual HCl leachates, after 10, 25 and 50 acid additions, as a function of $Na_4P_2O_7$-extractable aluminium. Data refer to all six soil horizons. Equilibrium concentrations of aluminium ([Al]) are significantly correlated ($R^2=0.9466$) with $Na_4P_2O_7$-extractable soil aluminium (Al_{pyro}): $[Al] = -0.60 + 0.98 \times Al_{pyro}$, where [Al] is in mmol m^{-3} and Al_{pyro} is in mmol kg^{-1}.

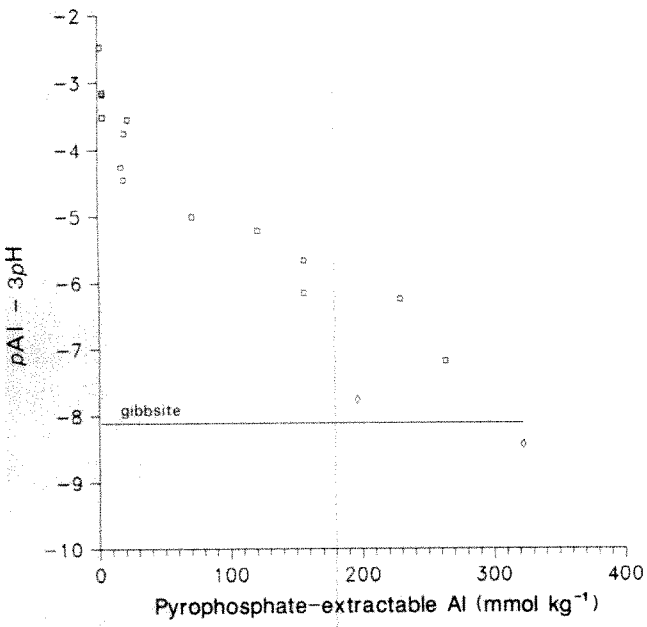

Fig. 3 Values for $p\mathrm{Al} - 3p\mathrm{H}$ in equilibrium leachates as a function of $Na_4P_2O_7$-extractable aluminium. Leachates are from all soil samples after 10, 25 and 50 HCl additions (squares). For the samples of the two podzol Bhs horizons values of the first leachate are also given (diamonds). Aluminium activities were calculated using the chemical equilibrium program ALCHEMI (ref. 18). For gibbsite we used $pK = -8.11$ (ref. 13).

introduction of acid rain produces a drastic change in the naturally occurring podzolization process.

The mobility of aluminium in the Hubbard Brook soils is significantly lower than in the Dutch soils (Table 1), because of higher soil-solution *p*H values, which is due, in turn, to a lower acid load and higher mobilization rates of base cations[15].

The current rapid depletion of organic aluminium in the rooting zone of many acid, sandy soils is irreversible on a timescale of decades or centuries. Because aqueous aluminium concentrations are in equilibrium with solid-phase alumino-organics, depletion upon continued acid deposition will inevitably lead to a reduction in dissolved aluminium concentrations. At the same time, soil-solution *p*H values, which are currently buffered in the *p*H range 3.5–4.2 by dissolution of aluminium[3] (J.M. *et al.*, preprint), may drop to values just below 3. Such dramatic changes in the soil solution chemistry of the rooting zone may have significant ecological consequences. Therefore, depletion of solid-phase organic aluminium and the associated changes in the chemical composition of soil solutions should be incorporated in current soil-acidification models.

We thank the Dutch State Forest Service and Mr W. A. M. Rijken for making available the research sites. This study was supported in part by the EEC and by the Netherlands Technology Foundation (STW).

A new picture of the Moho under the western Alps

ECORS–CROP Deep Seismic Sounding Group*

The Moho—the boundary between crust and mantle first discovered by A. Mohorovicic[1]—is the main seismic marker in the continental lithosphere. The seismic nature of this interface, in terms of its position, topography, smoothness and continuity, may preserve imprints of the regional geodynamic evolution of the lithosphere. Here we report the results of a wide-angle seismic profiling experiment across the western Alps, which allows us to draw a cross-section of the Moho across this mountain belt. A tight sampling of this deep reflector shows abrupt changes in its depth and dip. The root zone of the chain (the zone of maximum crustal thickness) is well defined, with a 55-km-deep crust–mantle boundary. The Moho under the western Po plain is also clearly seen, and a shallow reflective structure is mapped under the Briançonnais zone in the 25–30 km depth range. This structure, if interpreted as lower-crustal or upper-mantle material, would support the hypothesis of a flaking of the lithosphere under the western Alps[2,3].

To prepare the layout of the vertical reflection line through the western Alps that formed the basis of the ECORS–CROP project[4,5] in 1986, a preliminary series of experiments[6] was conducted which aimed at mapping very deep interfaces along a cross-section extending from Grenoble (France) to the Po Plain (Italy). One-ton charges were detonated at five places (Fig. 1) and part of the recording array—low-frequency geophones and autonomous recorders—was deployed along fan profiles, a method which had already proved successful in other orogenic belts[7–9]. The fan radii were chosen so as to coincide with the theoretical maximum amplitude of reflections, corresponding to total reflection, at and beyond a critical distance. The Moho depth was assumed to be ~40 km, with an increase from west to east; the fan radii therefore ranged from 90 to 130 km. Because the velocity is assumed to be constant within the crust, and because each shot-station line is along the local strike of the Alps, no apparent dip of the reflector is expected. Each mirror point (triangles in Fig. 1) can therefore be plotted half-way between the shot-point and the station. With an average station spacing of 4 km along the fans, the reflectors are thus sampled every 2 km.

The fan data were processed to construct two composite cross-sections of the Alpine chain, showing the topography of deep reflectors (Figs 2 and 3). Figure 2*a*, corresponding to shots A, B and C, begins 30 km west of the Belledonne External Crystalline Massif (ECM) and extends through the Briançonnais and Piedmontese zones to the east of the Dora Maira Internal Crystalline Massif (ICM); Fig. 2*b* (shots D and LW) extends from the Gran Paradiso ICM to the Po Plain, intersecting the Sesia–Lanzo zone and the Canavese line, which marks the western limit of the chain. It should be understood that these

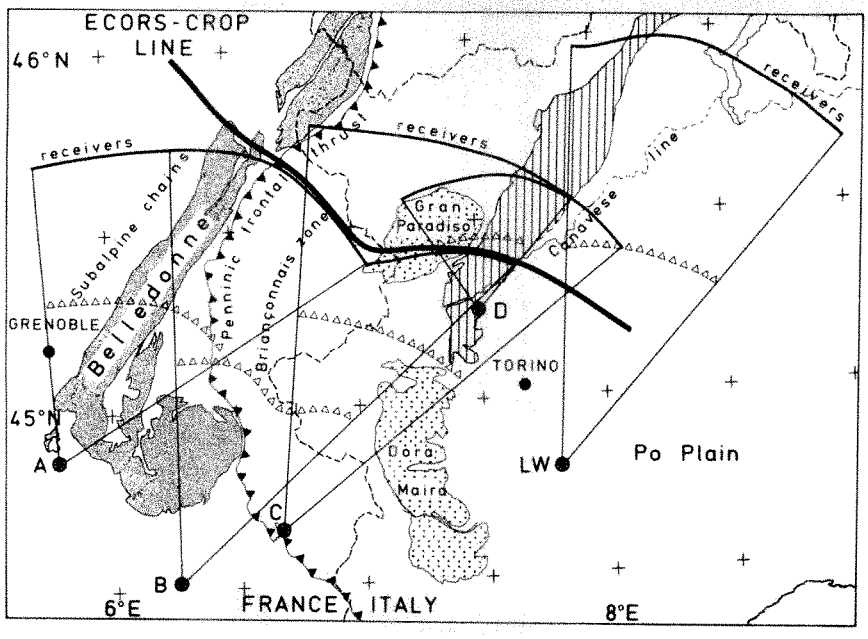

Fig. 1 Position map of the fan layout, showing the 5 shot-points A, B, C, D and LW. Open triangles indicate reflection points used to construct Fig. 2. Shaded area represents external crystalline massifs; dotted area represents internal crystalline massifs; hatched area represents the Sesia-Lanzo unit.

cross-sections combine fans with unavoidable offsets between them; for example, in Fig. 1, mirror points for shot D are shifted northwards by about 50 km relative to those for shot B. For this reason we chose to separate the two northern fans (D and LW) from the three southern ones, to keep a minimum of continuity within a composite cross-section. According to the Bouguer gravity map[10], the deep structures can be assumed to retain a cylindrical geometry for at least the 30-km extension across the section considered here.

On the seismic sections, reflections are picked using a maximum-amplitude criterion together with a correlation between traces. Around the critical distance, the wavelet reflected from the Moho is known to be very energetic, so that it can be identified with the maximum-amplitude signal. The sharpness of the onset of the reflected wavelet varies throughout the section (compare, for example, the two ends of the section in Fig. 2*a*), probably because of a variation in the seismic response of the reflector. Large (~20-km) variations in depth of the Moho marker are evident, and dips reaching 20° and extending over distances of tens of kilometres are observed. In the ECM area (Figs 2*a* and 3), the changes in depth and dip do not occur smoothly, as if by continuous flexure: from being almost horizontal at a depth of 37 km under the sub-alpine massifs and the ECMs, the Moho dips abruptly from 37 km to 55 km at their eastern edge, where the present-day maximum surface relief is found. Towards the innermost parts, under the Piedmontese zone and the Dora Maira ICM, it remains at a more or less constant, deep level of 55 km. The conversion of reflection times to depths depends on the mean crustal velocity, which is here taken to have the value 6.25 km s^{-1}; from previous seismic experiments[11-15], this value is known to be rather constant over this region so that we can assume that the depths thus obtained are accurate to better than 5%.

This deep Moho is overlaid by another seismic marker with high reflectivity (Fig. 2*a*, shot C). The maximum amplitude of the signals from the latter occur at depths of between 25 and 30 km, although it is difficult to determine accurate arrival times for these. Common experience in deep seismic profiling suggests that this reflective zone should be associated with a velocity contrast of more than 1 km s^{-1}, so that it corresponds either to the top of lower-crustal material or to a crust-mantle boundary. Situated at shallow depth and extending westwards beneath the Piedmontese zone and the ICMs as far as the Briançonnais zone, this reflector can be detected only when shooting from C. It acts as a mask which prevents the seismic energy from penetrating deeper, so that from shot-point C no deep Moho

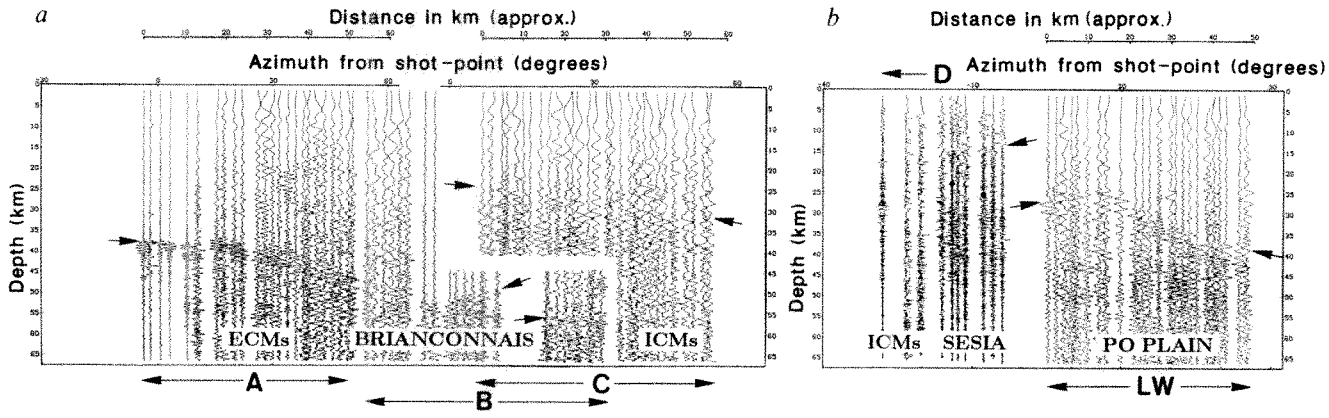

Fig. 2 Two composite cross-sections of the western Alps. *a*, The three fan profiles from shot-points A, B and C (see position on Fig. 1) are combined as a single record-section extending from the Chartreuse sub-alpine massif (far left) to the Dora Maira massif (far right). *b*, This shorter section combines results from shot-points D and LW and extends from the Gran Paradiso massif (far left) to the Po plain (far right). In each trace, the maximum-amplitude signal corresponds to reflection from the Moho. Earlier (shallower) energy arrivals may be ascribed to intracrustal discontinuities. For shot D, recorded at the relatively short distance of 40 km, the late (deep) arrivals are principally transverse S waves rather than reflected waves. Depths are calculated assuming a mean crustal velocity of 6.25 km s^{-1}.

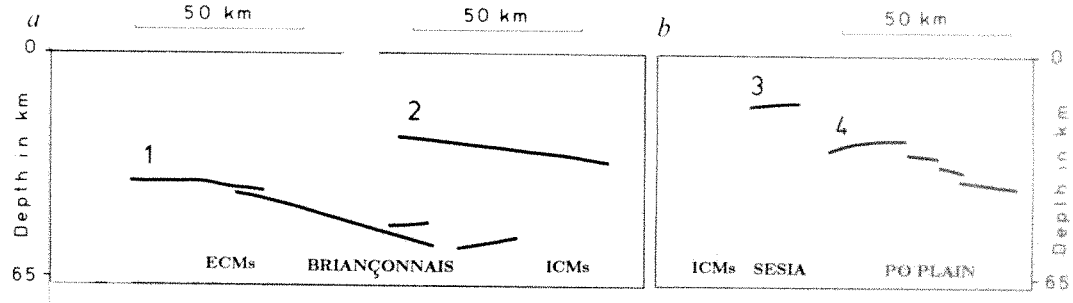

Fig. 3 Schematic line drawings of the profiles revealed by the corresponding seismograms in Fig. 2. (1) Autochthonous deep Moho; (2) Briançonnais reflector; (3) Ivrea body reflector; (4) hinterland (Po plain) Moho. In lithospheric flaking optics, features (2) and (3) trace the imbrication of anomalous upper mantle within the Alpine pile.

could be mapped. From shot-points A or B, however, the deep Moho can be reached, illustrating both the limited extent of this shallow unit and the importance of the shot/recording-array geometry in detecting such a feature.

The hinterland Moho (Fig. 2*b*), more than 35 km deep under the Po plain, where thick Tertiary–Quaternary sequences occur, seems to rise in a stepwise fashion to less than 25 km approaching the Canavese fault zone. Across this zone, there exists a gap in the seismic data, so that one cannot rule out the existence of another uprising of material with high seismic velocities. The Sesia zone is underlain by a strong reflector at a depth of only 13 km, which may correspond to a crust–mantle boundary. However, other deep reflectors in the same area, seen along a complementary longitudinal profile through Sesia, cast doubt on whether the hinterland Moho extends this far west and at such shallow depth; in a zone close to the Lanzo massif, where slices of lower-crustal and upper-mantle material have been brought up to the surface, reflective levels might be rather discontinuous. Nevertheless, the simplest structural scheme is to link the 13-km deep reflector discovered under the Sesia zone to the Po plain Moho further east.

From this wide-angle reflection profiling therefore emerges the first detailed picture of the geometry of the Moho beneath the Alps, incorporating even the innermost zones. Previous experiments[11–15] sampled the Moho too sporadically so that only smooth variations could be mapped. Close-ups of the sections presented here show that such a continuous geometry is not entirely correct, as was previously suggested by a teleseismic prospecting of lithospheric contrasts beneath the Alps[16]. This conclusion results mainly from the high spatial resolution made available by the arrangement of the fans, which provided a 2-km sampling interval of reflectors along the cross-sections.

The shallow reflective level that we have discovered under the Briançonnais zone has never before been mapped, although recently published models of Alpine orogenesis[2] have suggested such a feature. The presence of lower-crustal or upper-mantle material would indicate a tectonic thickening, resulting from previously adjacent eastern lithospheric segments having been thrust onto the western segment (the alternative, internal deformation of the sole crust, is unlikely). This would suggest flaking of the European lithosphere under the western Alps, which is discussed more thoroughly elsewhere[5].

The Ivrea body, an anomalously shallow mantle unit discovered from gravity evidence in early geophysical experiments in the Alps[11], is sampled here from shot-point D, but our experiment is unable to define its exact geometry. It is much too shallow (13 km depth) to be connected directly to the Briançonnais reflector, 30 km under the ICMs. The anomalous upper mantle imbricated within the Alpine crust therefore consists of two distinct units, the Ivrea body and the new unit discovered here.

The fan layout of the experiment proved successful in detecting very deep reflections, and the ECORS–CROP vertical reflection line was able to provide information on upper- and mid-crustal reflectors. Uniting vertical reflection profiling with the more versatile wide-angle reflection method therefore provides the sort of complementary information required to determine the deep structure of such complex orogens as the Alpine chain.

This reconnaissance project was funded by the ECORS (France) and CROP (Italy) national programmes. The participation of numerous field operators, as well as the support and willingness of local authorities at the shot-points, are acknowledged. We thank L. Jenatton for help with the artwork.

Testing the completeness of earthquake catalogues and the hypothesis of self-similarity

Paul A. Rydelek & I. Selwyn Sacks

Department of Terrestrial Magnetism, Carnegie Institution of Washington, 5241 Broad Branch Road N.W., Washington, DC 20015, USA

Self-similarity of the earthquake process is consistent with the observed linear *b*-value relation log $(N) = a - bM$, where N is the number of earthquakes with magnitude M. Deviations from linearity are believed to be due to statistical fluctuations because of the scarcity of events at large M, or from incompleteness because of a detection threshold at small M. Above some magnitude level, all local events are detected, because they exceed the noise background on the seismogram. As magnitude decreases, however, events go undetected as the seismic signal approaches the noise background. Thus more of the smallest events should be logged at night than during the day, because the cultural noise sources and winds are diminished at night, resulting in presumably quieter seismograms. Here we use this day-to-night noise modulation to develop a completeness test for earthquake catalogues; catalogues that indicate no significant modulation are considered complete. We test three catalogues and show that the completeness magnitude can be different from the magnitude at which the *b*-value departs from linearity. In particular, catalogues that show significant deviations in linearity at small M but are otherwise complete, are at odds with the hypothesis of earthquake self-similarity.

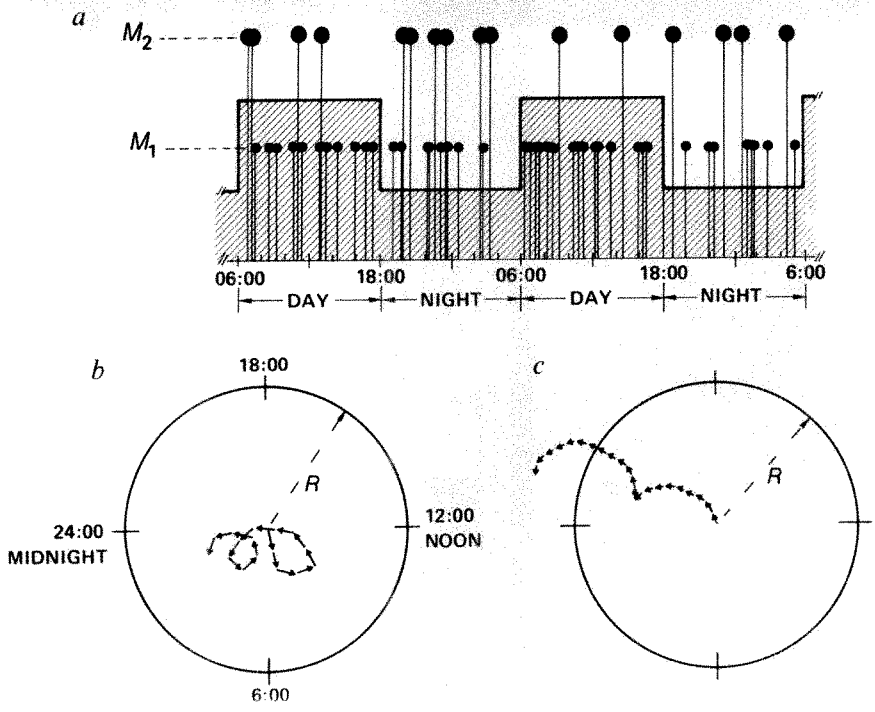

Fig. 1 *a*, An example of day-night noise modulation using a synthetic earthquake sequence of two different-magnitude events which follow Poisson distributions. The larger earthquakes (M_2) exceed the background noise (stippled area), so the phasor plot of these events (*b*) ($N = 16$, $R = 6.9$) shows no bias in the walkout. The smaller events (M_1) are detected only during the night, when the noise background is reduced, so these events show a significant phasor walkout (*c*) ($N = 50$, $R = 12.2$). The circles in *b* and *c* are drawn at the 95% confidence level for an equivalent random walk (Brownian motion). The Poisson rate for the smaller events is 1 event per hour and the *b*-value is 0.5.

Our method of testing for completeness follows one originally proposed by Schuster[1]. The test makes two assumptions about the earthquake process and the seismographic station, namely (1) that earthquakes, at any magnitude level, follow a Poisson distribution, and (2) that the daytime noise level is increased relative to night-time because of cultural activity and wind noise.

The randomly distributed (Poisson) nature of earthquake sequences (with aftershocks removed) is well documented in studies of seismic catalogues[2] but exceptions have been found, namely in a few cases that show modulations of the seismicity from tidal stresses of the Sun and the Moon[3,4], that is, through tidal triggering of earthquakes. A spectrum of the tidal forcing function, however, has negligible power at a period of exactly 24 hours[5], which is the period of the clock used in our test of completeness described below. The only known noise sources with a 24-hour periodicity are cultural and solar thermal effects (such as surface temperatures and winds); thus any daily modulations in the seismicity must be due to these sources. When observed, a modulation implies that some events at the detection threshold are missed during the half-cycle of increased noise, resulting in an incomplete catalogue. Our method of analysis, but with clocks tuned instead to the major tidal components, has been used successfully in studies of tidal triggering of earthquakes[3]. We have ignored the remote possibility of thermally triggered earthquakes, but note that the phase in Fig. 1 could be diagnostic.

Within a given magnitude level, the origin time of a seismic event is used to form a phase (or hour) angle on the local 24-hour clock; thus the catalogue of earthquake times is mapped into a set of earthquake phases. Each phase angle is assigned unit amplitude and then a phasor sum is performed over the set of individual unit phasors. The resulting phasor sum or 'walkout', R, is compared with that expected from a random process. For a set of random phases (that is, earthquakes that follow a Poisson process) the probability of obtaining a walkout larger than R is given by $P_R = \exp(-R^2/N)$. We reject the null hypothesis of randomly distributed earthquake phases when P_R is below some confidence level $(1 - P_R)$. Therefore, if the observed R exceeds some critical radius (a reasonable value is $1.73\sqrt{N}$, corresponding to a 95% confidence level), then the catalogue contains a significant bias in the day-to-night recording of earthquakes in the given magnitude interval and should be classified as incomplete at (and below) this magnitude. The sensitivity of our test is dependent on the number of events. For example, we can detect a 3% incompleteness (worst case) in a 10,000-event catalogue, increasing to 9% incompleteness for 1,000 events.

A simple example of day-night noise modulation is shown in Fig. 1. In this example, all the larger-magnitude earthquakes would be detected as they are clearly above the noise at any time of the day. The phasor walkout formed from this set of earthquakes grows as $\sqrt{N}$ and resembles Brownian motion because the phase angles are random, having been determined from earthquakes that have a Poisson distribution. The smaller-magnitude earthquakes are also Poisson-distributed but because more are detected when the noise is reduced (that is, during local night) they tend to form a non-random pattern with average alignment biased towards night-time hours. In this example, our test indicates that the larger-magnitude events are completely catalogued but the smaller ones are not. Of course, variations in noise levels in real catalogues are never as clear-cut as shown in our example, but the persistent bias introduced by any day-night noise modulation should eventually be detectable in catalogues of longer duration. As soon as the modulation becomes significant, the catalogue is shown to be incomplete. Intrinsic in the test is the confirmation that the modulation exists, because it becomes visible at lower magnitudes. The test provides an objective answer to the question of completeness, makes no assumptions about the linearity of the *b*-value curve, and allows one to set a confidence level on catalogue reliability to answer further questions regarding the underlying nature of the earthquake process.

Other problems arising in catalogues are the result of bursts of earthquake activity, such as swarms and aftershocks, which produce sections of highly non-random, and in worst cases almost linear, phasor walkout. There are algorithms for identifying (and removing) aftershocks[2], but we choose simply to ignore all shocks occurring more frequently than at twice the average hourly earthquake rate for the catalogue (again within a given magnitude interval).

We demonstrate our completeness test with catalogues of crustal earthquakes (0–30 km deep) obtained from three

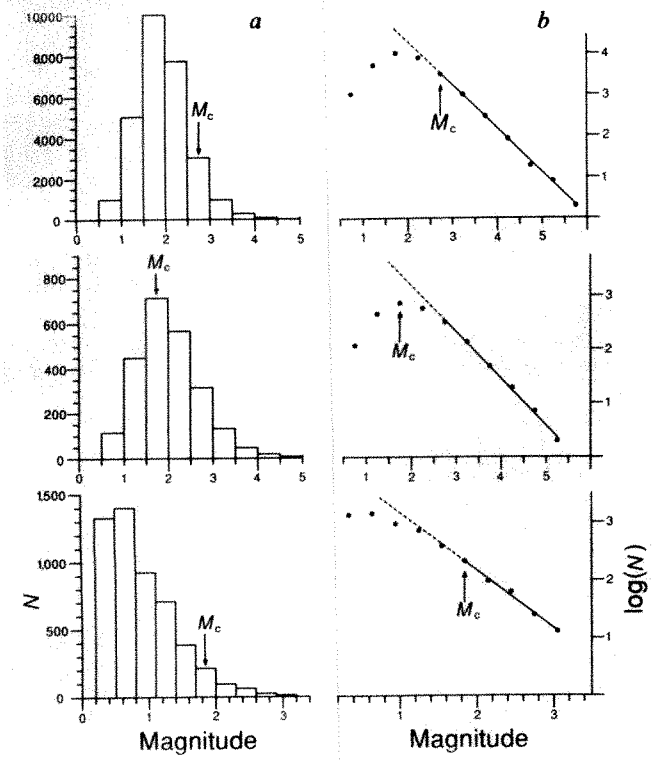

Fig. 2 Plots of *a*, the number of events N, and *b*, $\log(N)$, within given magnitude intervals for catalogues HAW (*a*), KMU (*b*) and POZ (*c*). The *b*-values are, respectively, 1.06, 0.87 and 1.00, and were determined using the points fitted with the solid straight line; the dashed line is an extrapolation using $\log(N) = a - bM$. Arrows mark the smallest magnitude at which a catalogue is complete, based on the phasor walkouts in Fig. 3.

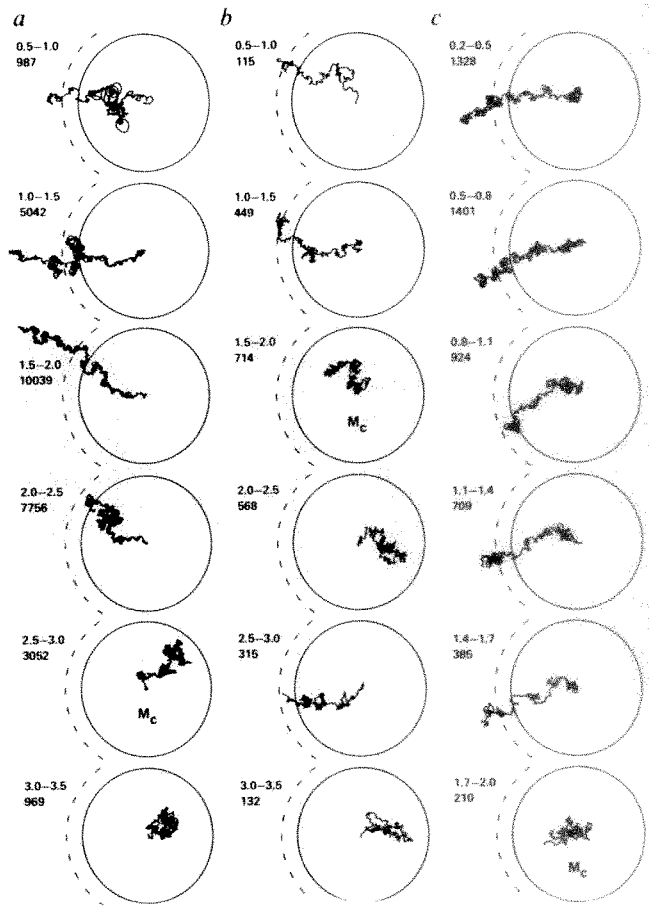

Fig. 3 Phasor sum plots for the catalogues HAW (*a*), KMU (*b*) and POZ (*c*). The numbers in each frame are the magnitude intervals and the numbers of events. The plots are time-oriented as in Fig. 1*b*, and scaled such that the confidence levels are drawn with constant radii (solid = 95%; dashed = 99% confidence level). A catalogue whose walkout does not span a chosen confidence level is considered complete at that level; thus M_C is the smallest magnitude of completeness (95%) for each catalogue in this figure.

different seismic arrays: (HAW) Island of Hawaii, coverage of ~80 km radius, 41 stations, 1977–1985; (KMU) southeast corner of Hokkaido, Japan, ~50 km radius, ~9 stations, 1976–1987; and (POZ) Phlegraean Fields near Pozzuoli, Italy, ~3 km radius, 22 stations, 1983–1984. Plots of the number of events versus magnitude are shown in Fig. 2 for these catalogues. The difference in the peak position and shape of the curves between the larger arrays HAW and KMU, and the smaller, concentrated array POZ is readily apparent (Fig. 2*a*), but *b*-values are still near unity (Fig. 2*b*), in general agreement with the concept of self-similarity. Notice also that catalogue POZ is divided into smaller magnitude intervals because of the increased sensitivity but limited-magnitude bandwidth of this array. The phasor walkouts as a function of magnitude for the three catalogues are shown in Fig. 3 for the same magnitude intervals used to construct Fig. 2. The smallest magnitude interval at which each of the catalogues passes the completeness test (95%) is labelled as M_C. We are confident that the data set at (and above) M_C is complete but we make no claims about the degree of incompleteness of the data below this point.

Catalogue HAW shows a departure from linearity in the *b*-value plot at ~1/2 magnitude below M_C. We assume that this non-linearity is caused by the loss of events below the threshold, rather than having the same cause as the violation of the linear relation seen for larger magnitudes.

In POZ, an obvious non-linear departure starts at ~1 magnitude below M_C and rolls off rather gradually. This catalogue is collected from a relatively small region compared with KMU and HAW and is therefore susceptible to very localized noise sources such as commuter traffic on a road during certain times of the day. Although this selective increase in background noise may have a small effect on the *b*-value curve, say a ~10% deficit, it is certainly within the range of detectability by our completeness test. POZ exemplifies a catalogue that does not show significant departures from linearity even though it fails the completeness test. In fact, when the number of events peaks, our test attains maximum sensitivity, in contrast to a *b*-value plot which has minimum sensitivity at peak N.

The KMU catalogue shows a highly significant fall-off in the number of smaller events even though the catalogue is apparently complete. Taylor and coworkers[6,7] reached the same conclusion in a recent study of this catalogue. We believe that this points to an important deviation in the common lore of linear *b*-value curves and the idea of the self-similar earthquake process.

We thank the following (and their colleagues) for kindly allowing us to use their catalogues: (HAW) R. Koyanagi, Hawaiian Volcano Observatory, (KMU) T. Takanami, Hokkaido University, and (POZ) R. Scarpa, University of Rome.

Distribution of seamounts in the North Atlantic

David Epp* & N. Christian Smoot†

* National Science Foundation, 1800 G Street NW, Washington, DC 20550, USA
† Bathymetry Division, US Naval Oceanographic Office, NSTL, Mississippi 39522, USA

The paucity of multi-narrow-beam bathymetric data in the ocean basins has meant that previous studies[1–8] of seamount distribution and size have relied on wide-beam echo sounder data and small amounts of Seabeam multi-narrow-beam data. Since 1967, however, the US Naval Oceanographic Office has been collecting multi-narrow-beam bathymetric data[9–14]. Here we use an extensive collection of such data to locate over 800 seamounts in the North Atlantic. We find that ridge crest-generated seamounts are formed only between Iceland and the Hayes fracture zone, where there are contributions of plume material to the mid-ocean ridge plumbing system. It appears that in the slow-spreading North Atlantic an injection of plume material into the ridge plumbing system is necessary for the formation of seamounts at the ridge crest.

We use the term seamount for all circular or elliptical features of volcanic origin, regardless of size, including those where flanking rift zones or slumping alter the basic circular or elliptical shape. The multi-beam data we studied are contoured at 10-fathom intervals (1 fathom = 6 feet). In some areas, such as the rift valley of the northern Reykjanes ridge[15], we were able to locate seamounts that had a relief of the order of 20–30 fathoms. Because of the rough block-faulted nature of the ridge, however, it is impossible, on the ridge flanks, to separate seamounts this small from the general ridge-flank tectonic fabric. To be certain that we counted only volcanic features, we have limited our study to seamounts that have a relief greater than 50 fathoms. Although there are undoubtedly smaller volcanoes that we did not count, the smaller seamounts, where detectable, have the same general distribution as those higher than 50 fathoms.

Figure 1 shows the location of seamounts in the North Atlantic with a relief greater than 50 fathoms. Excluding the Lesser Antilles, there are 810 seamounts. The blank areas reflect the lack of seamounts; the general distribution pattern is unlikely to be affected by the lack of data. We estimate that the total number of seamounts with heights greater than 50 fathoms is unlikely to be underestimated by more than 10% as a result of incomplete data coverage. Sediment thickness in the North Atlantic is highly variable[16] and it is likely that smaller volcanoes have been buried. For example, in the area between the New England and Corner seamounts there are a number of small seamounts that are probably the tops of larger seamounts buried by sediments from the Sohm abyssal plain. The pattern of sediment distribution in the North Atlantic does not, however, correspond to the distribution of seamounts shown in Fig. 1, indicating that the general seamount distribution pattern is unlikely to be affected by sediment burial.

Morgan[17,18] and Duncan[19] have described the traces of the major hotspots in the North Atlantic. Figure 1 shows the distribution of seamounts in these traces, in addition to several smaller traces. Madeira and Canary hotspots generated the Milne and Newfoundland seamount groups, respectively, before crossing to the east side of the Mid-Atlantic Ridge (MAR). The Canary hotspot is probably responsible for the cluster of seamounts located at 38°–41° N and 15°–18° W. Both of these hotspots passed through the Madeira–Tore Rise and Horseshoe seamount areas[19]. In addition, the Africa/Eurasia plate boundary passes through the Horseshoe seamount area, so it is not clear which of the seamounts in this area were generated directly by the hotspots and which might be due to hotspot interaction with the plate boundary. The trace of the Azores hotspot is uncertain. According to Morgan[17] the hotspot would have been near Coruna 'seamount' at about 60 Myr ago and would have followed the Azores–Biscay rise to its present position. (Coruna is located at 44° N 14° W, but it does not appear to be volcanic and is not plotted in Fig. 1.) The trace was undoubtedly affected by interactions with the MAR and the Iberia–Africa/Eurasia plate boundary. Great Meteor hotspot generated the New England and Corner seamounts before crossing the MAR and generating the seamounts in the vicinity of Cruiser and Great Meteor. The hotspot was near the ridge crest during the formation of the Corner seamounts, ~75 Myr ago, and remained near the crest until ~38 Myr ago, when it crossed to the east side of the ridge between the Oceanographer and Hayes fracture zones[19]. The group of seamounts between the New England seamounts and Bermuda can be attributed to Verde hotspot[19], but is is not clear if the three small groups located along 26–27° N between 20° and 28° W are also due to Verde. Also, the origin of the three clusters west of the Cape Verde islands is unclear. The Researcher seamounts and the Barracuda/Researcher ridge form chains of volcanoes that are co-polar with the other hotspot traces in the western North Atlantic and are thus probably due to weak hotspots. The North Brazilian ridge is a line of seamounts in the Ceara abyssal plain that also may be a hotspot trail and may be related to either the Bathymetrists or Sierra Leone hotspots. The Charcot 'seamounts', located along 45° N between 10 and 15° W, do not appear to be volcanic in origin and are probably an expression of the extinct Iberia–Africa/Eurasia plate boundary.

The interaction of hotspots with mid-ocean ridge (MOR) systems has been discussed extensively[20–26]. Morgan[27] suggested that the hotspot did not have to be directly under the MOR for this interaction to occur; conduits for the flow of plume material to the MOR plumbing systems could be maintained as the MOR moved away from the hotspot. Schilling[28,29] has elaborated on this model and, on the basis of extensive sampling of the crest of the MAR, proposed that along-ridge geochemical gradients about ridge-centred hotspots can be attributed to incompatible-element-rich magmas which rise as plumes or blobs beneath the hotspots and mix with the incompatible-element-depleted asthenosphere that normally feeds the spreading ridge. In the North Atlantic, Schilling[29] identifies hotspot contributions from Jan Mayen, Iceland, 45° N, Azores, 35° N and 14° N. The K_2O, La/Ti and La/Sm anomalies associated with Iceland extend south of Iceland to about 60° N. The strontium anomaly reaches a minimum at 60° and appears to increase toward the Charlie–Gibbs fracture zone. The Iceland helium anomaly, however, extends south to the Charlie–Gibbs fracture zone (see Schilling[29], Fig. 3 and Plate 8B). There is a narrow geochemical anomaly associated with the Charlie–Gibbs fracture zone. Between the Charlie–Gibbs and Kurchatov fracture zones there is a broad geochemical anomaly centred at 45° N. There appears to be a narrower superimposed anomaly at 43° N. These anomalies cannot be attributed to known hotspots. If they are due to separate hotspots, then these hotspots did not generate seamount chains or other bathymetric expressions. The geochemical anomalies caused by the Azores hotspot extend between the Kurchatov and Hayes fracture zones. There is a small contribution at 35° N between the Pico/East Azores and Hayes fracture zones that probably comes from Great Meteor hotspot[30]. South of the Hayes fracture zone there is no plume component except for a small anomaly at 15° N, for which Barracuda/Researcher hotspot may be responsible.

There is a first-order correlation between the distribution of seamounts along the MAR and the hotspot contribution to MAR magmas. Seamounts are formed only between Iceland and the Hayes fracture zone where there are contributions of plume magma to the MAR plumbing system. South of the Hayes fracture zone there are no ridge crest-generated (RCG) seamounts and only the small geochemical anomaly at 14° N. The

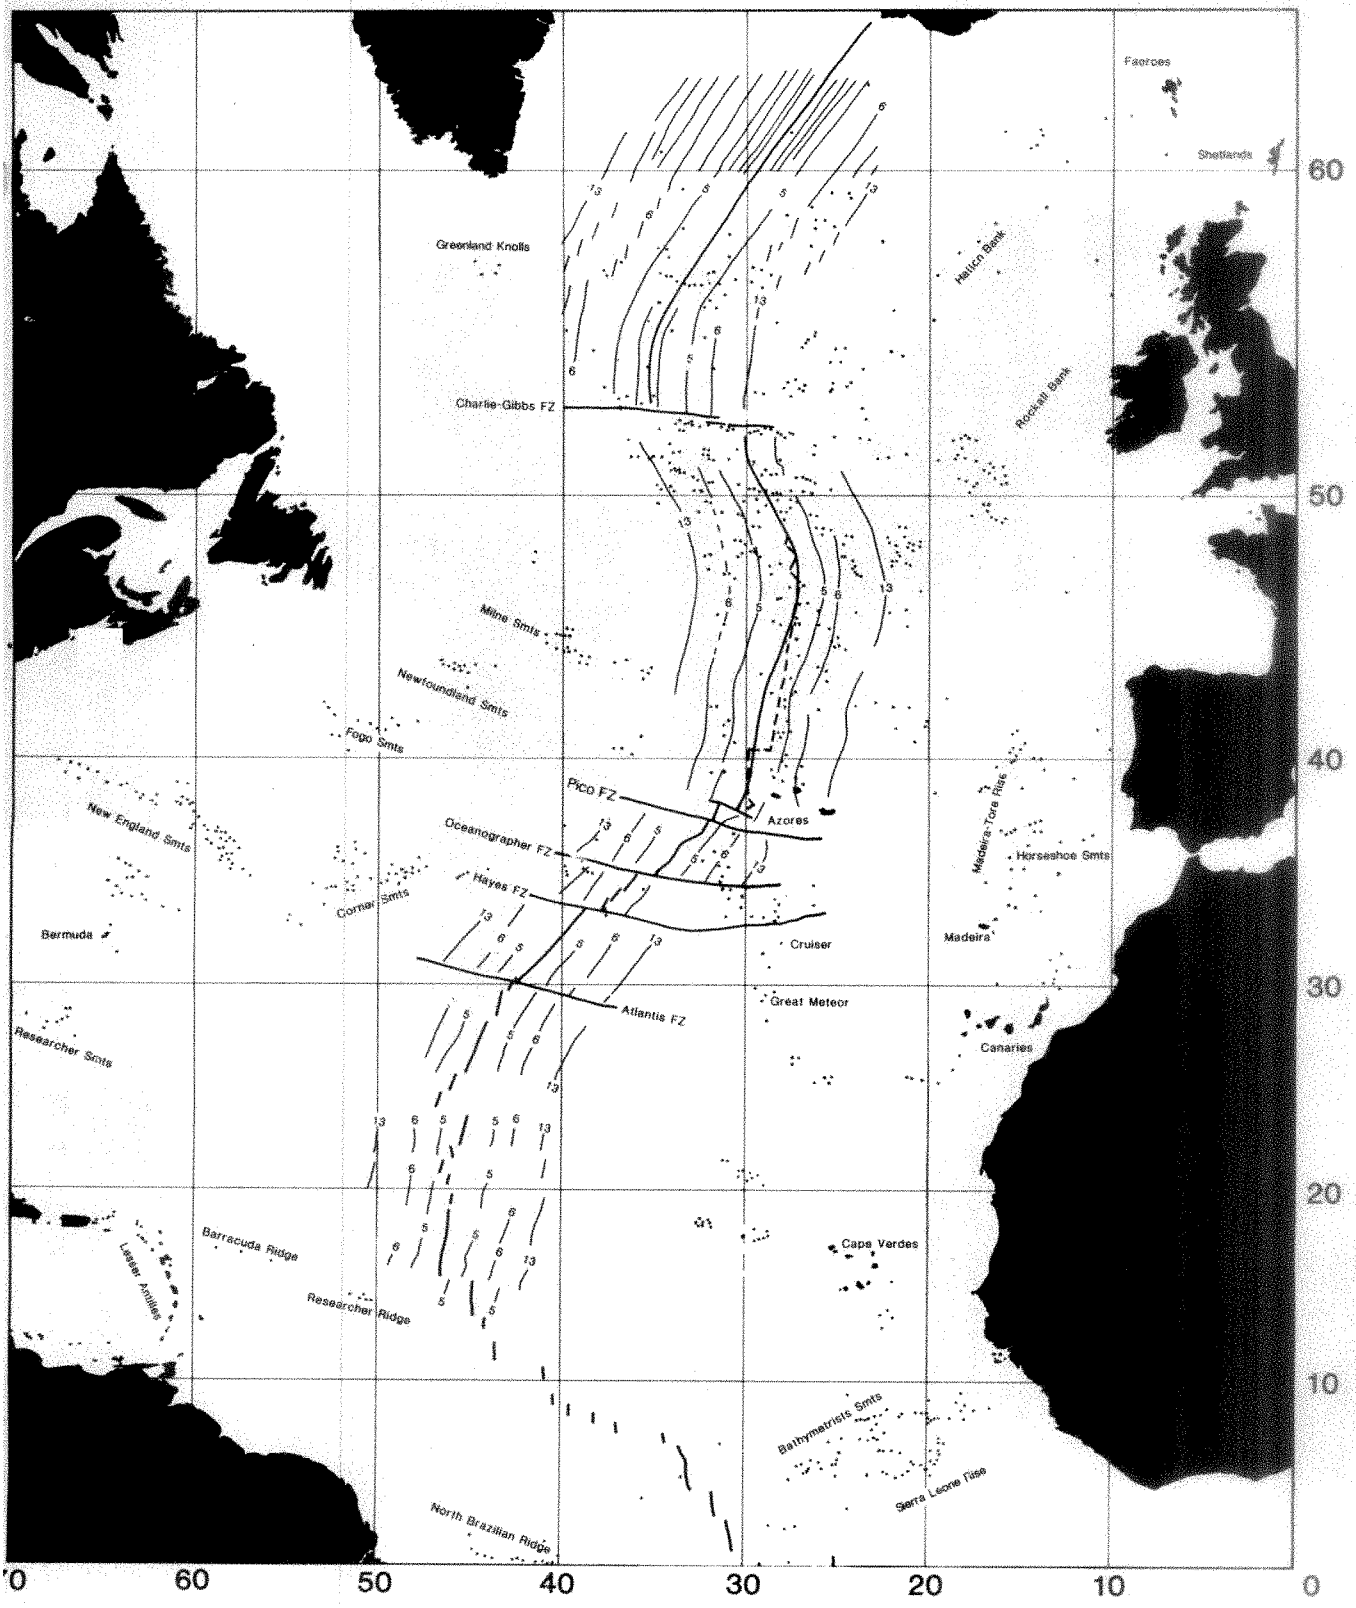

Fig. 1 The locations of seamounts in the North Atlantic with heights greater than 50 fathoms (shown as dots). Magnetic lineations are from S. Cande (personal communication). The dashed line shows the location of the topographic high between the Charlie–Gibbs fracture zone and the East Azores fracture zone; it does not correspond to anomaly zero.

atter is relatively recent[31] and it may be that the Barracuda/Researcher hotspot has contributed only enough material to the plumbing system to affect the geochemistry but not enough to generate seamounts. The detailed relationships between the distribution of seamounts and plume contributions to the MAR plumbing system are more complex. In addition to the variation in seamount numbers along the MAR, it is obvious from Fig. 1 that seamount generation varies with time and is not always symmetrical about the ridge axis. Figure 2 shows the number of seamounts for every one degree of latitude in 0–10, 10–20 and 20–35 Myr time windows (corresponding to magnetic anomalies 1, 5, 6 and 13) for the east and west sides of the

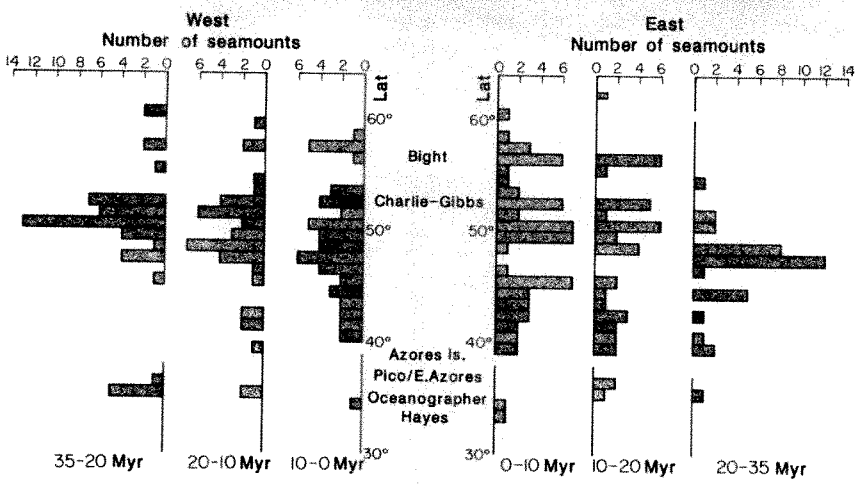

Fig. 2 The number of seamounts plotted against latitude in 0–10, 10–20 and 20–35 Myr time windows (corresponding to magnetic amomalies 1, 5, 6 and 13) for the east and west sides of the Mid-Atlantic Ridge. The latitudes of fracture zones and the Azores islands are indicated. Where the base line of the graphs is omitted there is insufficient data to provide an accurate count of seamount numbers.

MAR. The greatest concentration of seamounts occurs between the Charlie-Gibbs and the latitude of the Azores islands. This presumably reflects the strong contribution of plume material to this section of the MAR by the 45° N and Azores hotspots. The distribution of seamounts on the west side of the ridge suggests that these hotspots started contributing material to the plumbing systems at ~45 Myr in the section of ridge just south of the Charlie-Gibbs, and that the interaction is no older than ~20 Myr at the present latitude of the Azores. On the east side of the ridge the seamount distribution indicates an older and more complex interaction. There is a significant cluster of seamounts on crust older than anomaly 13 between 47° and 49° N, an absence of seamounts between the ridge crest and anomaly 6 at 46° to about 49° N, and a large cluster just west of the Ireland continental shelf at 49° to 52° N. This complexity in seamount distribution is most probably related to the reorganization in plate boundaries in this area and the interaction between the ridge plumbing system and the hotspots. Between ~60 and 35 Myr, King's trough, the Azores-Biscay rise and the Charcot 'seamounts' formed the plate boundary between the Iberia-Africa and Eurasia plates[32,33]. The Azores hotspot was moving along the Azores-Biscay rise during this time[17]; however, the location (or existence) of the 45° N hotspot during this time is uncertain as it did not leave a bathymetric trace.

The seamounts between the Azores and the Hayes fracture zones may be due to the plume contribution from Azores hotspot or from Great Meteor hotspot. Morgan[18] suggested that the group of seamounts between Cruiser and Great Meteor were formed directly by Great Meteor hotspot and that the cluster of seamounts between Cruiser and the Oceanographer fracture zone was formed by the interaction of the hotspot with the MAR. Great Meteor hotspot is nearly 900 km from this section of ridge crest[28], so its contribution to the MAR plumbing system is probably small. The geochemical anomaly associated with the Azores, on the other hand, extends past the Pico/East Azores fracture zone to the Hayes. The offset across the Pico/East Azores fracture zone decreases significantly between anomalies 6 and 5. In the vicinity of the Azores the ridge crest appears to be 'pulled' toward the Azores (as indicated by the dashed line in Fig. 1), and although there is a distinct bathymetric expression of the fracture zone east and west of the ridge crest, there is no distinct bathymetric offset of the present ridge crest. Thus, there may be no blockage of flow at the Pico/East Azores fracture zone. On the other hand, the offset on the Oceanographer fracture zone is 120 km and the offset on the Hayes is 80 km[34]. It is not clear why material flows past the Oceanographer but not past the Hayes, unless the volume of flow is nearly depleted by the time it gets to the Hayes.

With the exception of the helium anomaly, and perhaps the strontium anomaly, the geochemical anomalies associated with Iceland hotspot do not extend south of 60° N[29]. There i however, no offset in the MAR at this latitude that would indica a blockage of flow. There are very few seamounts along th Reykjanes ridge between Iceland and 60° N whereas there ar a significant number between 60° N and the Charlie-Gibb fracture zone. Seamounts have been generated along this sectio of the MAR for the past 35 Myr, although the seamounts aroun the periphery of Rockall bank and the cluster between th southwest corner of Rockall and the Charlie-Gibbs may hav been formed at the ridge crest before 35 Myr. The section fror 60° N to Charlie-Gibbs is the one section of the MAR wher seamounts are formed without a strong hotspot signal in th geochemistry.

The line of seamounts along the Bight fracture zone (show in Fig. 1 as an east-west line of seamounts at 57° N) is responsibl for the peak in the 0-10 Myr and 10-20 Myr windows in Fig. 2 It seems likely that the fracture zone provided easy conduits fo these volcanoes[2,7], although it is obvious that fracture zones ar not necessary for seamount formation in the North Atlantic There must be local perturbations to the plumbing system o other zones of weakness in the crust that control the locatio of the majority of the seamounts.

The first-order correlation of RCG seamounts with the geo chemical data indicates that an injection of plume material i necessary for the formation of RCG seamounts. This suggest that in a normal spreading situation the MAR plumbing syster has only enough pressure to lift magma to the top of the crust which follows if decompression melting is the only source o magma. An injection of plume material overpressurizes th plubing system; some of the excess pressure is released by th formation of seamounts, and some may be released by th formation of thick crust. The seamounts act like piezometers ir the plumbing system and allow an estimation of the minimum overpressure resulting from the plum contribution. Seamount with heights of ~1,500 fathoms are associated with the Charlie-Gibbs fracture zone, requiring an overpressure of ~42 MPa. Fo comparison, this is about half of the pressure in the Kilauea summit reservoir before the 1960 eruption on Kilauea's lowe east rift zone[35]. The North Atlantic is thought not to have a steady-state magma chamber, and Schilling[29] suggests that small discontinuous, transient magma chambers may be more likely in slow-spreading ridges. If so, the overpressure almost certainly varies with distance along the ridge and with time, although it is not clear how these variations are reflected in the distributio of seamounts. The formation of seamounts between 60° N and the Charlie-Gibbs could be explained if the Iceland plume contribution pressurizes the MAR plubing system as far south as the Charlie-Gibbs, but the plume material flows only as fa as 60° N. A similar phenomenon is observed in Kilauea, where pressure changes in the summit reservoir are propagated down

the east rift zone before magma moves along the rift zone.

The model presented above suggests that the processes responsible for the generation of seamounts on the MAR are relatively simple, although the detailed variations in plume contributions and seamount distribution suggest that factors such as the volume of plume material, conduit geometry, location and offset of fracture zones, and the timing of plate reorganizations and hotspot interactions must also be considered. The North Atlantic may constitute the slow-spreading endmember of these processes, and it is not clear how, or if, these processes are applicable to faster spreading ridges.

Geochemical evidence for invasion of Kilauea's plumbing system by Mauna Loa magma

J. M. Rhodes*, K. P. Wenz*, C. A. Neal†, J. W. Sparks* & J. P. Lockwood†

From the beginning of the study of Hawaiian volcanism there has been controversy over possible relationships between the neighbouring active volcanoes Mauna Loa and Kilauea[1–5]. Seismic activity, thought to reflect upward migration of magma, reveals that the magmatic plumbing systems apparently converge at depth to form a broad funnel within the mantle[6]. Although on rare occasions they have erupted concurrently, the brief historical eruptive record appears to show that when Kilauea is most active, Mauna Loa is in repose and vice versa, suggesting that they may be competing for the same magma supply[5,7]. Petrological, geochemical and isotope data, however, require a diametrically opposite conclusion. Distinct differences in major-element, trace-element and isotope compositions of lavas are regarded as compelling evidence that the two volcanoes have separate magmatic plumbing systems, supplied by parental magmas from physically and geochemically distinct mantle sources[8–13]. Here we present preliminary geochemical data which show that in the past 2,000 years Kilauea has erupted a spectrum of lava compositions resembling historical Kilauea lavas at one end and Mauna Loa lavas at the other. We discuss the cause of this diversity, and speculate that magma from Mauna Loa may have invaded Kilauea's 'high-level' magmatic plumbing system.

Most surface lava flows on Kilauea are younger than 1 kyr (refs 14–16). To examine more of the recent prehistoric record, we sampled successive flows exposed in the walls of two pit craters, Kilauea Iki and Pauahi[17]. Kilauea Iki is close to the summit caldera; Pauahi is about 6 km down Kilauea's upper east rift zone. Age control for these flows depends in part on palaeomagnetic results[14,15], and in part on the age of the Uwekahuna Ash, a thin phreatomagmatic deposit derived from Kilauea's summit[4,15,18,19]. The Uwekahuna Ash is well exposed in the walls of Pauahi crater, about 45 m above the floor, but is not present in the walls of Kilauea Iki. From ^{14}C measurements, Lockwood (personal communication) infers an age of 2.1 kyr for the ash. Using this age and palaeomagnetic results[14,15], we infer that lavas exposed in the walls of Pauahi crater range in age from greater than 2.1 to ~0.4 kyr, and those in Kilauea Iki range from 1.5–2.0 kyr to ~0.4 kyr.

Compositional differences between historical Kilauea and Mauna Loa lavas, which have been thoroughly documented[8–13], are readily apparent from the ratios of Zr/Nb, Zr/Y and La/Yb (Figs 1 and 2), and from the averaged data summarized in Table 1. Previous studies propose that, at a given MgO content, prehistoric Kilauea lavas are more 'Mauna Loa-like' than their historical counterparts[9,20]. Disputing this conclusion, Easton and Garcia[21] found that Hilina Formation lavas older than 22 kyr exposed on Kilauea's south flank are compositionally close to modern lavas. Our data show that Kilauea lavas erupted over the past 2.0 kyr vary significantly in composition, particularly in abundances and ratios of the incompatible elements. In Fig. 1, historical lavas (AD 1823–1987) are characterized by Zr/Nb ratios of $\sim 10 \pm 1$, whereas prehistoric lavas are more varied and display a distinctly bimodal distribution with maxima at ~11 and 14. The lavas with Zr/Nb ratios of ~14 are similar in both major- and trace-element composition to Mauna Loa lavas (Figs 1 and 2; Table 1). Prehistoric Kilauea lavas, with lower Zr/Nb ratios, show a range of compositions from those broadly resembling modern Kilauea ($Zr/Nb < 11$) and Hilina Formation lavas, to others with compositions intermediate ($Zr/Nb = 11–12.5$) between those of historical Mauna Loa and Kilauea lavas (Table 1; Fig. 2).

In Pauahi crater, the Mauna Loa-like flows are restricted to a few thin flow units immediately above the Uwekahuna Ash, and close to the top of the section (Fig. 2). The remainder of the section comprises flows with compositions closer to, but not identical with, modern Kilauea lavas[17]. Flows on the southern wall of Kilauea Iki crater grade from Kilauea-like compositions near the base, through intermediate compositions, to Mauna Loa-like flows in the middle of the section, and back through intermediate compositions to Kilauea-like flows at the top (Fig. 2)[17].

To improve temporal control, we have also analysed samples of nine eruptive units from Kilauea's summit area, with ages

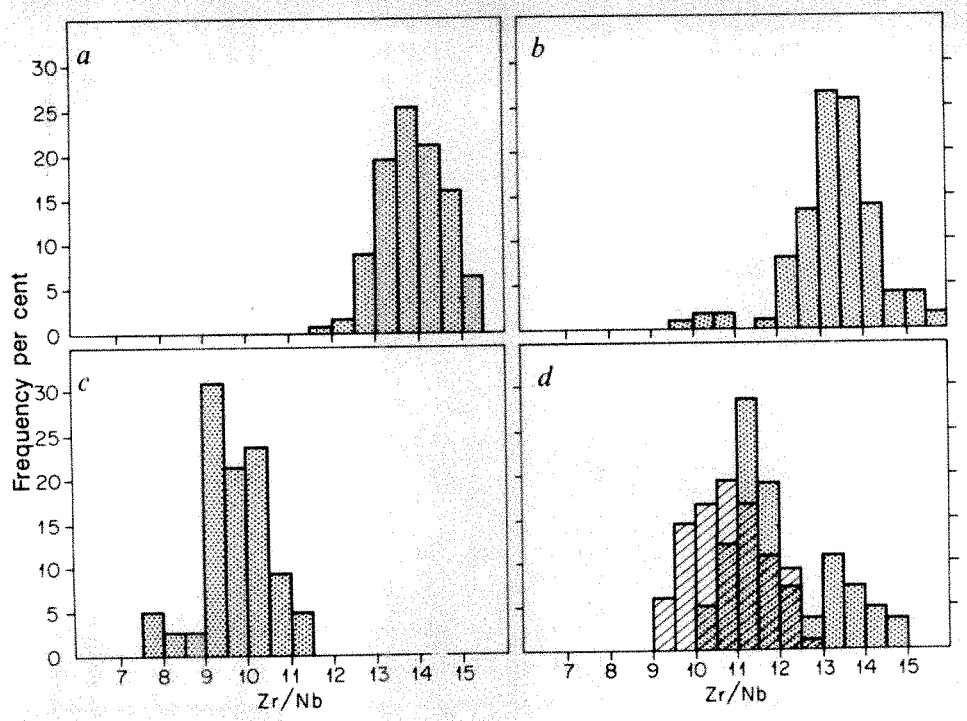

Fig. 1 Histograms of Zr/Nb ratios for historical (AD 1843–1984; $N = 137$) (*a*) and prehistoric (<30 kyr; $N = 130$) (*b*) Mauna Loa lavas, and historical (AD 1823–1987; $N = 42$) (*c*) and prehistoric (*d*) Kilauea lavas. Note the greater range and bimodal distribution for recent prehistoric (<2 kyr) as compared with historical Kilauea lavas. Hilina Formation lavas (≥22 kyr) (hatched bars in *d*; $N = 41$) have Zr/Nb ratios that are close to those of historical lavas[21].

The data have been normalized to a constant 7.0% MgO by addition or subtraction of olivine (Fo_{88}). Lavas that depart from an olivine-controll trend have been excluded from the compilation. Major- and trace-elements Rb, Sr, Nb, Zr and Y were determined by X-ray fluorescence (XR at the University of Massachusetts. Rare-earth elements and Hf were determined by instrumental neutron activation analysis (INAA) in the laborato of F. A. Frey at Massachusetts Institute of Technology. Data are from this study and refs 13, 17, 22 and 23. s.d., Standard deviation.

* Numbers refer to those analysed by XRF and INAA respectively.

‡ Chondrite-normalized.

constrained by ^{14}C dating to between ~0.25 and 1.1 kyr. With the exception of the youngest flows (<0.4 kyr), which resemble modern Kilauea lavas in composition, all these flows show compositional variations similar to the pit crater flows. Figure 2 and Table 1 show very clearly that there is a continuum of compositions for prehistoric Kilauea lavas ranging from those that resemble modern Kilauea lavas to those that resemble historical Mauna Loa flows. More have intermediate compositions than have either Kilauea-like or Mauna Loa-like compositions. Figure 3 illustrates a possible evolutionary scenario for the distribution of lavas of varied composition in Kilauea's summit and upper east rift zone.

Most Mauna Loa lavas are restricted in composition, clustering at the intersection of an olivine-controlled trend with a trend for more differentiated lavas. Typically, they contain ~6.8–8.0% MgO (refs 22, 23). Rhodes[23] attributes this uniformity to eruption from a continuously replenished shallow magma reservoir. The Mauna Loa-like lavas on Kilauea also share these characteristics, with MgO content between 6.6 and 8.6%. In contrast, Kilauea-like and intermediate lavas are more variable, ranging from differentiated basalts (5.5% MgO) to picrites (21% MgO)[17].

The presence on Kilauea of flows with compositions that strongly resemble magma processed through Mauna Loa's shallow plumbing system might reflect flooding by Mauna Loa flows of the adjacent, and lower, Kilauea shield[15]. Such flows would have travelled over 20 km, originating on Mauna Loa's northeast rift zone. Far-travelled flows are typically dense tube-fed pahoehoe or thick aa units; the map relations, flow thickness, texture and vesicularity of these flows, on the other hand, indicate that they did not travel far, but were erupted on Kilauea. Furthermore, in our extensive investigations of Mauna Loa, no flows with intermediate compositional characteristics have been found throughout over 30 kyr of eruptive history[9,23].

This raises several intriguing possibilities. The magmas supplying Kilauea over the past 2 kyr may have been derived directly from the mantle either by partial melting of a mixed, multi-component mantle source, or by mixing of magmas from two or more distinct sources. Alternatively, they may have been supplied indirectly, as would be the case had magma from Mauna Loa invaded Kilauea's magmatic plumbing system.

The heterogeneous nature of the mantle source for Hawaiian volcanism is well established[11,13,24,25]. However, it is mainly during the evolutionary stages of a volcano's history[5], typically over time periods of a million years or more, that major temporal changes in lava composition occur. With the exceptions of Koolau[26] and Kahoolawe[27], the tholeiitic shield-building stages[5] of most individual Hawaiian volcanoes are characterized by relatively uniform and distinctive geochemical features[28]. Our unpublished data for Mauna Loa show that prehistoric lava compositions have remained comparatively homogeneous for over 30 kyr (Fig. 1). Similarly, on Kilauea, lavas of the Hilina Formation (>22.5 kyr) remained relatively uniform in composition over perhaps as long as 50 kyr (ref. 21). We suggest, therefore, that compositional fluctuations in the mantle source within a time frame of less than 2.0 kyr are unlikely.

Although partial melting of a heterogeneous mantle source cannot be ruled out, we are persuaded otherwise by two key observations. First, Mauna Loa-like lavas erupted on Kilauea have all the compositional attributes of lavas processed through Mauna Loa's plumbing system. Second, these and intermediate-composition lavas first appear stratigraphically above the Uwekahuna Ash. The Uwekahuna Ash is thought to have been produced by a major explosive eruption associated with caldera collapse, which was itself initiated by massive magma drainage along one of the two rift zones[4,15,18,19]. Evidence for extensive magma movement and drainage along Kilauea's east rift zone before the explosive 1924 summit eruption has been well documented[4,5]. The possible magnitude of this process is illustrated by the recent discovery of voluminous (2-km^3), relatively young

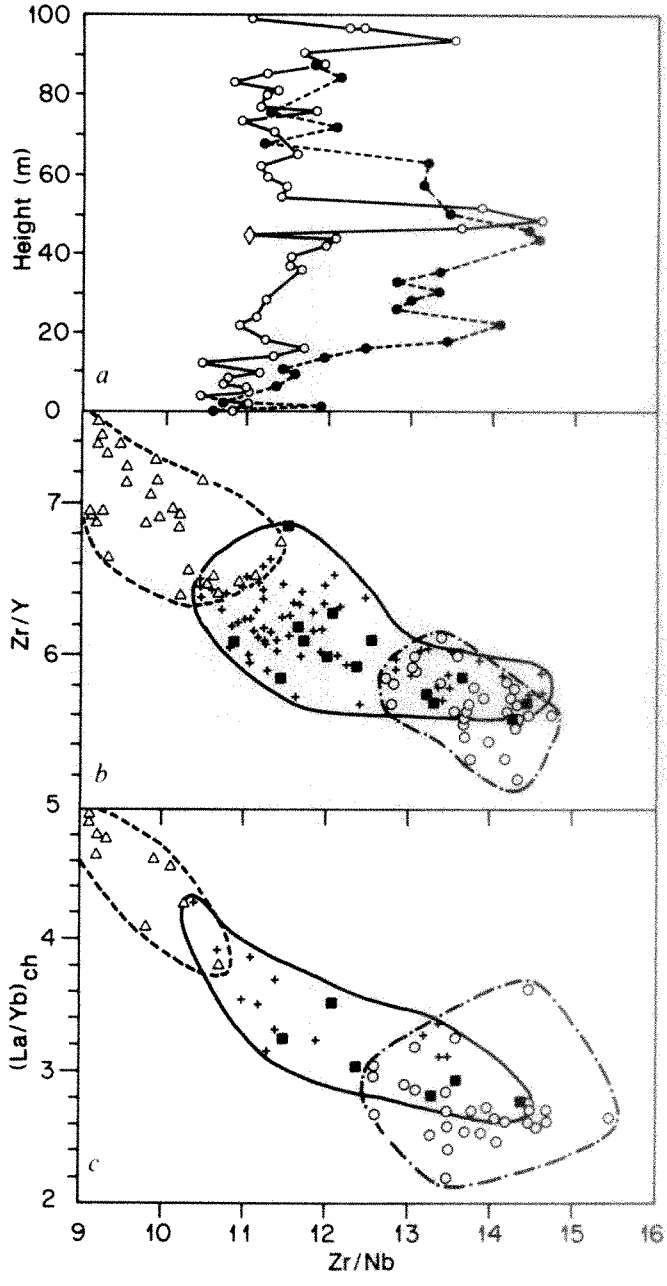

Fig. 2 *a*, Variation in Zr/Nb ratio with stratigraphic height in the walls of Pauahi (open circles joined by solid line) and Kilauea Iki (filled circles joined by dashed line) pit craters. Note the presence of the Uwekahuna Ash (open diamonds) at 45 m in the Pauahi section; this ash is presumed to be below the pit crater floor in the Kilauea Iki section. *b*, Zr/Y versus Zr/Nb ratios for Kilauea Iki and Mauna Loa lavas. Field for prehistoric Kilauea lavas shown as a solid line. ■ Prehistoric Kilauea lavas (200–1,100 yr BP) with ^{14}C age control; + Pauahi and Kilauea Iki lavas; △, Historical Kilauea lavas, field shown as dashed line; ○ Historical Mauna Loa lavas, field shown as dot-dashed line. *c*, Chondrite-normalized La/Yb versus Zr/Nb ratios for Kilauea and Mauna Loa lavas. Key is the same as for *b*. In *b* and *c* prehistoric Kilauea lavas reveal a range in composition from historical Kilauea to historical Mauna Loa.

lava flows emanating from the submarine extension of Kilauea's east rift zone, which are thought to represent such magma drainage[29].

We speculate that, following the voluminous magma drainage responsible for the Uwekahuna event, magma stored in the adjacent shallow plumbing system of Mauna Loa may have invaded Kilauea's evacuated plumbing system. Some of this

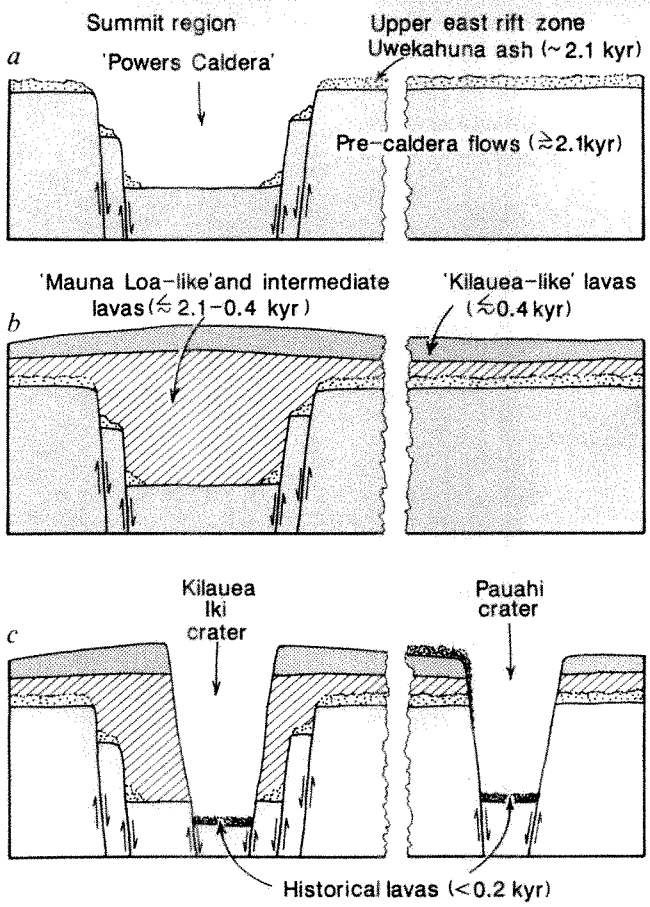

Fig. 3 Schematic representation of the inferred evolution of the geochemical variations in Kilauea summit and upper-east-rift-zone lavas over the past 2.1 kyr following the eruption of the Uwekahuna Ash. *a–c* represent successive configurations in time. The Uwekahuna Ash is a widespread phreatomagmatic base-surge deposit, derived from Kilauea's summit. It is thought to be associated with the collapse and formation of the ancestral 'Powers Caldera'[4,15,18,19]. Lavas erupted before the formation of the Uwekahuna Ash and the Powers Caldera resemble modern Kilauea lavas in composition. Subsequent eruptions produced lavas that are more Mauna Loa-like in composition, or have compositions intermediate between those of modern Kilauea and Mauna Loa lavas. The greater thickness of these lavas in Kilauea Iki pit crater, in contrast with their restricted occurrence in Pauahi pit crater, is attributed to filling of the Powers Caldera and to the greater eruptive frequency in the summit region of the volcano compared with the upper east rift zone during this period. Only over the past 0.4 kyr have lavas resembling historical Kilauea lavas been erupted.

magma would retain its compositional identity in discrete magma batches and would subsequently be erupted. Much of the invading magma, however, would mix with residual pockets of Kilauea magma distributed throughout the plumbing system to produce magma with intermediate compositions. Table 1 and Fig. 2 show that such a mixing scenario is plausible. Subsequently, as Kilauea's magma supply recovered, eruptions of strictly Mauna Loa-like lavas would become increasingly rare and lavas of intermediate composition would predominate. Once initiated, such a magmatic connection might remain active for some time.

This model is at present based primarily on geochemical arguments. Seismic or geodetic observations show no evidence for currently active magma conduits between the two volcanoes, but there is tentative geophysical evidence for a fossil shallow magmatic connection. Aeromagnetic data display a roughly linear zone of high magnetic intensity from the vicinity of Kilauea caldera to the upper north-east rift zone of Mauna Loa, and have been interpreted as indicating an interconnection between the two volcanoes[30,31]. Furthermore, a recent seismic tomography study by Ho-Liu and Johnson (personal communication) identifies a sub-horizontal zone of high attentuation between the two volcanoes at a depth of 4–10 km that is roughly coincident with the aeromagnetic anomaly. As it is not presently active seismically, it clearly does not reflect a current magma conduit, but it could be the 'fossil' relict of the magma conduit required by our model.

We thank D. A. Clague and H. B. West for their thorough reviews. This work was supported in part by a faculty research grant from the University of Massachusetts, and in part by the NSF.

Fitness costs of gestation and lactation in wild mammals

T. H. Clutton-Brock, S. D. Albon & F. E. Guinness

Large Animal Research Group, Department of Zoology, University of Cambridge, Downing Street, Cambridge CB2 3EJ, UK

Like a number of plants[1,2], some mammals commonly produce more progeny than they can afford to rear, terminating investment in some or even all of their offspring once the resources available for breeding are known[3–5]. Adaptive interpretations of juvenile wastage rely on the argument that the costs of gestation are small compared to those of feeding offspring. Though energetic evidence supports this conclusion[6], it is unsafe to assume that the relative costs of gestation and lactation to the mother's survival and future reproductive success follow the same pattern because lactation commonly coincides with the period of maximum food availability. Controlling for individual variation, we show that in wild red deer (*Cervus elaphus* L) any costs of gestation to the mother's subsequent survival and reproductive success are slight compared to those of lactation.

Reproductive histories of 283 individually recognizable hinds were collected in a food-limited population on the Isle of Rhum, Inner Hebrides between 1971 and 1987 (ref. 7). In each year of

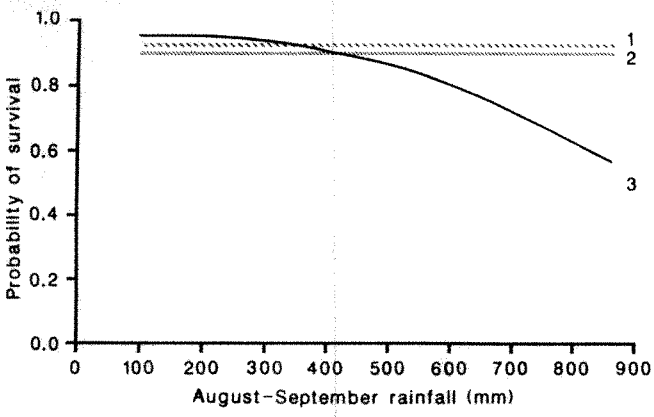

Fig. 1 Logistic curves illustrating the probability of a hind surviving a winter following a year in which she was (1) barren, (2) had produced a calf but lost it shortly after birth, and (3) reared a calf until weaning, are plotted against August-September rainfall (mm), which depresses survival in this population ($\chi^2 = 23.3$, $P < 0.001$) (ref. 9). These curves are standardized for hind age and values shown are for 12-year-olds (quadratic in age: $\chi^2 = 78.1$, d.f. = 2, $P < 0.001$). N (hind-years) = 1,479. Coefficients in the exponential equation (see text) are: (1) 3.107 − 0.000907 (August-September rainfall); (2) 2.444 − 0.000177 (August-September rainfall); (3) 3.563 − 0.003427 (August-September rainfall).

their lives, hinds were allocated to four categories. The first category consisted of those hinds that produced no calf (barren). Previous evidence suggests that when a hind was barren she had usually failed to conceive[7] and consequently did not suffer the costs of either gestation or lactation. The second category consisted of hinds that lost their calf within three months of its birth. In practice, 90% of the 156 such calves died within their first two weeks of life. In these years, mothers consequently avoided most of the energetic cost of lactation. The third category consisted of hinds whose calf had died between 4 and 12 months of age. 80% of the 204 calves allocated to this category died between February and May aged 9–12 months. Finally, the fourth category consisted of hinds that had successfully raised their calf to at least 12 months of age. We investigated relationships between the period for which the calf survived and four components of the mother's fitness: her survival during the winter following the calf's birth; her probability of producing a calf in the year after the calf's birth (fecundity); and the birth date and weight of her subsequent calf, both of which are known to affect calf survival[8]. In this population, high rainfall in August and September depresses the growth of grass and reduces food availability at the onset of winter, with the result that both fecundity and over-winter survival fall after wet autumns[9]. Our analysis consequently allowed for annual variation in rainfall in late summer.

Differences in fitness components between barren hinds and those whose calves died soon after birth should reflect the costs of gestation, whereas differences between mothers whose calves died soon after birth and hinds whose calves survived for six months or more should reflect the costs of lactation. Estimates of the costs of reproduction based on comparisons of this kind can underestimate the actual costs of breeding because, despite their greater energetic expenditure, mothers of superior phenotypic quality sometimes show higher survival rates or superior reproductive performance when compared to inferior phenotypes that did not breed in the previous year[10,11]. To minimize this problem, we compared the subsequent reproductive performance of the same hinds following years when they had been barren, had produced calves but lost them soon after birth or had reared calves to over six months.

In these analyses we included a factor to remove the effects of individual differences between mothers and restricted our sample to 145 females born between 1967 and 1978 to ensure that we included reasonable samples of breeding attempts for each individual. Generalized linear models[12] were used to estimate the probability of the mother's survival or fecundity in relation to her reproductive status in the previous year[13]. The dependent variables were binary (survive = 1, die = 0; fecund = 1, not fecund = 0) and must be related to any explanatory variable (such as summer rainfall) in a nonlinear way. A logistic model[14] was used to relate a particular transformation of the probability of survival or breeding for each individual (= the logarithm of the odds against dying or failing to breed) to a linear combination of explanatory variables. Logistic regressions were of the form:

$$P(Y_i =) = \frac{\exp(A + B_1x_{i1} + B_2x_{i2} + B_3x_{i3} + B_4x_{i4} + B_5x_{i5})}{1 + \exp(A + B_1x_{i1} + B_2x_{i2} + B_3x_{i3} + B_4x_{i4} + B_5x_{i5})}$$

where A, B_1, $B_2, \ldots, B_5$ = constants, x_{i1} = August-September rainfall (mm), x_{i2} = previous reproductive status, x_{i3} = reproductive status by rainfall interaction, x_{i4} = age (years), x_{i5} = age^2 and $i = 1, 2, 3, \ldots, N$ hind-years. Offspring birth weights and log-transformed calving dates were examined using an analysis of variance.

The fitness costs of gestation were evidently slight compared to those of lactation. In all years, the survival of barren females did not differ from those whose calves died during their first summer ($\chi^2 = 0.403$, NS). Except in years when late summer rainfall was unusually low and food availability in autumn was unusually high, both these categories of hinds were more likely to survive than mothers whose calves survived until weaning ($\chi^2 = 17.002$, $P < 0.001$, see Fig. 1; reproductive status by rainfall interaction: $\chi^2 = 6.046$, $P < 0.05$).

The subsequent fecundity of hinds did not differ between years when they had been barren and years when they had produced calves but lost them shortly after birth ($\chi^2 = 2.045$, NS). In contrast, their chances of calving were reduced after years in which they had suffered the costs of lactation (barren and early calf loss versus calf reared to >6 months, $x^2 = 292.21$, $P < 0.001$, see Fig. 2) and this difference increased with rainfall

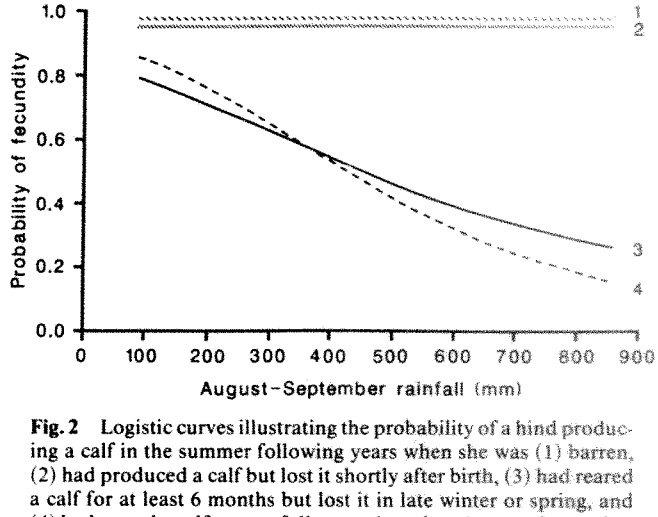

Fig. 2 Logistic curves illustrating the probability of a hind producing a calf in the summer following years when she was (1) barren, (2) had produced a calf but lost it shortly after birth, (3) had reared a calf for at least 6 months but lost it in late winter or spring, and (4) had reared a calf successfully, are plotted on August-September rainfall, which affects fecundity in this population ($\chi^2 = 29.1$, $P < 0.001$) (ref. 9). These curves are standardized for three variables that affect fecundity in this population: winter temperature ($\chi^2 = 12.2$, $P < 0.001$), values shown are for mean December-February daily temperature (4.5 °C); hind age (quadratic in age, $\chi^2 = 32.0$, d.f. = 2, $P < 0.001$), values shown are for 12-year-old hinds; and individual identity ($\chi^2 = 298.3$, d.f. = 134, $P < 0.001$), set here to the median individual. Coefficients in the exponential equation (see text) are (1) 3.728 − 0.000285 (August-September rainfall); (2) 3.319 − 0.000055 (August-September rainfall); (3) 1.637 − 0.003205 (August-September rainfall); (4) 2.160 − 0.004745 (August-September rainfall).

Table 1 Mean calving dates and offspring birth weights of red deer hinds

	Subsequent calving date		Birth weight of next calf (kg)	
Barren	5 June	NS	6.614	*
Calf produced but dies soon after birth	3 June		7.029	
		***		***
Lactating:				
Calf reared for at least 6 months but died between 6 and 12 months	14 June	NS	6.300	NS
Calf survives to 1 year old	14 June		6.466	

Mean calving dates and offspring birth weights of hinds following years in which they had been barren, produced a calf but lost it shortly after birth, reared a calf for at least 6 months but lost it between 6 and 12 months, and reared a calf which survived to one year. Means were standardized to the average individual and average year (1979 for calving date and 1978 for birth weight). In the case of offspring birth weight, means were adjusted for differences in calf sex ratio and the table shows values for males, which are born 0.38 kg heavier than females. NS, not significant; *, $P < 0.05$; ***$P < 0.001$.

in late summer (reproductive status by rainfall interaction, $\chi^2 = 13.1$, $P = 0.001$). Similarly, the subsequent calving date of hinds did not differ between years when they had been barren and years when they had produced calves but lost them shortly after birth ($t = 1.14$, NS), whereas on average they calved and, presumably, conceived ten days later when their previous calf survived to weaning ($t_{436} = 7.61$, $P < 0.001$; see Table 1). This change probably represented an appreciable cost, for a calf's chances of surviving the first year of life declined by 1% per day[15].

Finally, hinds produced heavier calves after years when they had been barren or lost their calves shortly after birth than following years when they had reared calves into the winter ($F_{2,286} = 5.517$, $P < 0.001$; see Table 1). However, hinds produced heavier calves following years when they had produced but lost calves than following those when they had been barren ($t_{102} = 2.04$, $P < 0.05$), presumably because failure to breed was associated with poor body condition and this had an effect on the hind's reproductive performance the following season.

Our results thus confirm that in food-limited populations the fitness costs of gestation are slight compared to those of lactation. It may often be to the advantage of females to produce more offspring than they can usually rear and subsequently to reduce the number of offspring to a level that they can support. This may explain why, in many species, juvenile survival declines more rapidly with resource shortage or with rising population density than fecundity[16].

We thank the Director of the Nature Conservancy Council for permission to work on Rhum; the Council's staff on the island and in Inverness for their support; SERC, NERC and Royal Society for financial support; and David Brown, Andrew Laurie and Paul Harvey for comments or advice.

The potential role of pathogens in biological control

Michael E. Hochberg

Department of Pure and Applied Biology,
Imperial College at Silwood Park, Ascot, Berkshire SL5 7PY, UK

It is now well established that pathogens such as viruses, fungi, bacteria and protozoans can have profound effects on the dynamics of their invertebrate host populations[1]. Theoretical[1,2] models of invertebrate host–pathogen interactions which assume uniform structure of the pathogen population may reasonably explain the oscillatory behaviour observed in some systems[3], but do not adequately describe the existence of more constant populations found in other host–pathogen interactions[4–7]. An examination of the literature relating to these relatively stable systems suggests that the common thread is the eventual transmission of some of the more protected, longer-lived stages of the pathogen occurring in reservoirs, such as the soil[4,5], host cadavers on trees[8], or the live host itself[7]. In this letter, I propose a new theoretical model which incorporates this population structure and accounts for the range of dynamics observed in natural systems. In particular, I show that host populations may be regulated to low and relatively constant densities if sufficient numbers of pathogens are translocated from pathogen reservoirs to habitats where transmission can occur. An understanding of pathogen reservoirs may be of value in the design of biological control programmes and may greatly increase the effectiveness of pathogens as biological control agents.

Models of invertebrate host–pathogen interactions often assume that the transmissibility and lifespan of the pathogen does not differ between pathogen individuals, or stages[1,2]. In nature, however, pathogen populations are far from uniform, because heterogeneities can exist in their spatial and genetic composition[9]. Models which assume homogeneity in pathogen populations have been used to explain the periodic cyclic behaviour of some forest Lepidoptera species[2,3], but the biological features of the pathogen responsible for these oscillatory dynamics (namely high pathogenicity and long-lived stages) are also characteristic of some systems in which the pathogen regulates its host to low and relatively constant densities[5,8,10].

The model presented here (Fig. 1) considers a more realistic structure of the pathogen population than earlier models by dividing the pathogen into two distinct subpopulations, one transmissible and short-lived, and the other non-transmissible and long-lived. For example, in the spruce sawfly, *Gilpinia hercyniae*, the transmissible stages of its nuclear polyhedrosis virus reside on the surface of spruce needles where they are exposed to vagaries of the environment, and are thus highly vulnerable to removal or to mortality[8,11]. Alternatively, stages of the virus can reside in more protected and remote habitats, such as under the bark of the trees, in the upper layers of the soil or in the cadavers of virus-killed hosts[8]. Stages in these 'reservoirs' can only cause infections if they are somehow translocated to the surface of the spruce needles by abiotic and biotic agents such as wind, rain, birds or the live host itself[8,12]. Although an obvious simplification of the real system, this scenario captures the essential dichotomy found in many invertebrate herbivore–pathogen interactions[5,8,13–17].

For the purposes of this study the invertebrate host is assumed to have continuous and overlapping generations, but the underlying results of the model also hold true for host taxa with discrete and non-overlapping generations. In addition, for the clarity of this presentation, the following assumptions are made[1]: (1) the risk of infection to a given host increases linearly with the density of the transmissible pathogen; (2) the production of pathogen stages in the host individual is directly proportional to the average lifespan of the infected host; (3) the infection is invariably lethal; (4) secondary infections are rare or do not

occur at all; and (5) the direct transmission of protected stages to susceptible hosts does not occur. Relaxing these assumptions does not change the basic conclusions of this study.

The dynamics of the host–pathogen interaction are described in terms of four differential equations which capture, in a general way, population processes which are similar to those described above in the invertebrate herbivore-pathogen scenario. These equations are for the density of susceptible hosts (X), infected hosts (Y), transmissible pathogen stages (W) and non-transmissible stages (Q) (Fig. 1): $dX/dt = (a_0 - b)X + a_1 Y - \beta XW$; $dY/dt = \beta XW - (\alpha + b - a_2)Y$; $dW/dt = \theta_1 Y - (\mu + \lambda)W + \nu Q - \phi\beta XW$; and $dQ/dt = \theta_2 Y - (\rho + \nu)Q + \lambda W$. Here a_0 and b are the per capita birth and death rates of susceptible hosts. Infected hosts give birth to either healthy or infected offspring at per capita rates of a_1 and a_2, respectively. The transmission parameter is β, and when infection takes place an average of ϕ stages are removed from the transmissible subpopulation of the pathogen. Once infected, the host can succumb either to natural causes of mortality (b) or to disease-related death (α). As the number of pathogen stages produced per infected host is assumed to be directly related to the average lifespan expected of the infected host[1,2] (that is, $1/(\alpha + b)$), the release of infective stages into the transmissible subpopulation and the reservoir can be represented by the steady states of $\theta_1 Y$ and $\theta_2 Y$ respectively. The transmissible stages die at a per capita rate μ or are translocated at a constant per capita rate of λ to the reservoir.

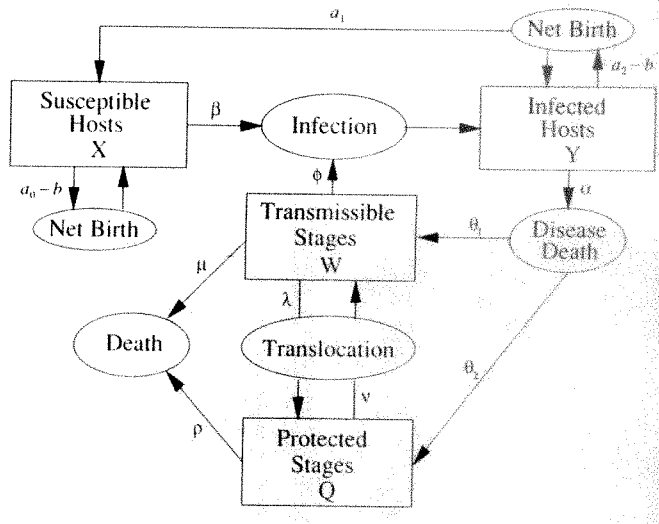

Fig. 1 Diagrammatic flow chart of transitions and rates in the interactions of susceptible hosts (X), infected hosts (Y), exposed, transmissible stages of the pathogen (W), and protected, non-transmissible stages (Q).

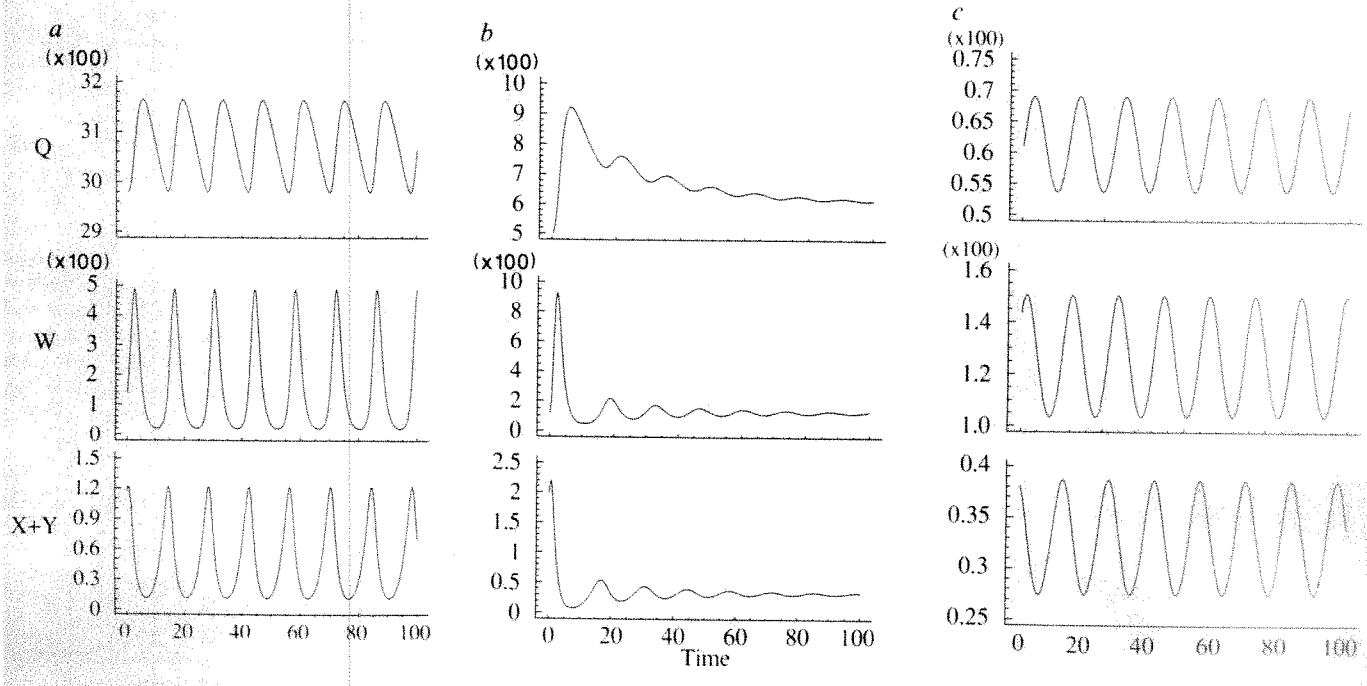

Fig. 2 Examples of population behaviour of total hosts ($X + Y$), transmissible pathogen stages (W) and protected stages (Q) for three different rates of flow of pathogen stages from the protected to the transmissible pathogen subpopulations. *a*, Low rates of flow ($\nu = 0$) resulting in oscillatory populations; *b*, intermediate rates of flow ($\nu = 0.04$) resulting in constant populations; *c*, high rates of flow ($\nu = 0.4$) giving rise to oscillatory populations. The effect of the pathogen reservoir on the host's dynamics can be intuitively understood as follows. First imagine a situation in which pathogen stages are not translocated from the reservoir to the transmissible subpopulation (corresponding to $\nu = 0$). The dynamics of the interaction are similar to those found by Anderson and May[1,2]: persistent oscillations with a period determined to some extent by the rate of liberation of pathogen stages into the transmissible subpopulation (θ_1) and the average lifespan of transmissible stages ($1/(\mu + \lambda)$). Add to this an intermediate flow of stages from the reservoir to the transmissible subpopulation. Now, at peak populations of the transmissible pathogen, stages are being translocated to and stored in the more protected habitats. At times when the transmissible stages are sparse, the release effects of the reservoir result in a net flow of stages to the transmissible subpopulation. Thus, the storage and release capacities of the reservoir tend to 'buffer' the transmissible subpopulation of the pathogen through time, resulting in constant populations of both host and pathogen at equilibrium. If the flow from the protected to the transmissible subpopulation is too strong, then the two pathogen subpopulations effectively become a single entity and the host and pathogen interact in much the same way as they did in the first scenario (that is, oscillatory populations). The important difference is that the greater input of pathogen stages into the transmissible subpopulation has the effect of depressing the host population to lower levels than in the first case (compare Fig. 2*a* and *c*). Parameters common to all three simulations are $a_0 - b = 0.5$; $a_1 = 0.2$; $\beta = 0.005$; $\phi = 1$; $\alpha + b - a_2 = 1$; $\theta_1 = 10^3$; $\theta_2 = 0$; $\lambda = 0.2$; $\mu = 1$; and $\rho = 0.001$.

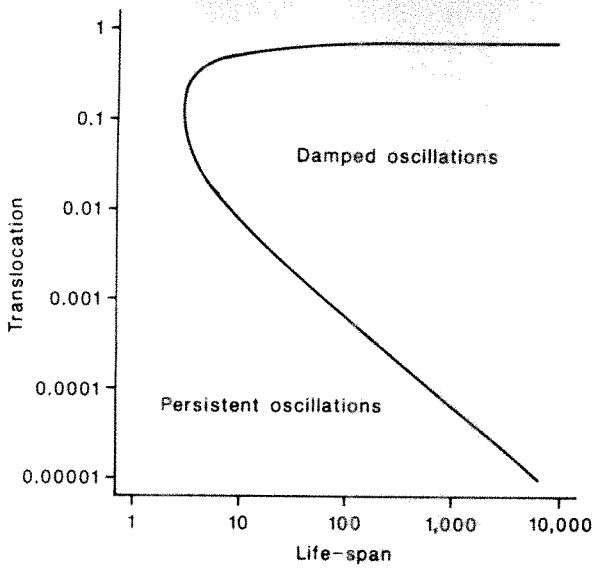

Fig. 3 Population dynamics as determined by the average lifespan of pathogen stages in the reservoir $1/\rho$, and the rate of translocation from the reservoir to transmissible subpopulation ν. Two types of population behaviours occur: oscillatory (unshaded) and constant (shaded) trajectories. Although the boundaries of oscillatory and constant populations will depend to some extent on the values of the other model parameters, there is a simple linear relationship between the logarithms of $1/\rho$ and ν through most of the parameter space. Estimation of these two crucial parameters[25,26] can be made from measurements of the rate of translocation of the pathogen from the reservoir to the transmissible subpopulation (ν) and the average duration of the activity of the pathogen in the reservoir ($1/\rho$ or $1/(\rho+\nu)$). Anderson[27] has found that if the extent of artificial introduction of a pathogen into the host population is sufficient, then it can result in the dampening of cyclic populations. This is very similar to the effect of adequate translocation from the pathogen reservoir to the transmissible subpopulation. Values for other parameters are as given for Fig. 2, except that $\lambda = 1$.

In a similar way, stages residing in the reservoir die (ρ) or are translocated at a constant per capita rate ν to the transmissible subpopulation.

The properties of the model are straightforward. There is a single positive equilibrium only if the pathogen is sufficiently virulent (that is, $\alpha > a_1 + a_2 - b$) and if the number of stages removed from the transmissible subpopulation when infection occurs is sufficiently small. As other forms of population regulation are not included in the model, in the absence of the disease the host population grows unregulated at an exponential rate, $a_0 - b$.

As illustrated in Figs 2 and 3, the model exhibits one of two distinct types of behaviour at equilibrium: (1) stable oscillations or (2) constant population densities. The basic features of the model that determine which of these prevail are the storage and release of pathogen stages in the reservoir (governed primarily by constants λ, θ_2, $1/\rho$ and ν). Very low values of these potentials give rise to stable oscillations (Figs 2*a* and 3). As they are increased to intermediate levels, the result is constant host and pathogen populations (Figs 2*b* and 3). Finally, increasing the release potential of the reservoir (governed by the constant ν) even further produces, once again, cyclic populations (Figs 2*c* and 3). But further increases in the storage of stages (governed by the constant $1/\rho$) continues to enlarge the parameter space for constant host populations (Fig. 3). Changes in other parameters of the model may affect the boundaries of the stable and unstable equilibrium, but do not alter the central results.

There are number of real examples which support the results presented here[4-7,13-15]. The most striking of these comes from the interaction between Hepialid moths of the genus *Wiseana* and their nuclear polyhedrosis virus[4,10,18-21]. The larvae of these moths are pests of grasses in pastures in New Zealand. In long-term pasture leys, larvae that die from the disease accumulate in the upper layers of the soil to form a reservoir. Translocation of the virus from this reservoir to the larval food source (grass swards) has been attributed to the grazing of animal stock. The populations of the pest in these pastures are low and fairly constant from year to year. But management practices which disturb the pathogen reservoir (such as ploughing the pastures) and/or reduce the translocation of the pathogen from the reservoir to the grass swards (no grazing, for example) result in outbreaks of the pest, with highly variable populations from year to year. If both of these disruptive practices are halted, then the pathogen reservoir slowly builds, accompanied by the depression of the pest population. Thus, the creation of a distinct reservoir along with specific mechanisms for mobilization of the pathogen into the host population seems to mediate the differences in dynamical behaviour, which is in agreement with the model proposed here. Other real systems where pathogen reservoirs have an apparently similar role in the biological control of arthropod pests are: the Japanese beetle, *Popillia japonica*, and its bacterium, *Bacillus popilliae*[5]; the spruce sawfly, *Gilpinia hercyniae*, and its nuclear polyhedrosis virus[6]; the palm rhinoceros beetle, *Oryctes rhinoceros*, and its rhabdovirus[7]; the velvetbean caterpillar, *Anticarsia gemmatalis*, and its nuclear polyhedrosis virus[13]; the grasshopper, *Zonocerus variegatus*, and its fungus, *Entomophthora grylli*[14]; and the cabbage looper, *Trichoplusia ni*, and its nuclear polyhedrosis virus[15]. It should be stressed that, in these examples, the details of the mathematical model (for example, the amplitude and period of the cycles) are very difficult to corroborate because of the requirements of long runs of population data and accurate estimates of the parameters of the model. Rather, the crucial prediction made by the model is a strategic one: increasing the levels of release of pathogen stages from established reservoirs to the habitat of the host should lead to lower and more constant populations.

The model presented here constitutes a realistic framework for predicting the consequences of potential strategies in biological control programmes. Equally important, the model serves to clearly identify the biological factors that should be measured and manipulated, whether for experimentation or the actual practice of biological control. Measures[22] to increase the efficacy of indigenous pathogens of arthropod pests should focus on the identification and manipulation of pathogen reservoirs and the processes that move pathogens between non-transmissible and transmissible subpopulations. In particular, the conservation of potential vectors of the pathogen should be paramount. For the introduction of exotic pathogens as 'classical' biological control agents, the model suggests that the conditions for determining their likelihood of success are (1) the long lifespan of pathogen stages residing in reservoirs and (2) the propensity of these stages to be translocated to the habitat of the host for possible transmission. Thus, the screening of promising agents and systems with pathogen reservoirs in mind is a sensible practice. In the past, microbial biological control programmes[23,24] have focused on measures which yield short-term control of arthropod pests. These results indicate that long-term control is possible and may not entail much cost or effort.

Maturation and connectivity of the visual cortex in monkey is altered by prenatal removal of retinal input

In several species, the peripheral input from the eyes partly determines the pattern of interconnections between the visual areas of the two cerebral hemispheres through the fibre tract termed the corpus callosum[1-9]. In the macaque monkey, the neurons projecting through the callosum are largely restricted to area 18 throughout ontogeny, whereas area 17 is characterized by few or no callosal projections[10-12]. Here, we show that suppressing the peripheral input by prenatal removal of the eyes leads to a marked reduction in the extent of area 17, resulting in a large shift in the position of the histologically identifiable boundary between the two areas. Even so, the boundary continues to separate an area rich with callosal connections (area 18) from one poor in such projections (area 17), indicating there is no effect on the callosal connectivity of area 17. In contrast, in area 18, eye removal results in many more neurons with callosal projections than in normal animals. The results suggest that the factors that determine the parcellation of cortical areas also specify their connectivity.

Two fetal macaque monkeys (*Macaca cynomolgus*) had both eyes removed at 77±2 and 112±2 days after conception (days E77 and E112), and the fetuses were then replaced in the uterus. At about the normal time of birth the callosal connectivity of areas 17 and 18 was determined using horseradish peroxidase histochemistry.

The pattern of layers in area 17 seemed remarkably normal in both experimental animals. The border between areas 17 and 18, clearly defined in Nissl-stained sections, was as distinctive as in the neonatal control (Fig. 1 and ref. 13). The 17/18 border could also be detected in sections reacted for cytochrome oxidase activity (Fig. 1). Comparison of adjacent sections stained by the two methods reveals a double band of higher cytochrome oxidase activity in layer 4C that stops abruptly at the 17/18 border, as in the control animal[14]. Despite the weaker staining for cytochrome oxidase activity in the experimental animal its distribution within area 17 was, on the whole, similar[14].

In the monkey operated on day E77, the gyral pattern of the occipital lobe was unusual and the surface area of area 17 was considerably reduced (Fig. 2, see also ref. 13), particularly laterally where, in the intact animal, cortex subserving foveal and parafoveal vision is located. Later eye removal (on day E112) did not cause a noticeable reduction in the surface area of area 17 or a disturbance in the gyral pattern[13].

In both animals after eye removal, the disposition of callosally projecting neurons with respect to the border between areas 17

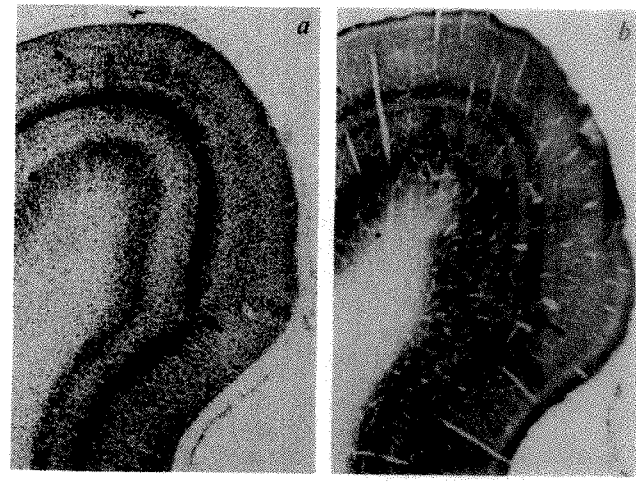

Fig. 1 Characteristics of the 17/18 border after early eye removal (E77). *a*, Section stained with cresyl violet *b*, Adjacent section reacted to show cytochrome oxidase activity. The arrows indicate the 17/18 border. Although the level of cytochrome oxidase activity is lower than in normal neonates the overall distribution in area 17 and the change in layer 4 at the 17/18 border is similar.
Methods. Timed pregnant monkeys were prepared for surgery under ketamine (i.m.) followed by Alfatesin (i.v.) anaesthesia. After intubation, anaesthesia was continued with halothane in a N_2O/O_2 mixture (70:30). Expired CO_2 and heart rate were monitored. The body temperature was maintained using a thermostatically controlled heating blanket. A midline abdominal incision was made and uterotomy performed. After exposure of the fetal head and bilateral eye removal, the fetus was replaced in the uterus and incisions closed using routine procedures. The mother was returned to her cage and medicated for the first two days with analgesic (Visceralgine, i.m.). A muscular relaxant (Duvadilan, i.m.) was given twice daily until the fetus was delivered by caesarian section 1-2 weeks before term. The infant monkey was bottle fed until the axonal tracing experiments on day E159 when removal was at E77, and E164 when eye removal was at E112 (the gestation period is 165 days). Infant monkeys were anaesthetized with ketamine (i.m.) followed by Alfatesin (i.v.). Craniotomy was performed over the occipital lobe and 15-25 μl of 30-50% horseradish peroxidase (HRP) were injected using a Hamilton syringe equipped with a glass micropipette (60-120 μm tip diameter). Closely spaced injections were made over the occipital lobe so as to massively fill area 17 and the adjacent part of area 18. After 24 hours, the infant monkey was deeply anaesthetized and perfused through the heart with a mixture of 1.25% paraformaldehyde and 1.5% glutaraldehyde. Sections (60 μm thick) were cut parasagitally and one in three sections were processed for HRP histochemistry[18]. Intermediate sections were processed for cytochrome oxidase[19] and stained for Nissl substance (cresyl violet). The border of area 17 and 18 was clearly defined in Nissl and cytochrome oxidase-reacted sections and in the hemisphere contralateral to the injection of HRP, labelled neurons were counted and allocated to either area. Counts of labelled neurons were made in area 18 from the 17/18 border to the fundus of the lunate sulcus. Individual sections were traced out and the positions of labelled cells recorded using an *x-y* plotter electronically coupled to the microscope stage.

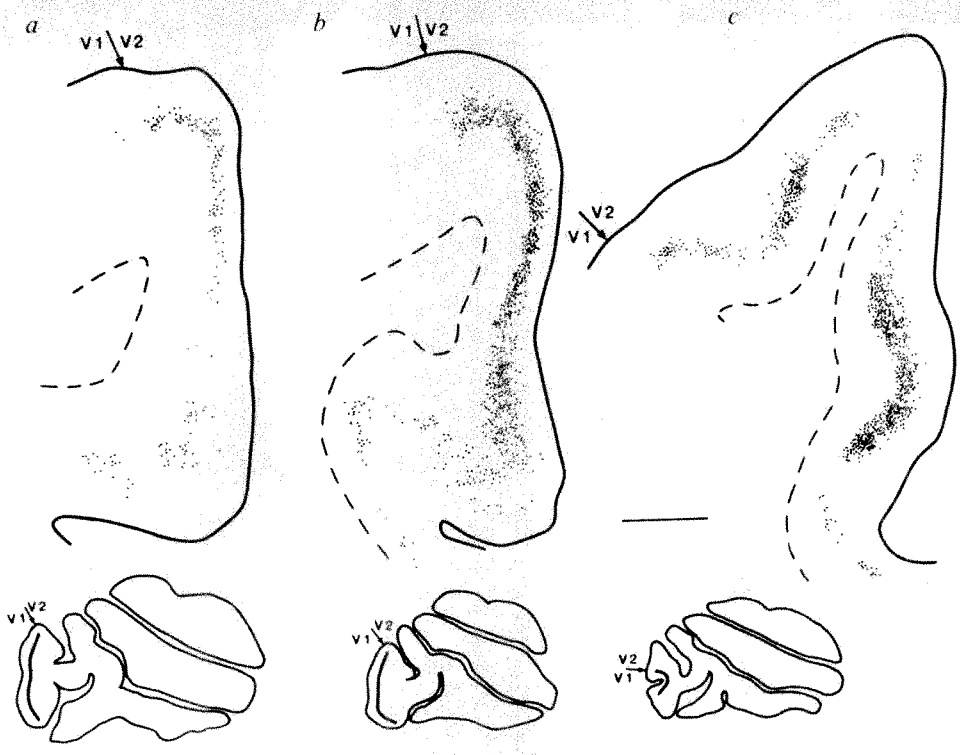

Fig. 2 Parasagittal sections of the area 17/18 border showing callosally projecting cells in the newborn monkey. *a*, Normal. *b*, Eye removal at E112. *c*, Eye removal at E77. Each dot represents a retrogradely labelled cell and arrows indicate the area 17/18 border. Inserts show low-power drawing at the level at which the high-power plots were made and where the continuous line in the operculum indicates the extent of area 17. Eye removal did not increase the numbers of callosally projecting neurons in area 17, but did increase the numbers of these cells in area 18. Whereas area 17 occupies most of the operculum of the normal animal and after eye removal at E112, after eye removal at E77, area 17 seems considerably shrunken. Scale bar, 1 mm.

and 18 was normal (Fig. 2): they were largely confined to the extrastriate cortex and stopped abruptly at the 17/18 border. In both animals, only one or two labelled neurons per section were found in area 17 where they were located, as in normal animals, within 2–3 mm of the border[11,15,16]. In contrast, in area 18, callosally projecting neurons were more densely packed and stretched further rostrally from the 17/18 border than in normal neonates (Fig. 2). Counts of callosally projecting neurons were made in the part of area 18 that extends from the 17/18 border to the fundus of the lunate sulcus, in the part of the cortex that represents the parafoveal region of the visual field. In the normal animal there were 50–140 labelled neurons per section[10,12], whereas in both experimental animals the number was 5–6 times higher (280–875) than in either normal neonates or adults (Fig. 3). Although the age at which the eyes were removed did not influence the numbers of callosally projecting neurons in area 18, it did affect their spatial distribution. The animal operated on day E112 showed a continuous distribution of callosally projecting neurons but in the animal operated on day E77 the distribution of callosally projecting neurons was discontinuous and patchy (Fig. 2).

The demonstration that eye removal alters the callosal connectivity of area 18 but not of area 17 should be considered in the light of the ontogeny of callosal connections in the monkey. Several studies have shown that area 17 is largely free of callosal connections throughout development (ref. 11; L. M. Chalupa and H. Killackey manuscript, in preparation; P. Rakic, personal communication). Eye removal, which stabilizes transient callosal connections in all other species examined[1–9], in monkey fails to reveal a transient callosal projection in area 17, emphasizing that the lack of callosal connections in area 17, unique to the monkey, is specified early in development. The normal maturation of the cortical connectivity of area 18 differs from that of area 17, as the distribution of callosally projecting neurons in area 18 changes during development[11]. Because eye removal both early and late in prenatal life leads to higher numbers of callosally projecting neurons in area 18, the elimination of the transient callosal projection, which normally occurs in the last month of gestation[11] must be regulated by epigenetic factors that depend at least partially on peripheral input.

The reduced size of area 17 after early eye removal could result from an increase in cell death. As the number of afferent fibres from the lateral geniculate nucleus in the thalamus is reduced after early eye removal (ref. 17; H. Kennedy, unpublished observation), the survival of neurons in area 17 may depend critically on the density of the input. It is also possible that the input from the thalamus contributes directly to determining cortical areas, so that the smaller number of afferents from the lateral geniculate nucleus after eye removal leads to reduction in the extent of cortex specified as area 17 and a consequent expansion of the adjacent area 18[13]. This raises the question of whether the cortex immediately adjacent to area 17 constitutes

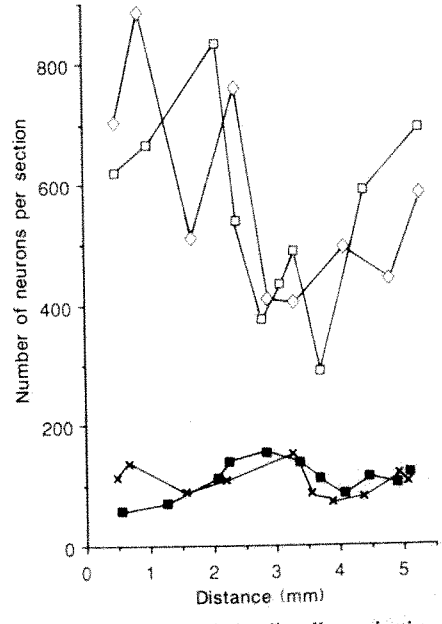

Fig. 3 Counts of HRP labelled callosally projecting neurons in area 18 of normal adult (■), neonatal control (×), after eye removal at E77 (□) and after eye removal at E112 (◇). In normal development, the numbers of callosally projecting neurons do not change after birth. Counts of callosally projecting neurons were considerably higher in the two animals whose eyes were removed. The age at which the eyes were removed had no influence on the numbers.

a hybrid area, that is, a region of cortex with characteristics of both areas 17 and 18[13]. As the absence of callosal connections from area 17 is determined early in development, it can be used to indicate whether tissue originates developmentally from area 17 or area 18. As callosally projecting neurons are found in area 18 immediately adjacent to area 17, the expanded area 18 seems to be a cortical region that was unspecified when the eyes were removed and, because of the subsequent lack of peripheral input, failed to mature into area 17.

These results indicate that retinal input has several, somewhat independent effects on cortical development. Early in development the factors that help to specify the limits of cortical visual areas also regulate the overall presence or absence of callosal connectivity. Once the boundaries of areas are established, the influence of peripheral input is limited to regulating the density of callosal projection neurons in extrastriate visual cortex.

Effect of recombinant soluble CD4 in rhesus monkeys infected with simian immunodeficiency virus of macaques

Mamoru Watanabe, Keith A. Reimann, Peter A. DeLong, Theresa Liu*, Richard A. Fisher*, & Norman L. Letvin†

Harvard Medical School, New England Regional Primate Research Center, Southborough, Massachusetts 01772, USA
* Biogen Research Corporation, 14 Cambridge Center, Cambridge, Massachusetts 02142, USA

The CD4 molecule is a high-affinity cell-surface receptor for the human immunodeficiency virus (HIV-1)[1] and a soluble truncated form of CD4 produced by recombinant DNA technology is a potent inhibitor of HIV-1 replication and HIV-1-induced cell fusion *in vitro*[2–6]. Rhesus monkeys infected with the simian immunodeficiency virus of macaques (SIV_{MAC}), a virus closely related to HIV-1, develop an AIDS-like syndrome, and so provide an important model for the evaluation of potential AIDS therapies[7]. We have assessed the therapeutic effect of recombinant soluble CD4 in SIV_{MAC}-infected rhesus monkeys. Virus was readily isolated from peripheral blood lymphocytes and bone marrow cells of these animals before starting treatment with soluble CD4, but became difficult to isolate soon after treatment had begun. Moreover the diminished growth of both granulocyte-macrophage and erythrocyte progenitor colonies from the bone marrow of these monkeys rose to normal levels during treatment. These findings indicate that soluble CD4 could prove valuable in the treatment of AIDS.

† To whom correspondence should be addressed.

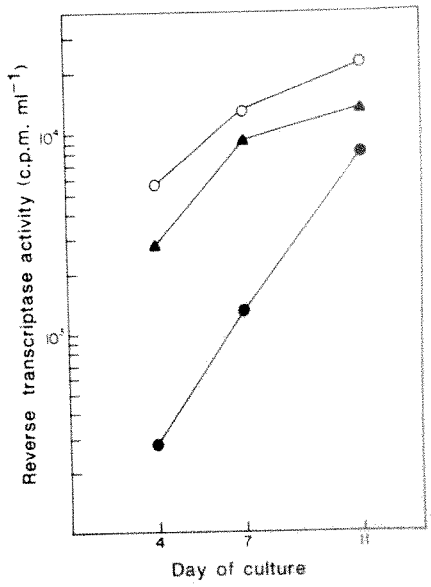

Fig. 1 Inhibition by rsCD4 of SIV_{MAC} infection of normal rhesus monkey PBLs *in vitro*. SIV_{MAC}-containing culture supernatant was incubated for 1 h at 37 °C with culture medium alone or with two concentrations of rsCD4 and then added to 2.5×10^6 cell aliquots of concanavalin A activated normal rhesus monkey PBLs in 1 ml, resulting in final concentrations of no rsCD4 (○), 12.5 μg ml^{-1} rsCD4 (▲), and 125 μg ml^{-1} rsCD4 (●). After a 2-h incubation at 37 °C, these cells were brought up to 5 ml in IL-2-supplemented medium. Following an overnight incubation, the cell populations were washed, resuspended in IL-2-supplemented medium at 5×10^5 cells per ml and maintained at 37 °C in a humidified 5% CO_2 atmosphere. Culture medium was collected every 3–4 days and assayed for reverse transcriptase activity[14].

Our growing understanding of HIV-1 and its interaction with the cells it infects is leading to rational strategies for AIDS therapy. The CD4 molecule acts as a high-affinity receptor for the outer viral envelope glycoprotein (gp120) of HIV-1[1]. Monoclonal anti-CD4 antibodies block the ability of HIV-1 to infect target cells *in vitro*[8,9], and the transfer and expression of the CD4 gene to previously $CD4^-$ human cells confers susceptibility to HIV-1 infection on those cells[10]. It has recently been shown that a recombinant soluble form of the CD4 molecule (rsCD4) is a potent inhibitor of both HIV-1 replication and virus-induced cell fusion *in vitro*[2–6]. These findings led to the proposal that rsCD4 may be useful in AIDS therapy.

Lentiviruses related in their nucleotide sequences to the human AIDS viruses HIV-1 and HIV-2 have recently been isolated from African and Asian non-human primates[11]. Some of these isolates, when inoculated into rhesus monkeys, induce a disease with striking similarities to human AIDS[7,12,13]. The SIV_{MAC}-induced disease in the rhesus monkey has already proved to be an important model for studying the pathogenesis of AIDS and for assessing strategies for vaccination and therapeutic interventions in this disease[14,15]. The human and macaque CD4 molecules are strikingly similar both in their monoclonal anti-CD4 epitope mapping and in their amino-acid sequences that define the minimal region for binding the outer envelope glycoprotein of the AIDS virus (R.A.F. *et al.*, unpublished data). In agreement with these observations, we find that a recombinant soluble human CD4, a 375-amino acid protein comprising the entire extracellular portion of the molecule[2], blocks rhesus monkey peripheral blood lymphocyte (PBL) infection by SIV_{MAC} *in vitro* (Fig. 1). Although human rsCD4 may

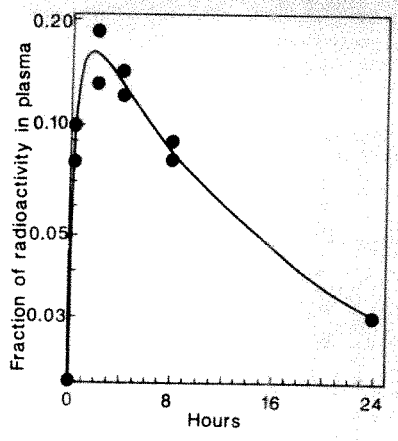

Fig. 2 Plasma clearance of total radioactivity from 2 rhesus monkeys following intramuscular administration of ^{125}I-labelled rsCD4. Radiolabelled rsCD4 (1.1×10^7 c.p.m.) was administered with 2 mg unlabelled rsCD4, i.m., into each of 2 normal 6.9 kg rhesus monkeys. Samples of plasma (1 ml) were regularly analysed for radioactivity. The fraction of the total initial radioactivity in the plasma was calculated assuming a plasma volume of 40 ml kg^{-1}.

be less efficient in blocking SIV_{MAC} infection of rhesus monkey PBLs than HIV-1 infection of human PBLs, the SIV/rhesus monkey model provides a reasonable system in which to assess the therapeutic potential of rsCD4 in AIDS.

Pharmacokinetic studies were performed to establish an appropriate route and frequency of administration of rsCD4 to the rhesus monkey. Animals weighed 5–7 kg. Two normal rhesus monkeys were given a single 2 mg intramuscular (i.m.) inoculation of rsCD4 with a trace quantity of ^{125}I-labelled rsCD4 admixed. As shown in Fig. 2, >10% of the calculated maximum possible fraction of radioactivity was found in plasma 15 min after a single dosage and persisted for 8 hours. Peak plasma levels of >1,400 ng ml^{-1} of rsCD4 were measurable in an enzyme-linked immunosorbent assay two hours after its administration. This method of delivery yielded an estimated rsCD4 serum half life of about 6 hours. Two uninfected rhesus monkeys were then given a 50-day course of rsCD4 treatment, each receiving 2 mg, i.m., daily, and did not experience any significant adverse reaction to the rsCD4. The distribution of lymphocyte subsets in their peripheral blood ($CD2^+$, $CD4^+$, $CD8^+$, IL-2-receptor$^+$, $B1^+$) and the function of those cells (proliferation following stimulation with xenogeneic cells and pokeweed mitogen) did not change during the course of treatment. Serum chemistry studies to assess liver and renal function on days 8, 15 and 44 of treatment and on days 8 and 18 after treatment were unchanged when compared with baseline values. The animals did experience a transient drop in the number of bone marrow granulocyte-macrophage progenitor (CFU-GM) colonies with an associated transient neutropenia, but this transient bone marrow suppression never became clinically significant.

Four SIV_{MAC}-infected rhesus monkeys were then treated with rsCD4 in the same way. Three of these virus-infected monkeys had nearly normal immune parameters at the start of treatment; the fourth had a circulating absolute $CD4^+$ lymphocyte count of less than 100 per mm^3 (normal rhesus monkeys have >1,000 $CD4^+$ PBLs per mm^3). None of the SIV_{MAC}-infected monkeys showed changes during treatment in the distribution of lymphocyte subsets in their peripheral blood, in PBL function or in serum chemistry assessment of liver and renal function. The SIV_{MAC}-infected animal (Mm167-84) that showed evidence of severe immunological impairment at the start of the study died on the third day after the end of treatment. There was evidence of a severe Coombs positive haemolytic anaemia. In the last 10 days before death, the animal's haemoglobin dropped from 7.7 to 3.7 g dl^{-1}. Lesions seen at necropsy included a large amount of clotted blood in the small intestine, severe myocardial fibrosis, and histiocytic infiltration of the splenic lymphoid follicles. These last two findings are not uncommon in rhesus monkeys chronically infected with SIV_{MAC}. The presence of blood in the proximal small bowel indicated that the animal could have died from an acute gastrointestinal haemorrhage, which was possibly secondary to stress induced by the acute haemolytic process. As significant haemolytic anaemias have been reported in AIDS[16], it is impossible to determine whether this death was a natural consequence of the SIV_{MAC} infection or was drug-induced.

The results of the virus-isolation studies in these four monkeys were striking (Fig. 3). Co-cultivation of PBLs from animals Mm156-85, Mm159-86 and Mm202-84 with H9 yielded SIV_{MAC} before treatment and on every isolation attempt up to about the end of week 2 of treatment. These virus isolation attempts thereafter were negative until one month after completion of treatment at the earliest. SIV_{MAC} replication in bone marrow cultures, a reflection of virus replication in macrophages rather than in T lymphocytes (data not shown) showed parallel

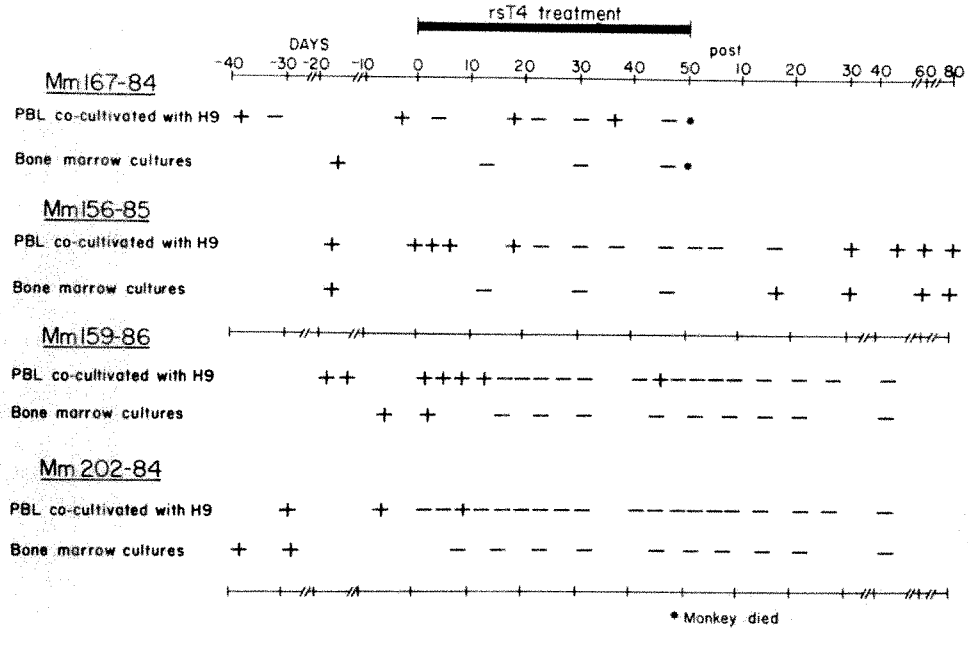

Fig. 3 SIV_{MAC} could not be isolated from PBLs and bone marrow of the virus-infected monkeys during treatment with rsCD4. PBLs of SIV_{MAC}-infected animals were isolated by Ficoll-diatrizoate density gradient ($\rho = 1.077$) centrifugation, activated with concanavalin A and co-cultured with the human T-cell line H9. Bone-marrow samples were obtained by posterior iliac crest aspiration from ketamine anesthetized monkeys and heparinized. Cells were isolated by density gradient centrifugation, washed and placed in culture in Iscove's modified Dulbecco's MEM supplemented with 12.5% FBS and 12.5% horse serum in 2 or 4 chamber Lab-Tek tissue culture slides (Miles Scientific) at a cell concentration of 1×10^6 per ml. After 7 days of culture, non-adherent cells were removed. In both culture systems, medium was changed regularly and supernatants were assayed for reverse transcriptase activity as previously described[14]. Supernatants with reverse transcriptase activity at least 5 times above background were scored as positive for infection.

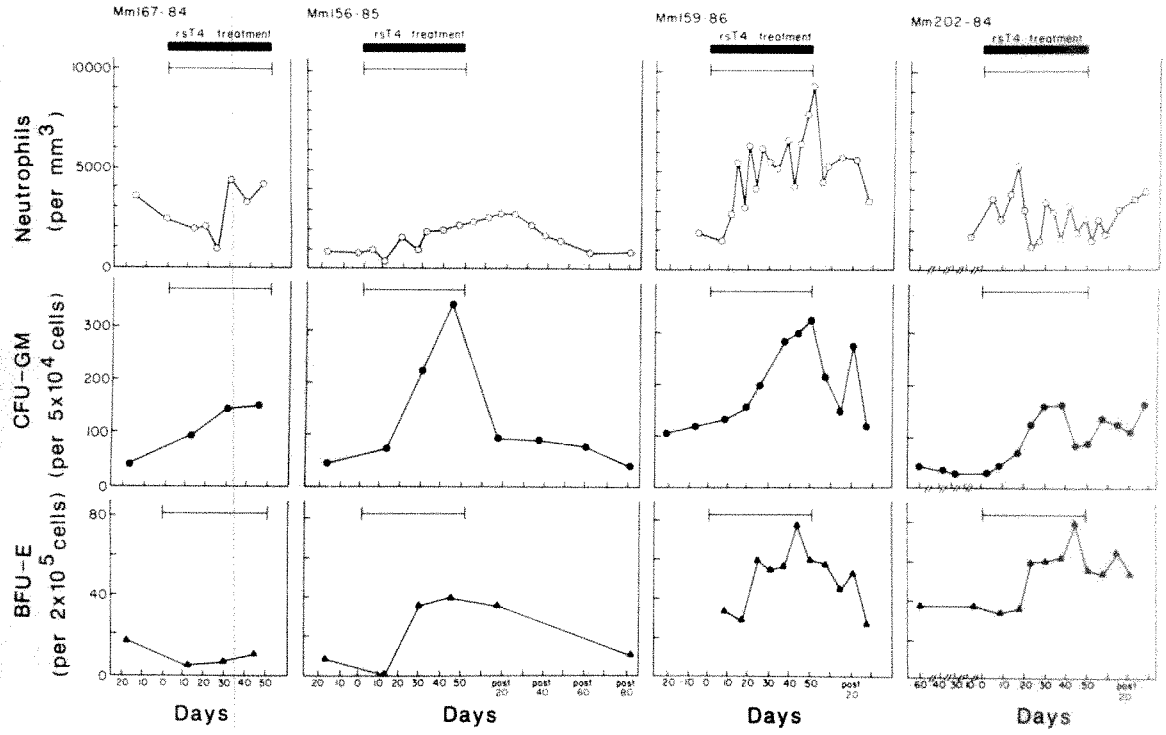

Fig. 4 SIV_{MAC}-infected rhesus monkeys demonstrate an increase in bone marrow granulocyte-macrophage and erythrocyte progenitor cell growth following rsCD4 treatment. A two-layer culture was established for the quantitation of CFU-GM colonies from bone marrow cells isolated as described in Fig. 3. The underlayer of 0.5% Noble agar contained 60 ng ml^{-1} recombinant human granulocyte-macrophage colony stimulating factor (kindly provided by Genetics Institute, MA). The overlayer contained 10^5 bone marrow cells in Iscove's modified DMEM supplemented with 12.5% FBS and 12.5% horse serum in 0.3% Noble agar. It was layered on to the underlayer in 35 × 10 mm tissue-culture dishes and the cultures were maintained at 37 °C in a 5% CO_2-humidified atmosphere. BFU-E colonies were assessed in cultures of bone marrow cells maintained in 0.9% (w/v) methylcellulose in Iscove's modified DMEM supplemented with 30% FBS, 0.9% deionized bovine serum albumin and 5×10^{-5} M 2-mercaptoethanol, containing 60 ng ml^{-1} granulocyte-macrophage colony stimulating factor, 1 unit ml^{-1} sheep erythropoietin (step III, Connaught Lab., Ontario) and 5% phytohaemagglutinin-stimulated rhesus monkey lymphocyte conditioned medium. CFU-GM and BFU-E colonies of >50 cells were then counted under an inverted microscope 12–14 days after establishing the cultures. Total neutrophil counts in the peripheral blood were determined from complete blood counts and differentials from EDTA-anticoagulated blood samples.

changes. Virus was readily isolated from bone marrow before treating these 3 monkeys, but attempts to isolate virus during treatment were negative. Virus isolations from bone marrow reverted to positive on day 18 after completion of treatment in Mm156-85, but remained negative until 43 days after treatment in Mm159-86 and Mm202-84. Virus was isolated only episodically from PBLs of the SIV_{MAC}-infected rsCD4-treated animal Mm167-84 following co-cultivation with H9 cells both before and during treatment (Mm167-84 was the animal that was immunologically compromised at the outset of the study and died 3 days after completion of treatment). But although isolation of virus from the bone marrow of Mm167-84 was positive before treatment, 3 attempts to isolate virus from the bone marrow during treatment were unsuccessful.

These negative virus isolations alone were not unequivocal evidence for a therapeutic effect of rsCD4; the rsCD4 could simply have interfered with the *in vitro* isolation of SIV_{MAC} without affecting virus replication or the sequelae of these infections in the monkeys. But the fact that virus isolations remained negative in three animals for longer than a month after treatment argues against this possibility. Moreover, functional abnormalities reflecting SIV_{MAC}-induced disease also improved in these animals. The *in vitro* growth of both CFU-GM and erythrocyte progenitor (BFU-E) colonies from the bone marrow of these monkeys was depressed at the start of rsCD4 treatment. This is a common finding in SIV_{MAC}-infected monkeys (data not shown) and in HIV-1-infected humans[17]. (CFU-GM colony counts in a series of studies of 10 normal animals were 222 ± 16 per 5×10^4 cultured bone marrow cells; BFU-E counts were 76 ± 4 per 2×10^5 cultured bone marrow cells.) The number of colony-forming cells from the bone marrow of these animals increased during rsCD4 treatment (Fig. 4). A bone marrow cell CFU-GM colony count of 48 per 5×10^4 cells before treatment of Mm167-84 rose during treatment to 146 per 5×10^4 cells with no significant change in the number of BFU-E colonies. The CFU-GM colony count derived from bone marrow of Mm156-85 rose from 44 per 5×10^4 cells before the start of therapy to 350 per 5×10^4 cells, with a coincident rise in BFU-E colonies from 8 to 40 per 2×10^5 cells. Bone marrow from Mm159-86 showed a rise in CFU-GM colonies from 106 to 329 per 5×10^4 cells and in BFU-E colonies from 34 to 78 per 2×10^5 cells. Bone marrow from Mm202-84 gave an increase in CFU-GM colonies from 46 to 163 per 5×10^4 cells and in BFU-E colonies from 38 to 80 per 2×10^5 cultured cells. A decline in bone marrow CFU-GM and BFU-E colony counts to baseline values occurred in the three surviving animals after stopping treatment. A transient neutropenia occurred in two of the four monkeys during the first two weeks of treatment. But there was an eventual rise in total peripheral blood neutrophil count in all four animals that accompanied the increased colony-forming cell count from the bone marrow.

The rsCD4 treatment of the two normal rhesus monkeys unexpectedly had an anti-viral effect. More than 90% of bone marrow cultures established from uninfected monkeys can be reproducibly infected with exogenously introduced SIV_{MAC} (data not shown). But although bone marrow from both the rsCD4-treated normal animals was susceptible *in vitro* to infection with SIV_{MAC} introduced before and 4 weeks after treatment, 3 attempts to infect bone marrow cell cultures from the animals during the 50-day treatment period and a single attempt 18 days afterwards gave negative cultures.

Our inability to isolate virus from PBLs of the SIV_{MAC}-

infected animals by H9 co-cultivation during rsCD4 treatment did not mean that these animals were cleared of virus. If $CD8^+$ lymphocyte-depleted rhesus monkey PBLs are co-cultivated with human PBLs in IL-2-supplemented medium, low levels of virus infection can be detected[18]. Using this method we were able to isolate virus from these animals during treatment. Nevertheless virus was more difficult to isolate during treatment than before and after treatment, and this probably reflects a quantitative decrease in replication of SIV_{MAC} in these animals. The coincident improvement in bone marrow function during this period of treatment is a functional benefit probably related to the decreased virus load. This increase in bone marrow colony-forming cells was not seen in the treated normal animals. The unexpected protection of bone marrow cultures from treated normal animals against SIV_{MAC} infection suggests another therapeutic benefit of rsCD4 treatment.

It has been suggested that rsCD4 could act by absorbing soluble gp120 and thus interfering with cytolytic T lymphocyte killing of HIV-1 infected targets, or by inhibiting cell fusion, or by direct blocking of virus-target cell binding[19]. It could also act indirectly to provide a therapeutic benefit to HIV-1-infected individuals. Although we do not know the precise mechanism by which it works, the beneficial effect of the rsCD4 treatment in SIV_{MAC} -infected rhesus monkeys suggests that it could be of value in treatment of humans infected with HIV-1.

We thank N. King for pathology; C. Lord, K. Solomon, S. Turner, M. Stone and B. Burrus for technical assistance; M. Evans for help with animal treatments; J. Maragarore, W. Meier and the Biogen Process Development Group for preparation of the rsCD4; V. Johnson for assistance with the Coombs assay; R. Schooley and V. Sato for discussion and D. Brosseau for preparing the manuscript. This work was supported by Biogen, Inc, and the NIH.

Induction of endogenous IFN-α and IFN-β genes by a regulatory transcription factor, IRF-1

Takashi Fujita, Yoko Kimura, Masaaki Miyamoto, Edward L. Barsoumian & Tadatsugu Taniguchi

Institute for Molecular and Cellular Biology Osaka University, Suita-shi, Osaka 565, Japan

Interferons (IFNs) have an important role in cell growth and differentiation. The most well-known function of IFNs is their antiviral activity; viral infections result in induction of the transcription of the IFN-α and IFN-β genes[1-3]. Recently we isolated the gene encoding a transcription factor, IRF-1, that may play a part in the induction of IFN genes[4,5]. Interestingly, the IRF-1 gene itself is virus-inducible, suggesting the importance of *de novo* production of IRF-1 in IFN gene induction[5]. Here we show that high-level expression of the cloned mouse IRF-1 gene in monkey COS cells results in the induction of endogeneous IFN-α and IFN-β genes without viral stimulation. Furthermore, we demonstrate the induction of these genes by an IRF-1/yeast GAL4 chimaeric transcription factor. This may be the first demonstration of the specific induction of silent chromosomal genes by transfection of a single transcription factor gene in mammalian cells.

Fig. 1 Expression of murine IRF-1 and its derivatives in COS cells. *a*, Structure of expression vectors. Numbers in parentheses indicate the amino-acid residues of each factor. In all constructs the genes were inserted into the expression vector CDM8, which contains the cytomegalovirus (CMV) promoter/enhancer and the SV40 *ori* sequences[13]. They were (1) pCMIRS, which contains the entire mouse IRF-1 coding sequence downstream of the CMV promoter/enhancer sequence in the sense orientation; (2) pCMIRA, which is the same as pCMIRS except that the IRF-1 gene is introduced in the antisense orientation; (3) pCMIRD, in which a translational terminator sequence has been introduced within the cDNA sequence of pCMIRS, resulting in a gene product that lacks the carboxyl-terminal portion of the IRF-1 (that is, downstream from amino acid 189); (4) pCMIRG, which encodes a chimaeric factor consisting of the amino-terminal portion of IRF-1 and the yeast GAL4 transcriptional activation domain[14]. *b*, Detection of DNA-binding activity in COS cell transfectants. DNA transfection was performed by a method modified from Seed and Aruffo[15]. COS cells in a 10-cm dish (5×10^6 cells per dish) were transfected in 5 ml Iscove's modified Eagle's medium containing 10% NuSerum, 500 $\mu g\ ml^{-1}$ DEAE dextran, 100 μM chloroquin diphosphate and 5 $\mu g\ ml^{-1}$ plasmid DNA. Transfection efficiency of this protocol is ~30%, as estimated by the Tac antigen (IL-2 receptor)-positive COS cell population after transfection of pSVIL2R-3 (ref. 16). Whole cell extracts of transfected COS cells with pCMIRA (lanes 2 and 3), pCMIRS (lanes 4 and 5), pCMIRD (lanes 6 and 7) and pCMIRG (lanes 8 and 9) were prepared 48 h after transfection[4]. Each extract was subjected to gel shift analysis using ^{32}P-labelled C13 oligomer (sequence AAGTGA repeated 3 times in tandem) as probe[6]. The binding mixture (10 μl) contains 20 mM HEPES, *p*H 7.6, 0.5 mM dithiothreitol, 0.1 mM EGTA, 1 mM $MgCl_2$, 4% Ficoll, herring sperm DNA (1 μg), poly(dI-dC)·poly(dI-dC) (2 μg), ^{32}P-probe (5 fmole) and 2 μg protein of whole-cell extract. In lanes 3, 5, 7 and 9, a molar excess of unlabelled C1 oligomer (AAGTGA repeated 4 times in tandem)[6] (5 pmole) is also included. Lane 1: no extract. A low-level of the monkey IRF-1-like activity can be seen in lane 2. The shifted bands migrating faster in lanes 4 and 8 might be breakdown products of IRF-1 which still retain the DNA-binding property of native IRF-1. The intensity of the shifted bands was about 8 (pCMIRS), 110 (pCMIRD) and 32 (pCMIRG) relative to the control (pCMIRA). Following viral induction, a twofold increase is observed in untransfected controls (data not shown).

In order to study the function of IRF-1 in IFN gene expression, we constructed a series of expression vectors for the mouse IRF-1 gene[5] (Fig. 1*a*). The expression vectors were each transfected into monkey COS cells and the gene products were analysed by gel retardation using cell extracts and a ^{32}P-labelled C13 oligomer probe[6]. As shown in Fig. 1*b*, a significant increase in DNA binding activity was observed in the transfectants pCMIRS, pCMIRD and pCMIRG, demonstrating that the expected products are in fact produced in large amounts (see legend).

We next tested whether the increased IRF-1 expression results in the induction of otherwise silent IFN genes. As shown in

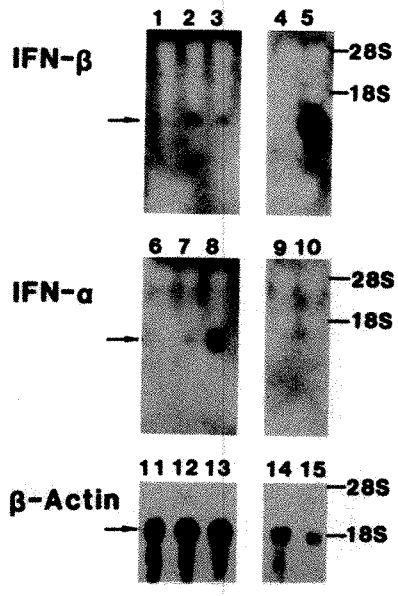

Fig. 2 Detection of IFN-β and IFN-αI specific messenger in COS cell transfectants. Twenty μg poly(A)$^+$ RNA from COS cells transfected with pCMIRA (lanes 1, 6 and 11), pCMIRS (lanes 2, 7 and 12) and pCMIRG (lanes 3, 8 and 13) and 10 μg total RNA from mock-infected COS cells (lanes 4, 9 and 14) and NDV-infected (10 h) COS cells (lanes 5, 10 and 15) were subjected to northern blotting analysis. It has been shown that cross-hybridization analysis of monkey genomic DNA with human IFN-α and IFN-β probes results in very similar patterns under stringent hybridization conditions[17]. Hybridization was with a ^{32}P-labelled human IFN-β probe (1.6-kilobase (kb) *Bam*HI-*Eco*RI fragment of pSE-66 (ref. 18), 8×10^8 c.p.m. μg^{-1}, lanes 1–5), human IFN-αI probe (0.7 kb HgiAI fragment of Hif-2h cDNA[19], 9.2×10^8 c.p.m. μg^{-1}, lanes 6–10) and human β-actin probe (2.0 kb *Bam*HI-*Pvu*II fragment of λHa-204 (ref. 5), 8×10^8 c.p.m. μg^{-1}, lanes 11–20). The filters were exposed at −80 °C for 2 days (IFN-α and IFN-β) or 4 h (actin). Densitometric measurement revealed the relative intensities of the bands in lanes 2, 3, 5, 7 and 8 as 1, 1, 259, 1 and 8.7, respectively. The apparent increase in IFN-α mRNA in lane 8 possibly represents induction of multiple IFN-α genes, the product of which might not have the same specific activity[2]. 28S and 18S ribosomal RNA size markers are shown to the right.

Table 1 IFN production in COS cells

COS cell supernatant	Interferon activity (U/5×10^6 cells) Experiment 1	2
Virus-induced cells		
Mock-induced (control)	<1	ND
NDV-induced*	5,120	ND
NDV-induced +anti-Namalwa-IFN†	5,120	ND
NDV-induced +anti-IFN-β‡	<1	ND
Antiviral activity in DNA-transfected cells		
pCMIRA	<1	<1
pCMIRS	160	160
pCMIRD	<1	<1
pCMIRG	320	230
pCMIRG+anti-Namalwa IFN	ND	80
pCMIRG+anti-IFN-αII§	ND	60
pCMIRG+anti-IFN-β	ND	110
pCMIRG+anti-Namalwa, αII and β	ND	<1
IFN-β specific ELISA‖		
pCMIRD	ND	<1
pCMIRG	ND	14

Values are standardized against reference human IFN-β. ND, not determined.

* Virus inactivated at *p*H 2.

† Anti-Namalwa IFN-α serum (polyclonal) (from Dr S. Yonehara, Tokyo Metropolitan Institute of Medical Science), final concentration 1%. The purified Namalwa-derived IFN used for the antibody preparation consists mainly of IFN-αI, but the presence of IFN-αII and IFN-β are not strictly ruled out (ref. 12; S. Yonehara, personal communication). Therefore, the IFN-αI level measured by the neutralization experiment could be an overestimation.

‡ Anti-human IFN-β serum (polyclonal) (from Dr T. Sudo, Biomaterial Institute, Tokyo), final concentration 2.5%.

§ Anti-recombinant human IFN-αII serum[7] (polyclonal) (from Dr G. Adolf, Ernst Boehringer Institut für Arzneimittelforschung, Vienna), final concentration 2.5%.

‖ Enzyme-linked immunosorbent assay (Toray, Tokyo). The value is likely to be an underestimation as the antibodies (the enzyme conjugate consists of a monoclonal antibody) are against human and not monkey IFN-β.

Table 1, antiviral activity was detectable in culture supernatants of the COS cells transfected with pCMIRS and pCMIRG but not with pCMIRA and pCMIRD. The detected IFN activity was attributable to IFN-αI, IFN-αII (also referred to as IFN-ω; ref. 7) and IFN-β. The IFN-β production was also confirmed by enzyme-linked immunosorbent assay. A combination of antibodies specific for human IFN-αI, αII and β completely neutralized the antiviral activity, implying that type II IFN (IFN-γ) was not generated using the transfectants. In contrast, COS cells infected with Newcastle disease virus (NDV) produced primarily IFN-β (Table 1). Induction of IFN mRNA was analysed by northern blotting. Both IFN-α and IFN-β messenger RNAs were detected specifically in the pCMIRS- and pCMIRG-, but not in pCMIRA- and pCMIRD-transfected COS cells. Although IRF-1 displays a lower affinity for IFN-αI compared with IFN-β (ref. 5), comparable levels of mRNA were induced. The overall IFN-α mRNA may be a reflection of the multiple subtypes induced[2]. The levels of IFN-β mRNA were much lower when compared with NDV-induced COS cells, but the mRNA size was the same in all samples, suggesting that mRNA initiation had occurred at the genuine CAP site of each gene. Similar results were obtained by expressing a complementary DNA encoding the human IRF-1 (data not shown). From the data, it seems that the amino-terminal region of IRF-1 is responsible for recognition of the regulatory DNA sequences, whereas the carboxyl-terminal region participates in activating transcription. IFN-α mRNA seems to be preferentially induced by the chimaeric factor (Fig. 2).

Two interesting issues arise from these observations: (1) Why is the IFN-β expression level much lower in the transfected cells compared with the NDV-induced cells? (2) Why are IFN-α genes induced by transfecting the IRF-1 cDNA but not by NDV in COS cells? In addressing the first question, it is possible that the IFN-β gene is subject to control mechanisms(s) that can be relieved upon viral induction[4,8–10]. In the IRF-1 gene-transfected cells, IRF-1 produced in large amounts might overcome such a control mechanism, resulting in activation of transcription, albeit at a low level. Alternatively, an additional signal(s) that can be delivered following viral infection may be needed[4,6]. In fact, NDV induction of pCMIRS-transfected COS cells resulted in about a 3- and 4-fold increase in induced IFN-β and IFN-α mRNA respectively (data not shown). These possibilities are not mutually exclusive. As for the second question, the molecular events causing this interesting difference are unclear at present. It is most likely that IRF-1 promotes transcription of IFN-α genes by interacting with their regulatory elements, because many, if not all, of the genes contain the elements recognized by IRF-1[4,5,10]. It is possible that the factor binds to those elements by displacing proteins (either specific factors or non-specific proteins such as histones) bound to chromosomal IFN-α genes. In cells that can naturally produce IFN-α, for example monocytes or B cells[1,2,11], the chromosomal structures might be

different from IFN-β. The results presented in this study provide strong evidence that the IRF-1 regulates the expression of type I IFN genes.

We thank Dr Jan Vilček for critically reviewing the manuscript, and Drs J. Ma and M. Ptashne for RB968 and for valuable comments. The work is supported in part by a grant-in-aid for Special Project Research, Cancer Bioscience from the Ministry of Education, Science and Culture of Japan, and by the Nissan Science Foundation.

Phosphorylcholine acts as a Ca^{2+}-dependent receptor molecule for lymphocyte perforin

Jürg Tschopp, Sylvie Schäfer, Danièle Masson, Manuel C. Peitsch & Christoph Heusser*

Institute of Biochemistry, University of Lausanne, CH-1066 Epalinges, Switzerland
* Ciba-Geigy AG, CH-4002 Basle, Switzerland

Large granular lymphocytes and cytolytic T-lymphocytes (CTL) contain numerous cytoplasmic granules thought to be responsible, at least in part, for the cytolytic activity of these effector cells. Isolated granules are lytic for a variety of target cells and the granule proteins are specifically released upon target-cell interaction[1-4]. Major proteins in mouse CTL granules are a family of seven serine proteases designated granzymes A to G[5], and a pore-forming protein called perforin (cytolysin)[1-4,6]. Purified perforin is cytolytic in the presence of Ca^{2+} and shows ultrastructural, immunological and amino-acid sequence similarities to complement component C9[6-8]. Despite these similarities, perforin and C9 are clearly distinct in their mode of target-cell recognition. Whereas C9 insertion is absolutely dependent on a receptor moiety assembled from the complement proteins C5b, C6, C7, and C8[9] on the target-cell membrane, no requirement for a receptor molecule has been reported for perforin. Here, we demonstrate that phosphorylcholine acts as a specific, Ca^{2+}-dependent receptor molecule for perforin.

Although complement component C9, in the absence of the C5b-8 receptor complex, inserts into and lyses small unilamellar vesicles[9], large multilamellar vesicles or membranes of erythrocytes are refractory to this C9 attack[10]. C9 is only able to intercalate non-specifically into the lipid bilayer without a receptor molecule if the density of lipid headgroups is low, as in the case of highly curved small vesicles. Similarly, perforin lyses small vesicles or other types of unilamellar vesicles without any apparent lipid specificity or need for a proteinaceous receptor molecule[2,11,12]. To exclude the possibility of non-specific insertion into this class of vesicles however, large multilamellar vesicles were tested for their inhibitory activity of perforin-mediated cytolysis. It has been shown that vesicles or lipoproteins compete with the red blood cell membrane for the binding of perforin and, hence, reduce the activity of perforin in a haemolytic assay[13-15]. Figure 1*a* shows that only vesicles containing lipids with phosphorylcholine headgroups such as sphingomyelin and phosphatidylcholine were inhibitory. This is consistent with the observation that perforin-mediated haemolysis is inhibited by 1 mM choline phosphate, whereas the presence of 50 mM ethanolamine phosphate, has no effect[15]. Moreover, phosphorylcholine-modified bovine serum albumin (BSA) was a potent inhibitor at 3 μg ml^{-1} (corresponding to approximately 1.3 μM phosphorylcholine molecules), whereas no competition of perforin-induced haemolysis was observed by non-modified BSA (Fig. 1*b*).

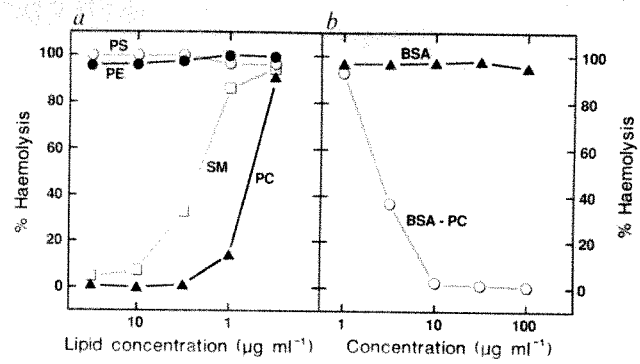

Fig. 1 Inhibition of perforin-mediated haemolysis by lipid vesicles. *a*, Inhibition of haemolysis by vesicles composed of phosphatidylcholine (PC, ▲), phosphatidylserine (PS, ○), phosphatidylethanolamine (PE, ●), sphingomyelin (SM, □), plus cholesterol in a 1:1 molar ratio. *b*, Inhibition of haemolysis by phosphorylcholine-BSA conjugates (BSA-PC, ○) or as control, by BSA (▲). Both phosphorylcholine and *p*-nitrophenylphosphorylcholine inhibited perforin's lytic activity at 1 mM (data not shown) indicating that the measured inhibition was indeed due to the phosphorylcholine moiety and not a result of the linker molecule used for its cross-linking to BSA.

Methods. Multilamellar liposomes of phospholipids and cholesterol were prepared by mixing 0.5 μmol of the phospholipid (Sigma) with 0.5 μmol of cholesterol in chloroform. The mixture was evaporated under reduced pressure to form a lipid film on the wall of a conical-bottomed flask. The dried lipid film was hydrated by vortexing at 50 °C in 0.1 ml of Tris-buffered saline (TBS, 10 mM Tris-HCl, *p*H 7.4, 150 mM NaCl). The liposome preparation was washed twice in the same buffer before use. Phosphorylcholine-conjugated BSA was prepared by incubating BSA (Fluka) with a 60-fold molar excess of *p*-diazonium phenylphosphorylcholine, synthesized as described[24], for 2 h at 20 °C in 0.035 M sodium borate buffer *p*H 9.2, containing 0.08 M NaCl. The excess reagent was removed by dialysis. Approximately 29 haptenic groups were bound per BSA molecule. The haemolytic activity of perforin was assessed as described[7]. Briefly, perforin (100 μl of a concentration that had been adjusted to lyse 80% of the sheep red blood cells) was mixed with 10 μl of liposomes or BSA and immediately added to sheep erythrocytes (1.5×10^7 cells ml^{-1}) in 300 μl veronal buffered saline (GVB, 10 mM veronal buffer *p*H 7.4, 142 mM NaCl, 0.1% gelatin, and 0.15 mM Mg^{2+}). The mixture was incubated for 15 min at 37 °C, the erythrocytes spun down and the degree of haemolysis measured by determining the haemoglobin release at 405 nm.

Direct evidence for perforin binding to phosphorylcholine was obtained by applying perforin or a CTL-granule extract (containing perforin and the granzyme lymphocyte proteases as major components) onto a nitrophenylphosphorylcholine-Sepharose column. At normal ionic strength and in the presence of 5 mM Ca^{2+}, perforin bound to the column (Fig. 2). At Ca^{2+} concentrations below 0.1 mM, perforin was not retained (Table 1). Once perforin had bound to the column, the removal of Ca^{2+} by washing the column with 'Ca^{2+}-free' buffer did not release perforin; it only eluted after the addition of 5 mM EDTA. Ca^{2+} could not be replaced by Mg^{2+} (Table 1). Binding of perforin

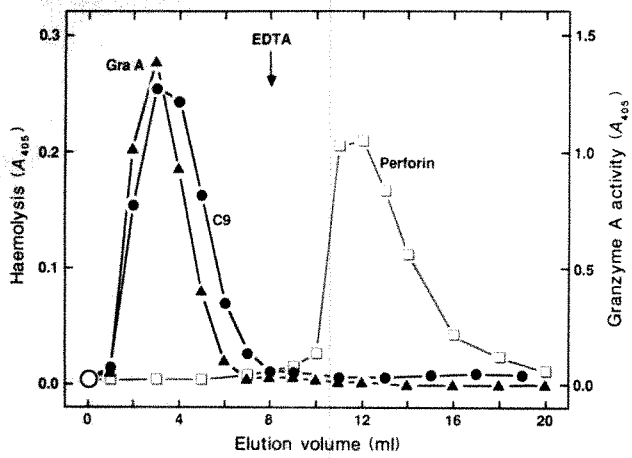

Fig. 2 Binding of perforin to a phosphorylcholine-Sepharose column. Purified perforin, an extract of granule proteins (perforin and granzyme A activity were determined) or C9 were passed over a phosphorylcholine-Sepharose column.
Methods. Phosphorylcholine affinity resin was prepared by reacting p-diazonium phenylphosphorylcholine with glycyltyrosine-conjugated Sepharose 4B as described previously[24]. Perforin and granule extracts were isolated from granules of the CTL line B6.1 (ref. 25). Granules were routinely isolated from 5×10^8 B6.1 cells. Cells were broken by nitrogen cavitation, and the organelles were separated on a discontinuous Percoll gradient. Soluble granule extracts were prepared by adding 1.5 M NaCl, thereby disrupting the granules[25]. Perforin or granule extracts were dialysed overnight at 4 °C against TBS containing no calcium. 100 μl aliquots were passed over a 2 ml phosphorylcholine-Sepharose column equilibrated in TBS containing 5 mM $CaCl_2$. Perforin was eluted with TBS containing 10 mM EDTA. Perforin activity was determined as described above. The esterolytic activity of granzyme A was assayed using benzoyl-lysine-thiobenzylester[5]. C9 activity was determined using C5b-8-bearing erythrocytes[7].

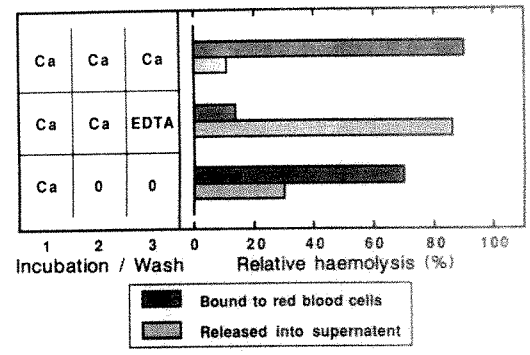

Fig. 3 Binding of perforin to red blood cells. Perforin was incubated in the presence of 5 mM Ca^{2+} with sheep red blood cells and washed and incubated: twice with a buffer containing 5 mM Ca^{2+}; once with 5 mM Ca^{2+} and once with 10 mM EDTA; or twice with 'Ca-free' buffer. The portion of perforin bound to the red blood cells (dark bars) or released into the supernatant (light bars) was determined after the last wash/incubation step.
Methods. 400 μl sheep red blood cells (1.5×10^7 cells ml^{-1}) in GVB containing 5 mM Ca^{2+} were incubated at 0 °C (on ice) during 10 min with a dilution of perforin or granule extracts which was three times higher than that required for 100% lysis at 37 °C after 15 min. No lysis occurred at this point. The cell suspensions were centrifuged and resuspended at 0 °C: twice in GVB containing 5 mM Ca^{2+}; once in GVB containing 5 mM Ca^{2+} and once in GVB containing 10 mM EDTA; and twice in GVB without Ca^{2+} ('Ca^{2+}-free' buffer). This last incubation was for 10 min on ice before the red blood cells were spun down. The pellet of red blood cells was then resuspended in 400 μl fresh GVB containing 5 mM Ca^{2+} and the mixture was incubated at 37 °C for 15 min. Perforin-induced haemolysis was determined as described in the Fig. 1 legend. The haemolytic activity of the unbound/released perforin was assayed by adding the supernatant after the last centrifugation step (300 μl) to 100 μl of concentrated sheep red blood cells (4.5×10^7 cells ml^{-1}) in GVB containing 5 mM Ca^{2+} (or 20 mM Ca^{2+} in the case when EDTA was used in the last wash). Haemolysis was assayed as above. The sum of lysis was arbitrarily considered as 100%.

to phosphorylcholine was also highly dependent on the *p*H, as perforin was retained only above *p*H 6. This is consistent with the *p*H dependence of perforin's lytic activity (Table 1). Neither other granule proteins, that is, granzymes, nor complement C9 bound to the phosphorylcholine-Sepharose (Fig. 2).

Perforin, like C9[16], has been shown to interact with membranes at 0 °C without consequent membrane insertion and lysis[13]. Perforin (or granule proteins) were incubated with red blood cells at 0 °C in the presence of 5 mM Ca^{2+} (Fig. 3). Erythrocytes were then washed twice in Ca^{2+}-containing ice-cold buffer to remove excess perforin and the subsequent increase in temperature to 37 °C led to haemolysis. In contrast, if perforin-bearing erythrocytes were washed in the presence of 10 mM EDTA, haemolysis did not occur. Perforin dissociated from the perforin-bearing erythrocyte membrane, as its activity was found in the supernatant after pelleting the intact erythrocytes. When erythrocytes were transferred into 'Ca^{2+}-free buffer', haemolysis still occurred.

These results indicate that perforin, upon exocytosis and in the presence of Ca^{2+}, binds to phosphorylcholine moieties of the target-cell membrane before lipid insertion and target-cell injury. The identification of the receptor is based on the similarity of the binding characteristics of perforin to phosphorylcholine-Sepharose and to red blood cells, respectively (Table 1). Only the binding, but not the lysis (insertion) step is dependent on the high Ca^{2+} concentrations required for perforin-mediated cytolysis[1,2,4,13]. It is possible that, within the granules, perforin may have endogenously-bound ions (as has been shown for C9[17]) which, upon exocytosis, allow the binding of perforin to the target cells. This may partly explain recent results showing that *in vivo* primed CTL require far less Ca^{2+} than purified perforin for their cytolytic activity[18,19], and that EDTA was unable to completely inhibit CTL-mediated cytolysis, when highly sensitive target cells were used[20,21].

It has been proposed that perforin and C9 have arisen from a common ancesteral gene[7,8]. A lytic protein whose receptor molecule is almost universally distributed on every cell type is potentially very dangerous for the organism. Thus, perforin is stored sequestered in cytoplasmic granules and is only released upon target-cell recognition at the site of close contact between CTL and target cell. In contrast, C9, which circulates in plasma, has lost its capacity to interact with phosphorylcholine and has become dependent on the nascent C5b-8 receptor complex for the proper target-cell recognition. The recent primary structure determination of perforin has shown that no overall homology

Table 1 Characteristics of perforin binding to phosphorylcholine-Sepharose and sheep red blood cells

Characteristics	Half-maximal binding/lysis: PC-Sepharose binding	Red blood cells: binding	Red blood cells: lysis
*p*H	6.5	6.5	6.5 (refs 13, 14)
$[Ca^{2+}]$	0.5 mM	0.5 mM	0.5 mM (refs 1, 4, 13)
$[Ca^{2+}]$*	<1 μM	NA	<1 μM
Mg^{2+}†	neg.	neg.	neg.

Experiments to investigate perforin binding to the phosphorylcholine (PC)-Sepharose or to the red blood cells, respectively were carried out as described in the legends to Figs 2 and 3, respectively, except that the *p*H or the metal ion conditions for the column or incubation buffer were varied. Bis-tris was used instead of Tris-HCl, when the *p*H was below 6.5. Concentration <1 μM stands for 'calcium-free' buffer. NA, not applicable; neg., negligible.
* After binding has occurred.
† 5 mM.

exists between perforin and C9[22,23]. The structural differences at the N and C termini may account for the functional dissimilarity.

We thank E. Burnier, O. Krähenbühl, R. Etges and Z. Freiwald for their help in preparing the manuscript. J.T. is supported by a grant of the Swiss NSF.

A kinetic intermediate in the reaction of an antigenic peptide and I-E^k

Scheherazade Sadegh-Nasseri & Harden M. McConnell

Stauffer Laboratory of Physical Chemistry, Department of Chemistry, Stanford University, Stanford, California 94305, USA

Helper T cells are triggered by molecular complexes of antigenic peptides and cell surface glycoproteins of the MHC (gene products of the major histocompatibility complex) on antigen-presenting cells[1]. There is now a lot of evidence that the complexes between isolated class II MHC molecules and selected peptides have long half-lives of approximately one day[2,3]. The reported equilibrium binding constants between antigenic peptides and class II MHC molecules however, are only micromolar[4,5], suggesting that the association rate constants are very low. The only reported[2] association rate constant is for a chicken ovalbumin peptide (OVA323–339) binding to I-A^d, and is indeed remarkably low, about 1 litre per mole per second. Prompted by these unusual data, we have used the pigeon cytochrome-*c* peptide pCytc(88–104) and I-E^k reconstituted in planar lipid bilayers on glass slides to investigate further the kinetics of peptide–MHC reactions. We report the formation of two IE^k-pCytc peptide complexes. One complex has slow apparent association and dissociation kinetics, very similar to those reported previously for the chicken ovalbumin peptide and I-A^d. The second complex forms and dissociates about a hundred times more rapidly. The short-lived complex shows peptide–MHC specificity and is a kinetic intermediate in the formation of the long-lived complex; the long-lived complex is recognized by specific T-helper cells.

The helper-T-cell hybridoma 2B4 recognizes the class II MHC molecule, I-E^k and the 17 amino-acid C-terminal peptide of pigeon cytochrome-c, pCytc (88-104)[6]. This hybridoma is triggered to produce interleukin-2(IL^{-2}) when pCytc peptide is presented by I-E^k incorporated in planar lipid bilayers on solid supports[7]. Pigeon-Cytc labelled at the N terminus with fluorescein isothiocyanate FpCytc) binds to I-E^k incorporated into planar membranes. The two peptides, pCytc and FpCytc, are almost equally effective in triggering the 2B4 hybriodma (unpublished results). Two protocols were used to study the kinetics of FpCytc binding to I-E^k in planar membranes. In one, the fluorescence intensity attributed to FpCytc-I-E^k complexes was measured as a function of time. A reaction between FpCytc and I-E^k was essentially complete after ~100 seconds when the initial peptide concentration was 80 μM (see Fig. 1*a*). The binding measurements for times less than 100 s are reproducible but are of uncertain significance because of possible mixing artefacts. To test the kinetic order of the reaction a second protocol was used with series of incubations varying the incubation time (t) and peptide concentration (c) so that the product, (ct) was a constant (Fig. 1*b*). The data are not consistent with a single-step pseudo first-order reaction that goes to completion, as this should lead to a constant amount of complex when (ct) is kept constant.

Table 1 Specificity of the fast reaction between pigeon cytochrome c peptide (88-104) and I-E^k in planar bilayer membranes

Reactants	Photon counts s^{-1}
I-E^k + FpCytc	9,864 ± 625*
I-A^d + FpCytc	< 1,000*
Lipid + FpCytc	< 1,000*
I-E^k + α I-E^k, then FpCytc	1,100†
I-E^k + α I-A^k, then FpCytc	9,860†
I-E^k + pCytc, then FpCytc	1,300‡

*Incubation was with 80 μM FpCytec for 2 min.
† Preincubation with anti-MHC antibody was for 5 min, then washed and 80 μM FpCytc added.
‡ 80 μM pCytc was incubated with I-E^k in planar membranes for 2 min and FpCytc was then added for another 2 min, then washed with PBS.

The rapid reaction of fluorescent peptide and I-E^k was found to be specific, as (1) fluorescent OVA peptide did not bind to I-E^k, (2) preincubation with an antibody specific for I-E^k inhibited rapid binding of FpCytc to I-E^k whereas the non-specific antibody (anti-I-A^k) did not, and (3) preincubation of unlabelled pCytc with the I-E^k-containing planar membrane inhibited rapid binding of FpCytc peptide (see Tables 1, 2). The number of I-E^k molecules per unit area in the membrane (~3×10^{11} cm^{-2}) corresponds to the number of I-E^k molecules used in the preparation of the I-E^k-containing vesicles, and was confirmed using fluorescinated anti-I-E^k antibody. In the experiments reported here the number of fluorescent peptides bound at maximal binding exceeded 50% of the I-E^k in the planar membrane. In a number of other experiments the maximum fluorescent peptide binding was so low (~10%) that it precluded kinetic measurements, because of a reduced signal: background ratio.

In the cellular assay, we measured the extent of T-cell stimulation (IL-2 secretion) as a function of the number of preformed complexes. The number of preformed complexes was established by incubation time and peptide concentration. The planar membranes containing the resulting I-E^k-peptide complexes were then washed, and T cells added (Fig. 1*c*). Again, the

Table 2 Specificity of the kinetic intermediate complex of pigeon cytochrome *c* and I-E^k

Reactants	Photon counts s^{-1}
I-E^k + FpCytc	5,800
I-E^k + FpCytc (2 min) then pCytc*	3,800
I-E^k + FpCytc (1 min) then pCytc	1,600
I-E^k FpCytc (2 min) then OVA	4,600
I-E^k + FpCytc (1 min) then OVA	4,300

Experimental conditions as described in Fig. 1*a* legend.
* Unlabelled peptides were incubated for 2 min at a concentration of 100 μM.

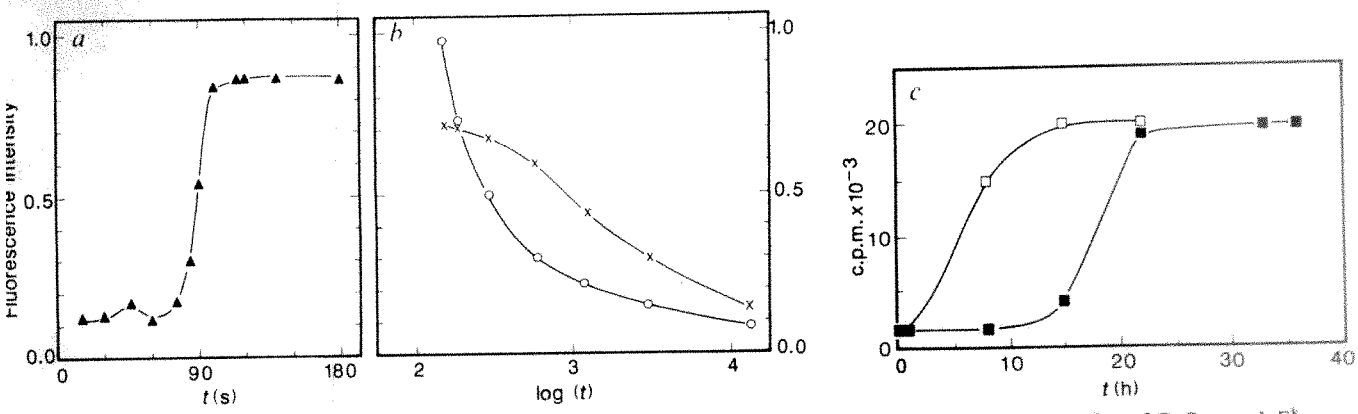

Fig. 1 Kinetics of binding of FpCytc to I-E^k in planar bilayer membranes. *a*, *b*, Fluorescence assays for the binding of FpCytc to I-E^k. *a*, Fixed 80 μM concentration of peptide versus incubation time. Fluorescence intensity is in units of 10^4 photons s^{-1}. Data are corrected for non-specific background, which is 30–40% of total signal. *b*, Fluorescence intensity is relative to the peak intensity. ○, FpCytc at concentration *c* incubated for time *t*, such that $tc = 12 \times 10^3$ μM s. X indicates theoretical points based[15], on estimated values of the rate constants k_{oi}, k_{io}, k_{ti}, k_{io} given in the text, using $k_{it} = 4 \times 10^{-5}$ s^{-1}. The values of X give the sum of the concentrations of C_i and C_t. The maximum value of X corresponds to 71% occupation of the available binding sites. A larger value of $k_{it} = 4 \times 10^{-4}$ significantly increases $(C_i + C_t)$ only at the two longest times. *c*, Cellular assay for the kinetics of binding of pCyte to I-E^k. Solutions of 3 μM (■) or 30 μM (□) pCytc were incubated with I-E^k in planar membranes for the indicated times, the membranes washed, 2B4 T cells added, and IL-2 secretion was assayed by [^{3}H]thymidine uptake of the CTLL-2 cell line. The ratio of the two times (5.5 and 18 h) for 50% triggering is used to estimate the equilibrium dissociation constant K_i for the intermediate complex. The absolute value of each half-time can be used to estimate the rate constant k_{it} for the unimolecular transition of the intermediate complex to the terminal complex under the assumption that 50% of maximal T-cell triggering corresponds to 50% occupation of available I-E^k peptide binding sites. Competition experiments show that the half times in these experiments do not depend on the number of available I-E^k binding sites (unpublished results). This analysis is equivalent to drawing first-order binding curves through the mid-points of the experimental data, and assuming that the deviation of the data from these curves is due to non-linearity in T-cell responses. **Methods.** I-E^k was purified by affinity chromatography using monoclonal antibody 14-4-4S as described[9,10]. Lipopolysaccharide (*Escherichia coli* 0.111:84, Difco) stimulated blast cells from spleens of CBA (H-2^k) mice were used as the source of I-E^k. Reconstitution of I-E^k into planar membranes was as described[10]. Vesicle preparations for cellular assays used the lipid mixture of dipalmitoylphosphatidylcholine and dilinoleoyl phosphatidylcholine and cholesterol[7]. In *a*, 80 μM FpCytc was incubated with planar membranes containing I-E^k for the times indicated, then washed for one minute with PBS, all at room temperature (20 °C). Fluorescence intensity was measured with the photon counting system described previously[8]. The incubations were carried out in chambers of 20 μl volume assembled on a quartz microscope slide and covered by a circular 12-mm diameter coverglass using two layers of double sticky tape. Each microscope slide had two chambers. Vesicle preparations with or without I-E^k were deposited in the chambers, allowing planar membrane formation. N-terminal fluorescination of pCytc (88–104) was carried out during solid phase peptide synthesis (Peninsula), and purified by reverse phase HPLC on a Vydac C_{18} column. In *c*, the cell-free reaction took place during time intervals shown. Excess unbound peptide was removed by careful replacement of the medium covering the planar membrane, over a period of 10 min or more. T cells were added at a density of 4×10^5 to every well. The amount of IL-2 secreted in culture wells was assayed by [^{3}H]thymidine uptake of an IL-2-dependent T-cell line CTLL-2.

binding kinetics cannot be accounted for by a single-step pseudo first-order reaction. That is, the times for 50% cell triggering are not inversely proportional to the peptide concentration.

The experiments in Fig. 2 (▲) show the dissociation of the FpCytc-I-E^k complex as a function of time. FpCytc and I-E^k in planar membranes were incubated at room temperature for various lengths of time and were then sequentially rinsed to remove dissociated FpCytc. The wash was repeated at the indicated times for 2.5 days. After many washes the samples lose only 5–10% of the I-E^k as judged by the binding of anti-I-E^k. The dissociation curve is evidently biphasic with fast and slow components. Both reactions follow first-order kinetics with half lives of approximately 10 minutes and of 30 hours. The half life for the dissociation of pCytc from I-E^k at 37 °C obtained from the cellular assay is similar: 34 hours (Fig. 2, ●).

The dissociation data can be understood semiquantitatively in terms of two complexes of FpCytc and I-E^k, a short-lived intermediate complex C_i and a long-lived terminal complex C_t.

$$\text{FpCytc} + \text{I-E}^k \underset{k_{io}}{\overset{k_{oi}}{\rightleftharpoons}} C_i \underset{k_{ti}}{\overset{k_{it}}{\rightleftharpoons}} C_t \qquad (1)$$

The first-order dissociation rate constant for the intermediate of FpCytc complex in Fig. 2*a* is $k_{io} = 1.2 \times 10^{-3}$ s^{-1}. The first-order dissociation rate constant for the long-lived terminal complex is $k_{to} \approx k_{ti} = 6.3 \times 10^{-6}$ s^{-1}. The relative amplitudes of the slow and fast components of dissociation depend on the time of preincubation before the dissociation measurement. The longer incubation time gives a larger proportion of the slowly dissociating component. Thus a 5-min incubation gives ~15% of the slow component, whereas a 20-min incubation gives ~30% of the slow component, both with 80 μM FpCytc.

These results can be interpreted using a first-order rate constant for the conversion C_i to C_t of $k_{it} = 4 \times 10^{-4}$ s^{-1}. The data in both Fig. 1*c* and Fig. 2 provide evidence that C_i is an intermediate in the formation of C_t and is not some irrelevant dead-end complex. The experiments do not show whether C_i is a complex with only one bound peptide (FpCytc) or two peptides (for example, FpCytc and a second peptide). The slowly decaying component C_t can be identified as biologically active, given the excellent agreement of the low off-rates based on the fluorescence and cellular assays (Fig. 2, ●).

According to reaction (1) the resultant kinetics of the formation of the terminal complex C_t from peptide and I-E^k are pseudo first-order with a rate constant that is non-linear in the peptide concentration, $k_{ot} = (k_{it})/(p + K_i)$, where p is the peptide concentration and K_i is the dissociation constant of the intermediate complex C_i. The data in Fig. 1*c* can be interpreted with $K_i \approx 10^{-5}$ M and $k_{it} \approx 4 \times 10^{-5}$ s^{-1}; this value for k_{it} assumes the cellular response is half-maximal at 50% saturation of the I-E^k with pCytc. The disparity between the two estimates of k_{it} is not unreasonable in view of the uncertainties in this assumption. We estimate the equilibrium dissociation constant K_t of the terminal complex from the equation $K_t = (k_{ti}/k_{it})K_i$ and obtain $K_t \sim 10^{-6}$–10^{-7} M, depending on the choice of k_{it} from the above estimates. Complexes of other antigenic peptides and Ia studied by Babbitt and co-workers[4] and Buus and co-workers[5] have dissociation constants $K_t \sim 10^{-6}$ M. Our model reduces mathematically to that of Buus at low peptide concentrations ($p \ll K_i$) where only three constants are observed, K_t, k_{ot} and k_{to}.

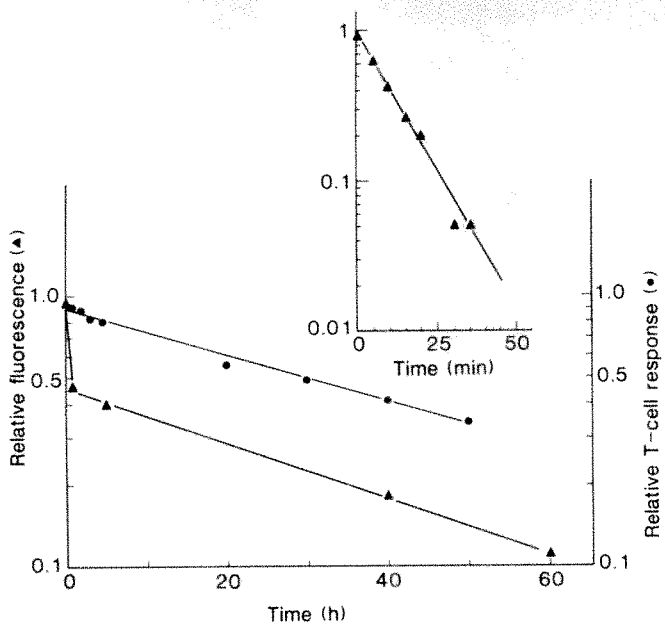

Fig. 2 Kinetics of dissociation of pigeon cytochrome-*c* peptide (88–104)-I-E^k complex. Fluorescence assay, ▲, curve and insert). Following an ~25 min incubation of I-E^k in planar membrane together with 80 μM FpCytc, the sample was washed sequentially at the indicated times. Each wash lasted about 1 min, and involved flowing 10–15 volumes PBS through the sample chamber. The data given in the insert were obtained after a 5-min incubation. Fluorescence intensities in the insert are used to estimate the off-rate constant k_{io} for the intermediate complex, and are corrected for both background fluorescence and the fluorescence intensity of the long-lived complex. After this 5-min incubation the short lived fluorescence (10-min half-life) is about 85% of the total specific fluorescence. The half-time for the dissociation of FpCytc from the terminal complex from the fluorescence data is 30 hours. In the cellular assay, (●) 15–20 μM unlabelled peptide was incubated at 37 °C with planar membranes with I-E^k for 24 h in RPMI medium without serum. Excess unbound peptide was removed. Each data point was obtained by allowing dissociation of peptide from I-E^k–peptide complexes followed by a second rinse before addition of 2B4 T cells in 10% fetal calf serum. The half time obtained from these cell assay data is 34 h. At each time point, the proliferation of CTLL was measured by titrating the supernatant and using data in the linear range.

The kinetic scheme (1) does not account for the observed but uncertain shape of the short time (<100 s) binding curve. A value of $k_{oi} = 1.2 \times 10^2$ l mol^{-1} s^{-1} obtained from the above estimates of K_i and k_{io} leads to a half-time for the formation of C_i of 70 seconds at 80 μM peptide, a result close to the onset time of ~90 seconds seen in Fig. 1*a*. These estimated values of K_i and k_{oi} also lead to the calculated points X in Fig. 1*b*, to be compared with the experimental points O. The calculations used the solution for two sequential first-order reactions given by Moore and Pearson[15]. At short times and high peptide concentrations the fraction of the available I-E^k binding sites occupied by the peptide is approximately $pk_{oi}k_{ii}t^2$, so that even at times as short as 100 s as much as 1% terminal complex can form, which may account for some of the very recent observations on the kinetics of peptide–MHC complex formation, as measured by calcium influx in specific T cells[16].

In summary, a variety of kinetic data all point to the formation of an intermediate complex between an antigenic peptide and an MHC molecule. This result is particularly significant as the intermediate complex shows peptide-MHC specificity. The molecular structures of the intermediate and terminal complexes may be very different as the time required for the unimolecular conversion of the intermediate complex to the terminal complex is long, estimated to lie between 30 and 300 min. The slow step may or may not involve the release of a second peptide. Thus, although specific helper T cells presumably recognize the structure of the terminal complex, the selective peptide recognition by MHC may involve a substantially distinct protein-peptide conformation[12–14].

We thank Dr Gary Fathman for the use of his cell harvester, and Dr Benno Rothenhäusler for bringing ref. 15 to our attention. This work was supported by the NIH. S.S.N. is a recipient of Cancer Research Institute Fellowship award.

The nuclear envelope is a selective barrier against the movement of macromolecules between the nucleus and cytoplasm[1]. Nuclear proteins larger than relative molecular mass 20,000–40,000 are probably actively transported across the envelope through the nuclear pore complex[2,3] and are directed by specific nuclear location sequences (NLS) in the proteins[4]. NLS mediate the nuclear import of isolated nuclear proteins after microinjection into whole cells[5,6] and the nuclear accumulation of chimaeric proteins[7–9] or of non-nuclear proteins conjugated to synthetic peptides[10–12]. The best-characterized NLS is the simian virus 40 large T-antigen sequence[4,13,14]. We have identified two proteins of rat liver by chemical cross-linking that interact with a synthetic peptide containing this sequence: this interaction is specific for a functional NLS, is saturatable, and high affinity. The binding proteins are present in a post-mitochondrial supernatant, in nuclei and in a nuclear envelope fraction, which is consistent with a role in the transport of nuclear proteins from the cytoplasm to the nucleus.

Chemical cross-linking with disuccinimidyl suberate of a radioiodinated synthetic 34-residue peptide from the SV40 large T antigen containing the NLS was used to identify the proteins in different subcellular fractions of rat liver that interact with the NLS (Fig. 1). A 10-residue synthetic peptide containing the wild-type NLS sequence was used as a competitor to define binding specificity. Two proteins that interact specifically with the NLS, and can be competed out by a 100-fold molar excess of the 10-residue wild-type peptide, are detected in a post-

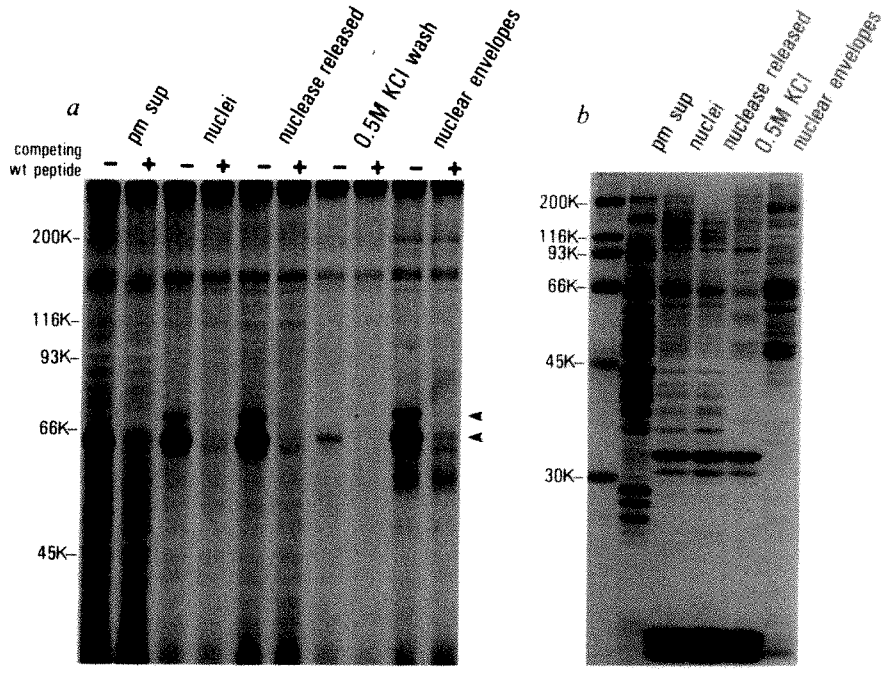

Fig. 1 Intracellular distribution and specificity of the SV40 large T antigen nuclear location sequence binding proteins. *a*, Equivalent amounts of protein from octylglucopyranoside/high salt extracts of post-mitochondrial supernatant (pm sup, 0.05 nuclear equivalents (n.e.) where 1 n.e. = 3×10^6 nuclei), whole nuclei (0.68 n.e.), nuclease-released soluble (1 n.e.), 0.5M KCl-wash (8.7 n.e.) and nuclear envelopes (14 n.e.) were incubated with radiolabelled peptide and cross-linked with disuccinimidyl suberate (Pierce). An autoradiograph of the sodium dodecyl sulphate-polyacrylamide gel electrophoresis (SDS-PAGE) gel is shown. Arrows indicate specific bands. *b*, Coomassie-blue-stained gel of the subcellular fractions used in *a*. The lower portion of the figure presents the sequences of peptides used for cross-linking and competition. The underlined residues represent the minimum SV40 large T antigen nuclear location sequence. The 34-residue peptide was labelled with ^{125}I. Molecular weights of marker proteins are indicated.

Methods. Rat liver nuclear envelopes were prepared as described[17]. Post-mitochondrial supernatant was prepared by centrifugation of the first post-nuclear supernatant at 12,500*g* for 15 min. Portions of each fraction containing 50 μg protein were incubated in 20 μl buffer A (15 mM HEPES-KOH, *p*H 7.3, 0.25 mM $MgCl_2$, 8.5% sucrose, 1 μg ml^{-1} each leupeptin and pepstatin A, 2 mM dithiothreitol, 10 u ml^{-1} aprotinin) 1% octyl-β-D-glucopyranoside (Calbiochem) and 300 mM KCl for 1 hour on ice. The extracts were diluted sixfold in buffer A and 50 nM ^{125}I-labelled SV40 large T antigen peptide or the 10-residue peptides was added to 5μM for competition. The 34-residue analogue was labelled with ^{125}I using Iodogen (Pierce) to a specific activity of $3\text{–}5 \times 10^5$ c.p.m. ng^{-1} peptide. After 30 min at 25 °C, the samples were cooled on ice for 5 min and disuccinimidyl suberate was added to 0.5 mM from a 50 mM stock in dimethylsulphoxide. Cross-linking was terminated after 15 minutes by precipitation with trichloracetic acid added to 10%; precipitates were collected by centrifugation, washed with 95% acetone and air-dried before resuspension in SDS-PAGE sample buffer. Samples were resolved in 8% SDS-PAGE gels[18]. The gel in *b* is 11% polyacrylamide, rather than 8%, which resolves the histones in the nuclear fractions. The gels were fixed and stained with Coomassie blue, destained and dried before autoradiography using Kodak XAR-5 film with an intensifying screen at −80 °C.

mitochondrial supernatant, in nuclei and in a highly purified nuclear envelope fraction by the cross-linking procedure (see arrows in Fig. 1*a* and *b*): these are a predominant protein of relative molecular mass (M_r) 60,000 (60K) and a minor protein of 70K (these values include the mass of the cross-linked peptide). The 70K protein in the post-mitochondrial supernatant can be difficult to visualize (as in Fig. 1), but usually is evident (data not shown). Isolation of nuclear envelopes is by nuclease digestion of nuclei to give a nuclease-released fraction (Fig. 1), followed by extraction in 0.5M KCl to solubilize residual chromatin (0.5M KCl wash, Fig. 1). Most of the NLS-binding proteins are released from nuclei by nuclease digestion, which is consistent with a partially intranuclear location. In different experiments, however, we find that 10–30% of the nuclear-binding activity is retained in the nuclear envelope fraction in a salt-resistant fashion. This indicates that at least a fraction of the NLS-binding proteins are associated with the nuclear envelope. The activity detected in the post-mitochondrial supernatant fraction is probably not a result of release of the proteins from the nucleus during preparation, because isolated nuclei incubated at 4 °C for several hours in the homogenization buffer do not release the binding proteins (data not shown). The binding proteins in the post-mitochondrial supernatant are retained in a high-speed supernatant and therefore are not associated with any membranes (data not shown). Although these data suggest that the location for NLS-binding proteins is partially cytoplasmic, definitive localization requires antibodies specific to these proteins for immunocytochemistry.

To detect the NLS-binding proteins optimally in nuclear envelopes, it was necessary to extract them with 1% octyl-β-D-glucopyranoside/0.3M KCL before cross-linking (Fig. 2). Substantially more cross-linking of the peptide to the NLS-binding proteins was seen in the detergent-soluble fraction (Fig. 2,OCG/KCl in lane S) compared with intact nuclear envelopes (buffer), with essentially no detectable binding protein remaining in the insoluble lamina fraction (OCG/KCl, lane P). The reason for this binding 'latency' is unclear. As these detergent and salt conditions completely solubilize some nuclear pore complex proteins[15] (data not shown), it is possible that the masked binding activity represents NLS-binding proteins associated with endogenous transport ligands which become dissociated in the presence of detergent and high salt. In contrast to nuclear envelopes, treatment of the other subcellular fractions with detergent and salt resulted in only a small increase in the binding proteins detected (data not shown).

The 60K and 70K labelled proteins were present in the same relative abundance in all subcellular fractions, but their relationship is unknown. The association of the synthetic peptides with

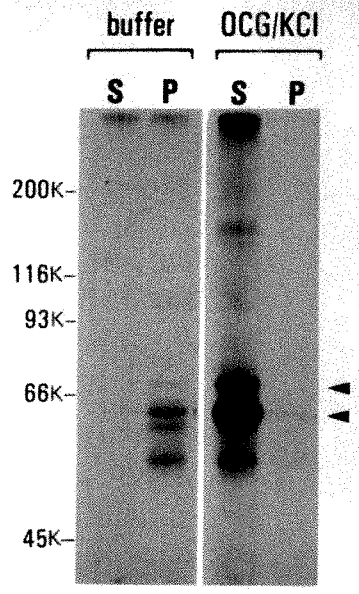

Fig. 2 Extraction of SV40 nuclear location sequence binding protein from nuclear envelopes. The binding proteins are masked in the nuclear envelope (buffer) but can be exposed by extraction in 1% octyl-β-D-glucopyranoside/0.3M KCl (OCG/KCl). Detergent-soluble (S) and insoluble material (P) after extraction and cross-linking are shown on an autoradiograph of the SDS-PAGE gel.

Methods. 50 μg nuclear envelopes were incubated in buffer A containing 50 mM KCl (buffer) or 1% OCG/300 mM KCl (OCG/KCl) as described in Fig. 1 legend. Soluble and insoluble fractions were separated after cross-linking by centrifugation at 5,000*g* for 15 min.

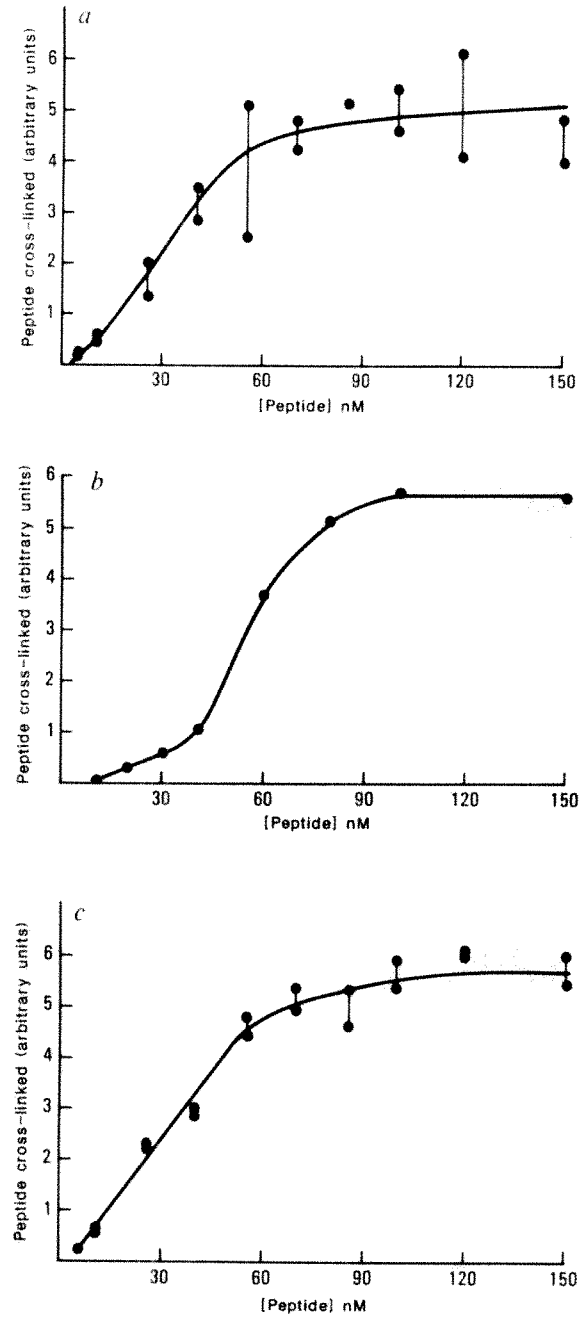

Fig. 3 Saturatable, high-affinity binding of the NLS peptide to the NLS-binding proteins. Cross-linking to (*a*) post-mitochondrial supernatant, (*b*) nuclease-released material or (*c*) nuclear envelopes demonstrates that the binding is saturatable and of high affinity. Data represent quantitation of the 60K protein; equal amounts of protein were analysed for each fraction.

Methods. Subcellular fractionation and cross-linking are as described in Fig. 1. Autoradiographs were scanned in an LKB Ultroscan XL laser densitometer. Peak areas were integrated automatically and used to plot the relative amount of radioactivity in each band. Arbitrary units were assigned to the nuclear envelope fraction and the values for the other fractions were adjusted to give similar values at saturation. Samples were run in duplicate, with the exception of the nuclease-released fraction which was determined once at each peptide concentration. Cutting individual bands from the gels and counting in a gamma counter gave similar results.

the binding proteins occurs rapidly, reaching equilibrium within minutes at 25 °C, and does not require ATP (data not shown). The binding proteins associated with the solubilized nuclear envelope (Fig. 2) are not immunoadsorbed with monoclonal antibodies to nuclear pore complex glycoproteins[15] and are therefore distinct from them (data not shown).

We used the peptide cross-linking assay to test the concentration dependence of the interaction of the 60K protein with the 34-residue peptide (Fig. 3). Saturation was achieved in all fractions at 50–75 nM peptide concentrations, which indicated a high-affinity interaction. The binding curves for the post-mitochondrial supernatant (Fig. 3*a*) and the nuclear envelope (Fig. 3*c*) material are hyperbolic, reaching half-maximal saturation at 30 nM peptide, whereas the nuclease-released (Fig. 3*b*) material gives a sigmoidal curve, with half-maximal saturation at almost 60 nM peptide. Whether this represents a true difference in binding properties or results from other differences between the fractions is unknown.

The specificity of binding was further analysed by competition with peptides containing sequences previously characterized by their ability to direct nuclear transport *in vivo*[14,16]. A 10-fold and 100-fold molar excess of each peptide was used to compete with specific binding of the 34-residue NLS peptide (Fig. 1*c*) in the cross-linking assay. A peptide containing the wild-type NLS (Fig. 4, wild type), as well as a peptide containing a mutation that does not affect transport *in vivo* (peptide A) strongly compete for binding with the NLS peptide. A peptide containing a mutation that abolishes transport *in vivo* (peptide B) does not inhibit binding, whereas two peptides containing sequences that allow partial transport compete weakly or not at all (peptides C and D). The observed competition with peptides containing transport-competent sequences is not a simple consequence of charge density on the peptides, as a peptide containing the reverse of the wild-type sequence (that is, from

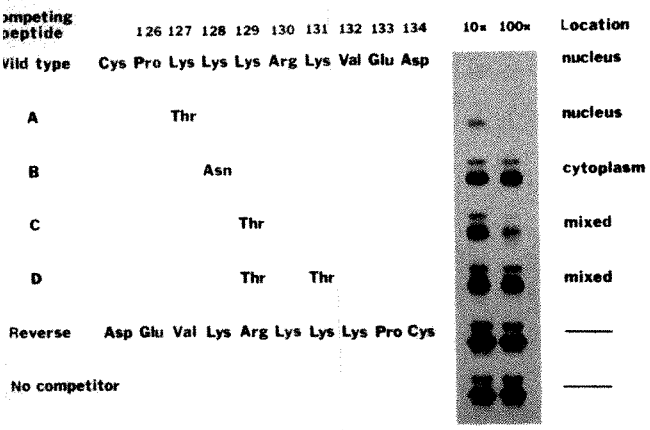

Fig. 4 Specific binding of the NLS peptide to the NLS-binding proteins. Cross-linking was as described in Fig. 1, using binding proteins extracted from nuclear envelopes. Cross-linking in the presence of 10-fold and 100-fold molar excess of competing peptides is shown. Subcellular locations were taken from ref. 14.

Methods. Wild-type, B and reverse peptides, as well as the 34-residue peptide, were synthesized by the stepwise coupling of activated protected amino acids by the solid-phase peptide synthesis method[19] on to 4-methylbenzhydrylamine resin using an Applied Biosystems 430A automated peptide synthesizer. The peptides were cleaved from the resin by liquid HF at 0 °C for 1 hour in the presence of anisole[19]. The 34-residue analogue was cleaved by the low/high HF method[20], modified to include cysteine-HCl. The crude peptides were purified by HPLC on Vydac RP-C18 or RP-C4 preparative columns using a water/acetonitrile-containing 0.1% trifluoroacetic acid (gradient 100/0 to 50/50). Peptides A, C and D were synthesized by the simultaneous multiple-peptide synthesis method[21] and were not further purified for this analysis. All peptides were further purified by chromatography on Sephadex G-10 in 0.1M acetic acid and concentrations of each were determined by Ellman's reaction[22].

arboxyl to amino residues) does not compete for binding (peptide reverse). Thus there is a close correspondence between the bility of different sequences to direct transport *in vivo* and their bility to compete with NLS-peptide binding to the 60K and 0K proteins *in vitro*.

These cross-linking experiments identify only two proteins in at liver that specifically interact with the SV40 large T antigen uclear location sequence. As the interaction is also high-affinity nd saturatable, it is most likely that the NLS-binding proteins ve have detected represent carrier molecules for nuclear import f proteins containing a functional SV40 large T-antigen NLS. he apparent distribution of these proteins in the cytoplasm nd nuclear interior as well as in the nuclear envelope supports multistep model for carrier-mediated nuclear protein import. he initial step, binding of the protein to be transported to a eceptor in the cytoplasm, could occur very soon after translaion; this receptor–protein complex could then be recognized t the nuclear pore complex by another receptor molecule and e translocated through the pore channel, concomitantly with hannel gating[3]. The internalized complex could then dissociate, vith the free receptor being recycled to the cytoplasm or legraded. Further characterization of the NLS-binding proteins lescribed here in conjunction with *in vitro* and whole-cell uclear transport systems will address some of these possibilities.

We thank Dr Richard Houghten and Linda L. Maggiora for ynthesis of some of the peptides, and Drs J. Glass and . Featherstone for discussion and comments on the manuscript. .A.A. was supported by the Damon Runyon–Walter Winchell ancer Research Fund. This work was supported by a grant rom the American Cancer Society to L.G.

Note added in proof: The reverse sequence peptide in Fig. 4 has ecently been shown to be incapable of directing nuclear transport *in vivo* (T. J. Lobl, personal communication).

Role of transcriptional interference in the *Drosophila melanogaster* *Adh* promoter switch

Victoria Corbin & Tom Maniatis

Harvard University, Department of Biochemistry and Molecular Biology, Cambridge, Massachussetts 02138, USA

The *Drosophilia melanogaster* alcohol dehydrogenase (*Adh*) gene is transcribed from two closely linked promoters[1,2], which are regulated by two upstream enhancers. The proximal promoter is active primarily in first to early third-instar larvae, whereas the distal promoter is active in late third-instar larvae and adults (Fig. 1). The *Adh* larval enhancer and the proximal promoter are separated by the *Adh* adult enhancer and the distal promoter. Because the proximal promoter is turned off just as the distal promoter is turned on, we considered the possibility that the distal promoter or adult enhancer has a role in the downregulation of the proximal promoter. We report here that transcription from the distal promoter is required to shut off the proximal promoter. In the absence of the distal promoter, the proximal promoter is active throughout larval development and in adults. The proximal promoter is also aberrantly active in adults when placed upstream of the distal promoter. These results suggest that the developmental switch from proximal to distal promoter is regulated by the stage-specific activation of the distal promoter, and the subsequent repression of the proximal promoter by transcriptional interference[3–8].

Initially we deleted the distal promoter and the *Adh* adult enhancer (AAE) and examined the activity of the proximal promoter at various developmental stages. When the distal promoter and AAE were deleted (Fig. 2) the proximal promoter was not shut off in mid third-instar larvae but, rather, remained active throughout larval development (Fig. 3*a*, compare lanes 4–6 with 11–14). In addition, the proximal promoter was expressed at aberrantly high levels in adults (Fig. 3*a*, compare lanes 7 and 15). Thus, the distal promoter and AAE are required for the normal downregulation of the proximal promoter in third-instar larvae and in adults.

A deletion that removes the TATA box and initiation site of the distal promoter (−66 to +53), also leads to the derepression of the proximal promoter in adults (Fig. 4*a*, lanes 12–14). This result suggests that readthrough transcription from the upstream, distal promoter inactivates the proximal promoter (transcriptional interference[3–8]). Unlike other systems where transcrip-

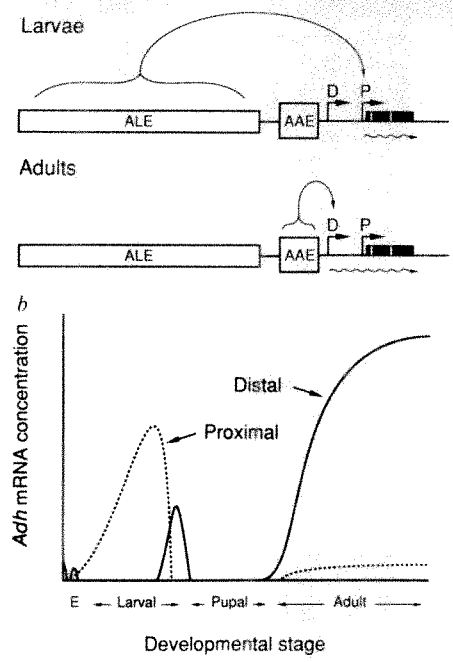

Fig. 1 The organization of *Adh* regulatory sequences and the pattern of *Adh* expression during development. *a*, The *D. melanogaster Adh* gene, showing the enhancer-promoter interactions in different developmental stages. In larvae, the *Adh* larval enhancer (ALE) stimulates transcription primarily from the proximal promoter (V.C. and T.M., manuscript in preparation). ALE activity maps to three disparate regions which lie between −5,000 and −660 base pairs (bp) of the distal promoter (V.C. and T.M., unpublished results). In adults, the *Adh* adult enhancer (AAE) stimulates transcription from the distal promoter[13]. The AAE is located between −590 and −128 bp of the distal promoter (D. Falb and T.M., unpublished observations). *b*, The relative levels of proximal (dotted line) and distal (smooth line) promoter transcripts are plotted as a function of developmental stage (taken from ref. 2).

tional interference has been detected[4,5], deletions that reduced the activity of the upstream (distal) *Adh* promoter, did not proportionately increase the activity of the downstream (proximal) promoter (Fig. 4*a*, lanes 6–11). This observation does not, however, eliminate the transcriptional interference model, as the levels of transcription from the weakened distal promoters are still relatively high and could therefore be sufficient to inactivate the proximal promoter.

To test whether the proximal promoter is repressed in adults by transcriptional interference, we placed a second copy of the proximal promoter and *Adh*-coding region upstream of the AAE and distal promoter, so that transcription from the distal promoter could not read through the upstream proximal promoter (5′*P*3′*D*P, Fig. 2). In this context, the proximal promoter was highly active in adults, even though the distal promoter was expressed at the usual high level (Fig. 4*b*, lanes 7–9). Thus, when transcription from the distal promoter cannot read through the proximal promoter, the proximal promoter is not shut off in adults.

These results are consistent with the transcriptional interference model, but they do not exclude the possibility that the distal promoter, by virtue of its location, blocks interactions between the proximal promoter and the *Adh* larval enhancer (ALE) or the AAE (see Fig. 1*a*; although the AAE does not normally stimulate the proximal promoter, it can if the distal promoter is deleted[13]). We tested this possibility by placing the ALE or AAE at the 3′ end of the gene, so that the distal promoter does not lie between the enhancer and the proximal promoter. The stage-specific expression of the two promoters was not altered when the ALE was placed downstream from the gene (V.C. and T.M., manuscript in preparation). Similarly, the proximal promoter was repressed normally in adults when the AAE was placed downstream from an *Adh* gene containing both promoters. (Fig. 4*b*, lanes 5 and 6). In contrast, the 3′AAE did activate the proximal promoter in adults when the distal promoter was deleted (data not shown). We conclude that the stage-specific activity of the proximal promoter is independent

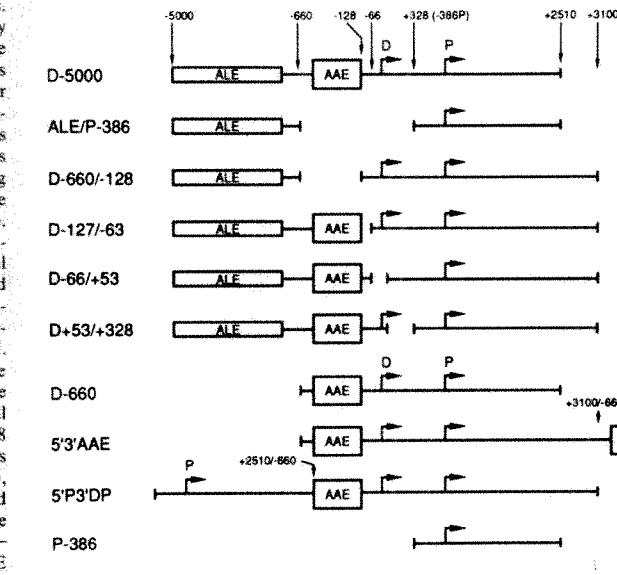

Fig. 2 Structure and expression of mutant *Adh* genes. The structure (not to scale) and transcriptional activity of *Adh* gene constructs in adult transformants are shown. In wild-type adults, the distal promoter is active at high levels (+) and the proximal promoter is active at low levels (−). Different levels of transcripts were observed with independent transformants containing the same *Adh* mutants. This variability is presumably due to the influence of surrounding chromosomal sequences or structure[14]. Therefore, we have indicated the activity of a given gene as a range. N/A, not applicable. Deletion endpoints are numbered relative to the transcription start site of the distal promoter. The enhancers (boxes), promoters (D and P) are indicated. The *D*−5000 gene includes sequences from −5,000 to +2,510 and is expressed at wild-type levels in all developmental stages (V.C. and T.M. manuscript in preparation). The *ALE*/*P*−386 gene contains the ALE fused directly to −386 of the proximal promoter, deleting the AAE and the distal promoter (−386 of the proximal promoter equals +328 of the distal promoter). *ALE*/*P*−386 transformants produce proximal transcripts at levels ~3-fold (1 line), 5- to 10-fold (2 lines), 15- to 20-fold (2 lines), and ~30-fold (1 line) higher than wild-type controls. The internally deleted genes, *D*−660/−128, *D*−127/*D*−63, *D*−66/+53 and *D*+53/+328, remove the ALE (sequences between −660 and −128), sequences just upstream of the distal promoter (between −127 and −63), the distal promoter's TATA box and initiation site (sequences between −66 and +53), and the sequences downstream of the distal promoter (between +53 and +328). In *D*−66/+53 transformants, the activity of the proximal promoter was three-fold (3 lines) or 5- to 10-fold (4 lines) higher than wild-type, although no proximal promoter activity was observed in 2 other lines. *D*−660 contains sequences from −660 to +2,510 (V.C. and T.M. manuscript in preparation). 5′3′*AAE* contains one copy of the AAE in its normal location, and a second copy (−660 to −128) at the 3′ end of the gene (+3,100). 5′*P*3′*DP* contains a duplicate proximal promoter plus *Adh* gene body (+328 to +2,510) linked to a downstream *Adh* gene (−660 to +3,100). *P*−386 contains sequences from +328 (−386 of the proximal promoter) to +2,510 of the distal promoter.
Methods. Standard cloning procedures were used[15]. *Adh* constructs were cloned into the transformation vector Carnegie 20 (ref. 16). Germline transformants were made by injecting the clone of interest and the transposase plasmid, pπ25.7 wc (ref. 17), into ry^{506} embryos[18–20]. Transformants were crossed into the Adh^{fn6}, *cn*; ry^{506} background and established as homozygous stocks[21].

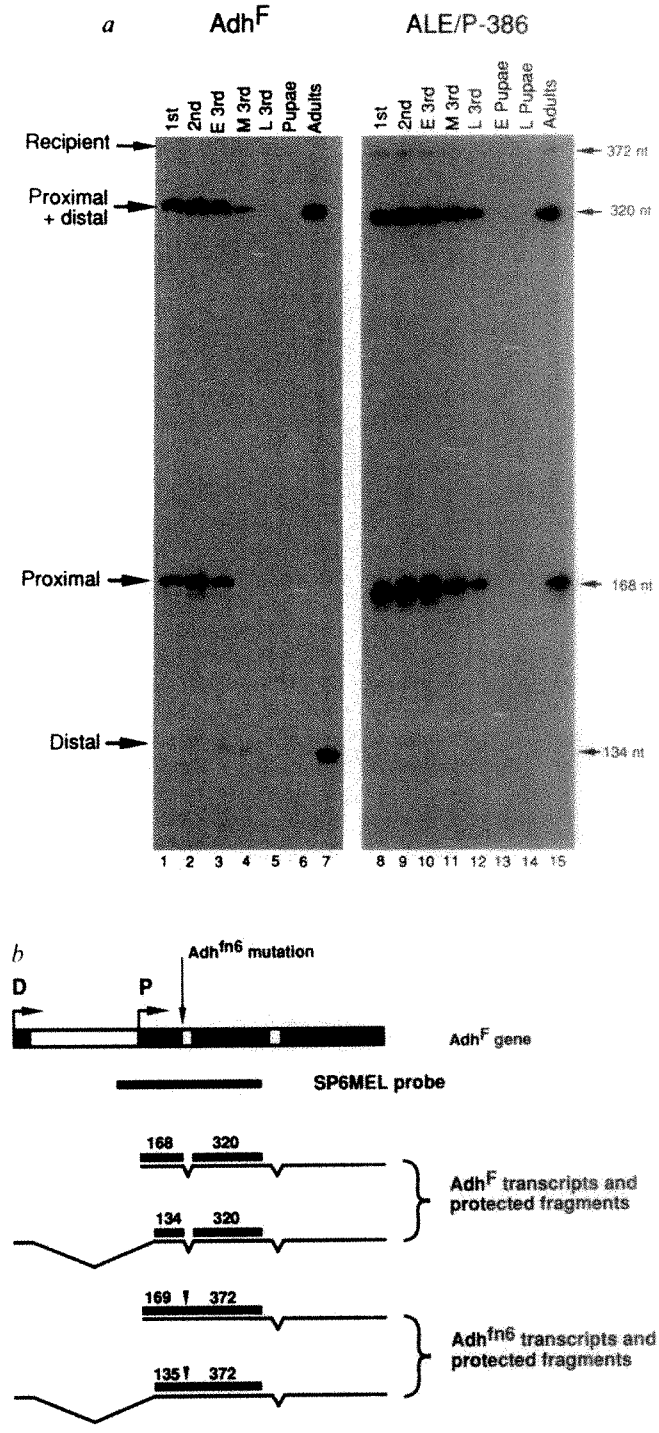

Fig. 3 The proximal promoter is aberrantly active in late third-instar larvae and in adults when the AAE and distal promoter are deleted. *a*, *Adh* transcript levels in *ALE/P−386* transformants were compared to wild-type controls at the indicated developmental stages by RNase mapping[22]. Relevant bands are marked at the side. *b*, Expected products from RNase mapping experiments using the *Adh*-specific probe SP6MEL (ref. 21). The transcribed portion of the Adh^F gene is shown. Black boxes indicate exons; white boxes, introns. The extent of the complementary single-stranded RNA probe, SP6MEL, is indicated by the shaded bar below. Bracketed drawings show RNase-resistant hybrids which form between the probe and transcripts of the transformed (Adh^F) and endogenous (Adh^{fn6}) *Adh* genes. Adh^F transcripts give rise to three protected fragments: a 320-nucleotide (nt) fragment, common to proximal and distal transcripts; a 168 nt fragment, specific to proximal transcripts; and a 134 nt fragment, specific to correctly spliced distal transcripts. Adh^{fn6} transcripts are not spliced properly due to a mutation near the 3′ splice site of the first small intron (marked by arrow)[23]. Distal Adh^{fn6} transcripts yield fragments of 135 and 372 nt; proximal transcripts, fragments of 169 and 372 nt.

Methods. Total nucleic acid was isolated from staged organisms as previously described[21] and hybridized to ^{32}P-labelled RNA probes complementary to *Adh* and α-tubulin transcripts. First, second, early third, mid third and late third-instar larvae were collected 30–42 h, 54–66 h, 66–78 h, 78–90 h and 90–102 h after egg laying, respectively. Early and late pupae were collected 24 and 72 h after the white pre-pupae stage. Adult males were collected 4 days after eclosion. RNA probes were made as described[24], except that bovine serum albumin was added to 10 μg ml^{-1}. RNase mapping experiments were as described[22], except hybridizations were at 37 °C, and the hybrids were digested for 30 min at 25 °C. The products were fractionated on 5% denaturing polyacrylamide gels and visualized by autoradiography.

of the position of the enhancers. The critical factor seems to be the position and activity of the distal promoter. The simplest interpretation of our data is that the distal promoter represses the proximal promoter by transcriptional interference.

Transcriptional interference was first shown to modulate promoter activity in *Escherichia coli*[3,4,8], and subsequently in vertebrates[5–7]. For example, induction of λ-prophage integrated upstream of the *E. coli gal* operon reduces transcription from the P_{gl} promoter[4]. Similarly, when the human α_1 globin gene is duplicated, transcription from the upstream gene inhibits transcription from the downstream gene[6]. Insertion of a transcription terminator between the two genes prevents this inhibitory effect[6]. Although the exact mechanism of transcriptional interference is not known, *in vitro* studies suggest that when RNA polymerase passes through a downstream promoter it can destabilize interactions between that promoter and specific transcription factors[7].

Here, we present evidence that transcriptional interference is important in the promoter switch of the *D. melanogaster Adh* gene. The proximal promoter is repressed in late third-instar larvae and adults apparently by readthrough transcription from the distal promoter. The proximal promoter seems to be sensitive to even low levels of transcription from the distal promoter (Fig. 4*a*, lanes 6–8), which may explain the rapidity of the switch from the proximal to distal promoter in third-instar larvae. Thus, the *Adh* promoter switch seems to be controlled largely or entirely by the stage-specific activation of the distal promoter which, in turn, may be regulated by the stage-specific activity

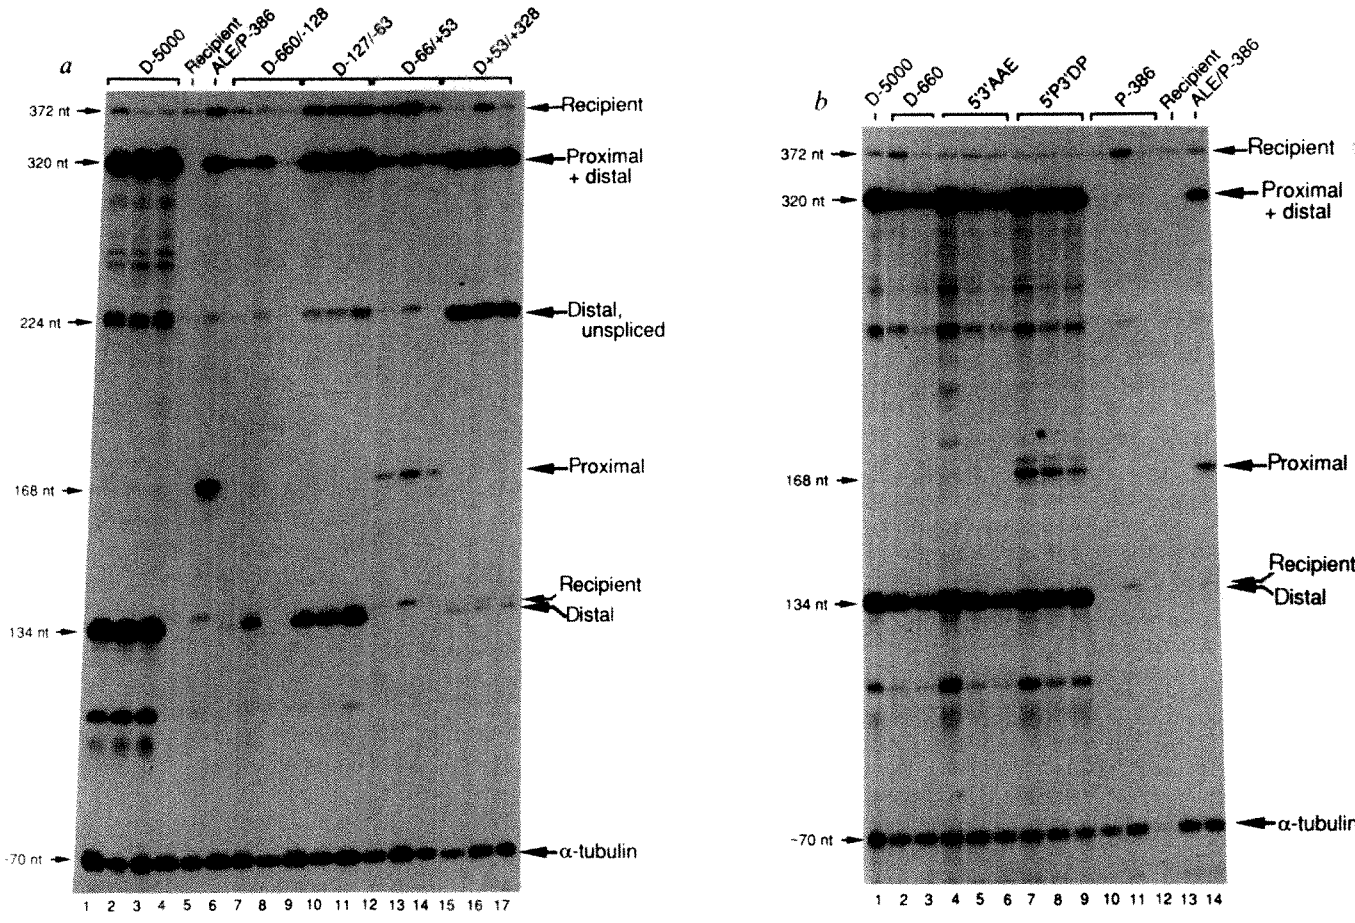

Fig. 4 The distal promoter is required to repress transcription from the proximal promoter in adults. Proximal and distal *Adh* transcripts from adult transformants were quantitated by RNase mapping. Each lane represents an independent transformed line of the indicated genotype. Relevant bands are marked at the side of the autoradiograms. *a*, In the absence of the AAE, the activity of the distal promoter was reduced 8- to 20-fold, but the proximal promoter was active at normal low levels ($D-660/-128$, lanes 6–8). Similarly, the activity of the distal promoter was reduced ~5-fold by the deletion of sequences just upstream of the distal TATA box, but the proximal promoter was unaffected ($D-127/-63$, lanes 9–11). The deletion of the sequence just downstream of the distal promoter did not affect the activity of either promoter ($D+53/+328$, lanes 15–17), although distal transcripts were not properly spliced due to the deletion of the 5′ splice site of the large intron[23]. In contrast, when the distal promoter's TATA box and transcription initiation site were deleted, the proximal promoter was expressed at levels 2- to 10-times higher than normal ($D-66/+53$, lanes 12–14). *b*, Proximal transcripts from *5′P3′DP* were detected at levels 10- to 15-fold higher than controls (compare lanes 7–9 to lanes 1–3). Note that both the upstream and downstream proximal promoters contribute to the pool of proximal transcripts. The downstream proximal promoter, however, is active at extremely low levels in controls (lanes 1–3). Therefore the vast majority of the proximal transcripts must initiate at the upstream proximal promoter.
Methods. Total nucleic acids from adult males were treated as described in Fig. 3 legend.

of the transcription factors that bind to it and the AAE (ref. 9 and V.C., D. Falb and T.M., unpublished observations).

Only one other example of a stage-specific promoter switch has been studied in detail. In the chicken β-globin locus the ε-globin gene is expressed in embryonic erythroid cells, and the closely linked β-globin gene is expressed in adult erythroid cells[10,11]. Recent studies have shown that the ε-globin gene is inappropriately expressed in adult cells if the β-globin gene promoter is deleted[12]. The promoter switch in both the *Adh* and globin systems seem to be regulated by the stage-specific activation of an adult promoter. In the globin locus, however, the ε-globin gene is repressed in adult cells by competing with the β-globin promoter for interactions with a single erythroid cell-specific enhancer[12]. In contrast, the distal *Adh* promoter represses the proximal promoter by transcriptional interference. Thus two distinct mechanisms appear to regulate promoter switching in these two systems.

We thank Bob Cohen, Anne Ephrussi, Sean Munro, Mark Ptashne and members of the Maniatis lab for helpful comments on the manuscript. The work was supported by a grant to T.M. from the NIH.

Mutation rates differ among regions of the mammalian genome

Kenneth H. Wolfe, Paul M. Sharp* & Wen-Hsiung Li†

In the traditional view of molecular evolution, the rate of point mutation is uniform over the genome of an organism and variation in the rate of nucleotide substitution among DNA regions reflects differential selective constraints[1,2]. Here we provide evidence for significant variation in mutation rate among regions in the mammalian genome. We show first that substitutions at silent (degenerate) sites in protein-coding genes in mammals seem to be effectively neutral (or nearly so) as they do not occur significantly less frequently than substitutions in pseudogenes. We then show that the rate of silent substitution varies among genes and is correlated with the base composition of genes and their flanking DNA. This implies that the variation in both silent substitution rate and base composition[3] can be attributed to systematic differences in the rate and pattern of mutation over regions of the genome. We propose that the differences arise because mutation patterns vary with the timing of replication of different chromosomal regions in the germline. This hypothesis can account for both the origin of isochores in mammalian genomes[4] and the observation[5] that silent nucleotide substitutions in different mammalian genes do not have the same molecular clock.

Early estimates of the substitution rates in pseudogenes and at silent sites in protein-coding sequences suggested that pseudogenes evolve more rapidly which implies that silent sites are under some selective constraint[6,7]. However, these studies used very limited data and rather simple methods of estimating rates. Here we use two approaches to compare the rate of substitution in functionless DNA (that is, in pseudogenes and intergenic regions) with that at silent sites in genes; the latter is measured in terms of the number of nucleotide substitutions per fourfold degenerate site (designated K_4). First, we compare the divergences in pseudogenes and in functional genes across the same species pair. If silent sites in functional genes are selectively constrained, then they should have accumulated fewer substitutions.

By far the most substantial data set available is for DNA sequences from humans and Old World monkeys (Table 1). The mean degree of divergence at silent sites is clearly not lower than that in pseudogenes. There are rate differences among genes, but for only one gene (β-globin) out of 13 is the silent rate significantly lower than the pseudogene rate, suggesting that the β-globin rate is an extreme random deviate. Nevertheless, perhaps a better method is to compare a recently generated pseudogene with its functional homologue from the same species, using the functional gene from a second species as a reference. This method can be applied to both processed and unprocessed pseudogenes, but is more accurate in the former case because processed pseudogenes can be assumed to become functionless as soon as they are formed. The three LDH-A processed pseudogenes in mouse[8] provide excellent data for this approach because they are reasonably large and because they were produced after the mouse-rat split, so the rat LDH-A gene can be used as a reference. The ratios of the substitution rates in the three LDH-A pseudogenes to the rate at silent sites in the functional gene are 1.1, 0.8 and 0.7. Again, there is little, if any, evidence for a significantly higher rate of substitution in pseudogenes than at silent sites. We therefore conclude that most silent (fourfold degenerate) sites are effectively neutral, and that their substitution rate is a good measure of the mutation rate, because under selective neutrality the substitution rate is expected to be equal to the mutation rate[1].

Total for functionless DNA	0.075 ± 0.004	40.5	4,842

K_4 (the corrected number of substitutions per fourfold degenerate site) was calculated as described in Fig. 1. References to the original DNA sequence data are available on request.
* G+C content at fourfold degenerate sites (%).
† Number of fourfold degenerate sites compared.

Next we focus on the variation among genes in the substitution rate at silent sites (K_4) and show that it is correlated with their G+C content (GC_4). We compare DNA sequences between mouse and rat, first concentrating on the larger genes (those with over 175 silent sites) (Fig. 1*a*). For the 17 genes with $GC_4 \geq 50\%$, K_4 clearly decreases as GC_4 increases (correlation coefficient $r = -0.73$, $P < 10^{-4}$); the highest K_4 is nearly twice the lowest value. On the other hand, there is a significant positive correlation between substitution rate and GC_4 in the A+T-rich genes, though the number of points is small ($r = +0.82$; $P < 0.05$). This latter observation suggests that the low substitution rates in genes with a high G+C content cannot be simply explained by assuming that G and C nucleotides mutate less frequently than A and T nucleotides. On reflection, it is difficult to think of any other reasonable relationship between K_4 and GC_4, although this has not previously been reported. In fact, others have suggested either no systematic variation (in silent substitution rate) among genes[9], or a simple linear relationship between substitution rate and G+C content[10,11]. When smaller genes are included (making a total of 88 genes), the same peaked relationship as that shown in Fig. 1*a* is seen, but the correlation coefficients are decreased because of the stochastic effects (particularly on K_4) of short genes. The above comparison requires no knowledge of the date of speciation, the data set used is large, and the K_4 values are fairly large but far from saturation. The mouse-rat comparison is preferable to a human-rodent comparison because of the shorter timescale involved; some human genes differ considerably in base composition[12] or even in chromosomal map position[13] from their rodent homologues.

The variance of GC_4 in the 23 large rodent genes (Fig. 1*a*) is more than ten times that expected by chance (under a binomial distribution with mean 58.6%), suggesting that the factors determining G+C content are not uniform for all genes. Of course, one might argue that the GC_4 value in any gene is at a particular optimum and that the observed relationship between K_4 and GC_4 is a consequence of selection maintaining that GC_4 value in the face of a mutation rate that is uniform across the genome. But this would require strong selective constraints, whereas we have shown here that silent sites seem to be effectively neutral. Furthermore, the direction of selection on G+C-rich genes

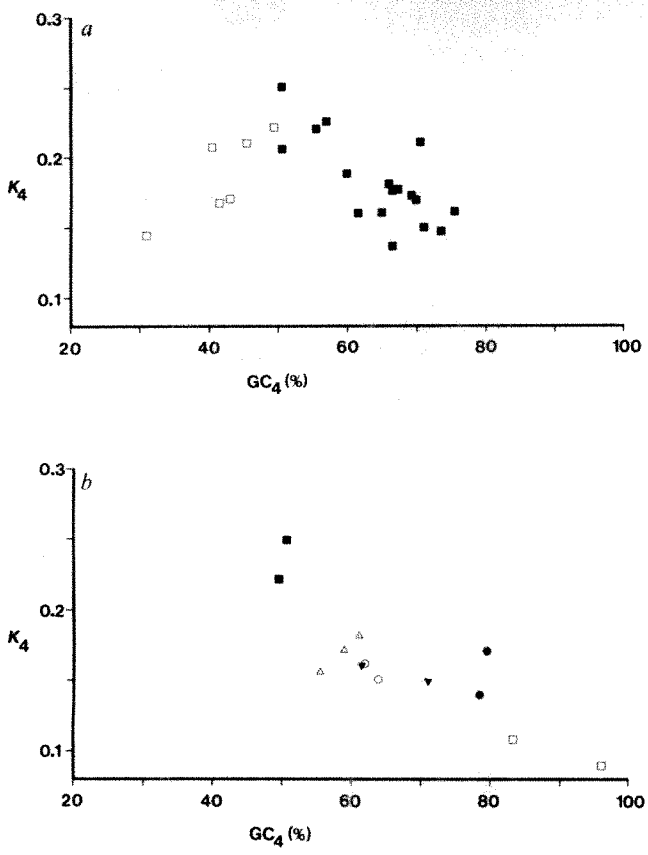

Fig. 1 *a*, Plot of silent substitution rate (K_4) versus G+C content at silent sites (GC_4) for 23 genes compared between mouse and rat. Only large genes (with ≥175 fourfold degenerate sites) are compared. ■, 17 genes for which $GC_4 \geq 50\%$ (encoding alcohol dehydrogenase-1, α-fetoprotein, CD4 antigen, c-*mos* and c-*myc* oncogenes, creatine kinase M, cytochromes $P_1$450 and $P_3$450, β-glucuronidase, malic enzyme, mitochondrial aspartate aminotransferase and malate dehydrogenase, neural cell adhesion molecule NCAM-140, neurofilament M, oestrogen receptor, protein disulphide isomerase and renin); □, 6 genes with $GC_4 < 50\%$ (encoding albumin, α_2-amylase, glucocorticoid receptor, leukocyte common antigen (Ly-5, T200), ornithine decarboxylase and UDP-glucuronosyltransferase). Full references for the sequences are available from the authors on request; all are taken from GenBank (release 50) or the recent literature. K_4 was calculated by the method of Tajima and Nei[30], which requires no assumptions about the base composition of the sequences compared, other than that they be at equilibrium. Any codons at which mouse and rat differed by more than one nucleotide substitution were ignored. This avoided (1) the need to apply weights to the different mutational pathways possible between multiply-substituted codons, and (2) any regions within a gene in which the protein sequences of the two species are considerably different and might not share a common origin (for example as a result of insertions, deletions or alternative splicing). If, as we assume, the sequences being compared have diverged only through a process of random point mutation, ignoring these codons should not alter the synonymous substitution rate calculated. *b*, Relationship between K_4 and GC_4 for several groups of physically linked genes: □, metallothioneins I and II (5 kb apart); ■, albumin and α-fetoprotein (14 kb); ▼, cytochromes $P_1$450 and $P_3$450 (<25 kb); ●, γ_A and γ_D crystallins (35 kb); ○, Ly-2 and Ly-3 antigens (36 kb); △, immunoglobulin heavy chains C_δ $C_{\gamma 3}$ and C_ε (50 kb and 90 kb).

would have to be opposite to that on A+T-rich genes. Thus our finding that the substitution rate and the base composition of silent sites vary together in a systematic way is most simply explained by supposing that the pattern of mutation is different for different genes. Most germline mutations are thought to arise from misincorporation errors made by the DNA replication apparatus[14,15]. It has been demonstrated that different genes replicate at different stages of the cell cycle in differentiated cells[16], and this is presumably also true in the germline. The number and type of replication errors are likely to vary during the cell cycle if the chemical environment in the nucleus changes. In fact, the abundances (both relative and absolute) of free dNTPs in the nucleus change with time[17], as do the activities of the DNA polymerase enzymes and their accessory proteins[18]. We have examined a theoretical model (to be detailed elsewhere) of the relationship between the mutation rate and the G+C content of both the nucleotide precursor (dNTP) pools and the template DNA. This model is based on a simple kinetic description of DNA replication[19], as applied to the replication of long double-stranded DNA molecules. It can explain the occurrence of the maximum mutation rate at an intermediate value of GC_4, provided that GC_4 is positively correlated with the proportion of dGTP plus dCTP in the dNTP pools. This assumption seems plausible as we are considering only effectively neutral sites in DNA. There is also some experimental evidence to support this: as S-phase progresses, the G+C content of both the dNTP pools and the replicating DNA decreases[16,17,20]. As K_4 is a consequence of the mutation rate, under this model the relationship seen in Fig. 1*a* can be generated in the absence of selection.

Replication origins in mammalian DNA are located 50–300 kilobases (kb) apart, and clusters of 12–100 adjacent origins tend to replicate simultaneously[16]. Thus, regions of DNA of 1,000 kb or more could form temporal units of replication, and all DNA within a unit would be expected to show the same pattern and rate of mutation. Thus, under our model, genes which are physically close to each other in the genome should have similar values of K_4 and GC_4. This is indeed the case for those genes for which data are available (Fig. 1*b*): several pairs of genes which are the results of ancient tandem duplications show paired results for K_4 and GC_4, as do genes of the IgH constant-region locus. These IgH genes span 140 kb on mouse chromosome 12, and are known to be part of a single replicon[21].

These replication units seem to correspond to the 'isochores' (large blocks of DNA with homogeneous base compositions) found experimentally in mammalian nuclear DNA[4], and probably also to high-resolution Giemsa chromosomal bands[16]. We therefore propose that isochores arise as a result of the synchronous replication of megabase stretches of DNA under varying dNTP pool conditions. Although our model based on variation in the dNTP precursor pools can provide a simple explanation for the observed variation of mutation rates and patterns around the genome, it is of course not the only possible explanation. For example, Filipski[22] has proposed that isochores are formed as a consequence of the repair of DNA in different types of chromatin by different DNA polymerase enzymes, and there is now some experimental evidence for between-gene differences in efficiency of DNA repair[23]. Our observations could also be explained if DNA is replicated by several distinct DNA polymerase holoenzymes with different error propensities. But recent data indicate that there is only one replicative polymerase complex for mammalian nuclear DNA[18,24].

We conclude that much of the intragenomic variation in silent substitution rate and base composition in mammals results from variation in the process of mutation, rather than from natural selection[25,26]. The implication that silent sites in mammalian genes are effectively neutral contrasts with prokaryotic genes, in which differences in translational efficiency lead to selective differences between codons[27] and thus to lower silent substitution rates in genes that are highly expressed[2]. Our assertion is supported by several arguments, however. First, the base composition of silent sites in mammalian genes is strongly correlated with that of introns and flanking sequences of the same gene[3],

suggesting that it is determined largely by local mutation pressures. In addition, it has recently been suggested on the basis of analysis of dinucleotide frequencies that codon usage in human genes is determined by context-dependent mutational patterns[28]. Second, any suggestion of tissue-specific or expression level-related patterns in mammalian codon usage must be set against the observation that the human α- and β-globin genes have very different codon usage. Third, as the effective population sizes of mammalian species are quite small[29], it would require large selective differences for selection to be effective, but it is unlikely that mammals have sufficient reproductive excess to allow such selection at a very large number of codons. In summary, we propose that, in the mammalian genome, variation in the silent substitution rate and variation in base composition are two facets of the same phenomenon.

We thank D. W. Nebert for cytochrome P_{450} mapping data. This study was supported in part by the European Community BAP (to P.M.S.) and the NIH (to W.H.L).

Nonmutagenic carcinogens induce intrachromosomal recombination in yeast

Robert H. Schiestl

To identify environmental carcinogens there is a need for inexpensive and reliable short-term tests[1], but certain human or animal carcinogens are persistently undetectable as mutagents with the Ames assay[2–5] or with other short-term tests currently in use[6,7]. Thus there is a need for short-term tests which detect carcinogens missed by the Ames assay[1]. Because of the association of carcinogenesis with genome rearrangement[8–12], a system screening for intrachromosomal recombination resulting in genome rearrangement has been constructed in *Saccharomyces cerevisiae*[13]. Evaluation of this system shows inducibility by a variety of carcinogens[3–7] not detectable by the Ames assay or various other short-term tests. In the light of these results it is tempting to speculate that 'nongenotoxic carcinogens' are in fact genotoxic but, in the past, the tools to measure the genetic alterations they induce have been inappropriate.

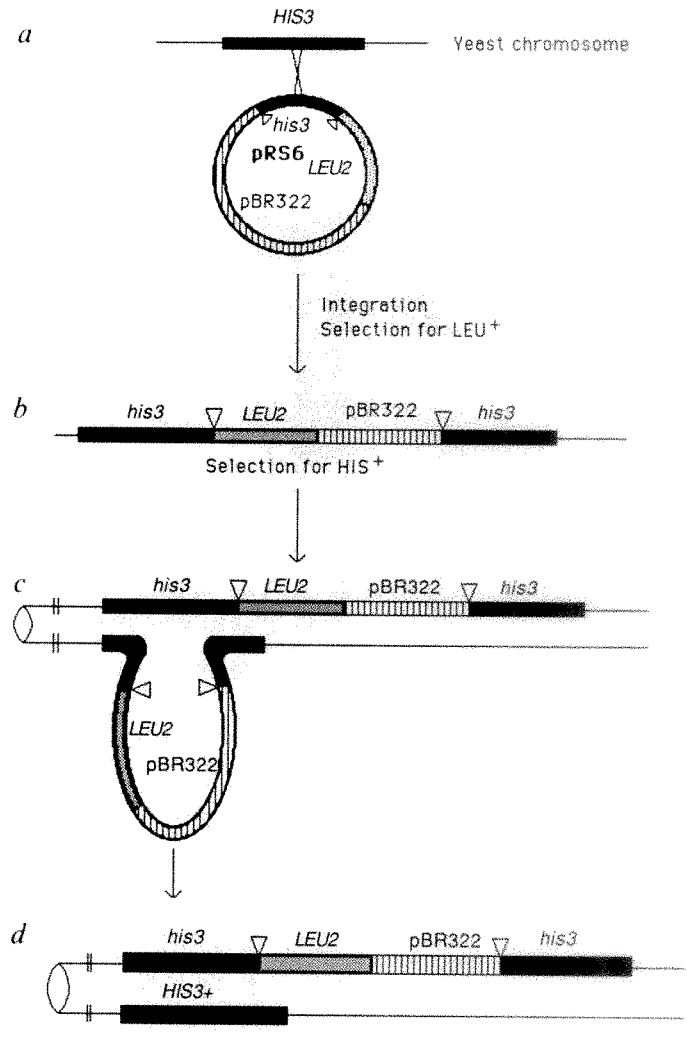

Fig. 1 Plasmid pRS6 which contains an internal fragment of the *HIS3* gene was cut within the internal *his3* fragment and integrated into the geome at the *HIS3* locus *a*. This creates a duplication of the *his3* gene in which one allele is deleted for its 3′ end and the other for its 5′ end *b*, The two alleles share about 400 base pairs of homology and thus can recombine with each other to revert to the $HIS3^+$ allele. As shown previously $HIS3^+$ recombinants do not arise by plasmid excision or by unequal sister chromatid exchange[13]. In these studies the frequency of plasmid excision was determined by putting a yeast origin of replication sequence onto the integrating plasmid. Excised plasmids could be recovered but were 100-fold less frequent than the frequency of HIS^+ formation which suggests that plasmid excision does not occur in the majority of recombinants. Reciprocal products expected to result from sister chromatid exchange were analysed by Southern blotting. The pattern characteristic for sister chromatid exchange was not found in any of 25 events examined. Thus, as a likely alternative mechanism conversion between sister chromatids (*c*) is suggested which result in deletion of the integrated plasmid on one chromatid (*d*). After segregation of the two chromatids the HIS^+ recombinant should show a HIS^+ leu^- phenotype which is found in 99% of all HIS^+ recombinants[13]. Thus, it is proposed, as a possible model, that a double strand break initiates the recombination event which is extended by an exonuclease to a gap. This gap is repaired by gene conversion from the sister chromatid as donor[13].

Table 1 Carcinogens which are detectable with the Ames assay

Carcinogen	Response in DEL (concentration range in μg ml^{-1})	Response in ICR (concentration range in μg ml^{-1})	Concentration in μg ml^{-1}	HIS$^+$ per 10^4 cells (colonies counted)	ADE$^+$ per 10^5 cells (colonies counted)
MMS[18]	Positive (1.3–260)	Positive (1.3–260)	0	0.97 (87)	0.45 (20)
			260	129 (137)	62 (654)
EMS[19]	Positive (234–2,340)	Positive (234–2,340)	0	0.97 (87)	0.45 (20)
			2,340	25.3 (1,428)	28.9 (155)
NQO[20]	Positive (0.1–2)	Positive (0.1–2)	0	0.97 (87)	0.45 (20)
			2	55.6 (562)	106 (252)
Nitrogen mustard[3]	Positive (0.1–100)	Positive (0.1–100)	0	0.79 (73)	1.3 (120)
			100	176 (84)	460 (22)
Epichlorohydrine[18]	positive (100–400)	Positive (100–400)	0	0.68 (76)	0.58 (65)
			400	48 (2,976)	50 (620)
Aflatoxin B_1[18]	Positive (2.5–50)	Positive (2.5–50)	0	0.68 (76)	0.58 (65)
			50	12.5 (277)	3.15 (70)
1-2 Dibromoethane[22]	Positive (22–4,400)	Positive (22–4,400)	0	1.2 (127)	3.3 (328)
			4,400	3.8 (31)	12.2 (10)
Dimethylhydrazine[18,23]	Positive (10–5,000)	Positive (10–5,000)	0	0.78 (75)	2.5 (245)
			5,000	3.9 (131)	4.7 (16)

The influence of MMS exposure (vol/vol) on the frequency of deletions (DEL) and interchromosomal recombination (ICR) was determined The diploid strain RS112 (MATa/α *ura3-52/ura3-52 leu2-3,112/leu2-Δ98 trp5-27/TRP5 arg4-3/ARG4 ade2-40/ade2-101 ilv1-92/ILV1 HIS3*::pRS6/*his3-Δ200 LYS2/lys2-801*) was used and contains the DEL system on one homologue (*HIS3*::pRS6) and a deletion of the entire open reading frame of *HIS3* on the other homolog (*his3-Δ200*)[27]. Single colonies were picked from YPAD medium[28] and were inoculated into 5–25 ml of synthetic complete medium lacking leucine (SC-LEU)[28] and grown for 24 hours at 30 °C under constant shaking. Cells were counted and the cell density was adjusted to 2×10^6 cells ml^{-1} in fresh SC-LEU medium. The medium containing the cells was distributed in aliquots of 5 ml each into disposable 15-ml tubes. The agent to be tested was added, the tubes sealed, and the cells were incubated for 17 hours at 30 °C under constant shaking. Cells were pelleted in a clinical table-top centrifuge. After washing the cells twice with sterile distilled water or a 10% solution of sodium thiosulphate to inactivate the agent, cells were resuspended in 0.5–1 ml of sterile distilled water, transferred to a glass tube and sonicated to disperse any clumps. Cells were counted and appropriate numbers were plated onto SC medium to determine the number of survivals, onto SC-HIS medium to score for DEL events and onto SC-ADE medium to determine the number of ICR events. The cells did not contain any clumps or tetrads. Colonies were counted after two to three days of incubation at 30 °C. Numbers of recombinants were calculated per numbers of survivors Shown is the concentration of the agent, the number of generations obtained after 17 hours of incubation, the survival and DEL as well as ICR frequencies. Data derived from less than five colonies were not included. The same control was used for MMS, EMS and NQO as well as for epichlorohydrin and aflatoxin exposure respectively. A minimum increase of twofold over the spontaneous frequency in a dose dependent manner has been regarded as evidence for inducibility. Each experiment was repeated at least three times and the results obtained were highly reproducible two plates were used for each system and each concentration. The same qualitative result was obtained with other diploid as well as haploid strains containing the DEL system. MMS and EMS were purchased from VWR Scientific and purified by vacuum distillation at 10–15 mm Hg pressure before use. NQO, nitrogen mustard, dibromoethane (ethylene dibromide), epichlorohydrine, aflatoxin and dimethylhydrazine were obtained from Sigma.

There is a large body of data establishing that animal and human carcinogens without apparent genotoxic activity exist[6]. This is the basis for the concern that there may be a considerable number of nonmutagenic carcinogens in our environment that are not detected by the conventional short term tests. As models for carcinogenesis of 'nongenotoxic carcinogens' are largely missing, a significant regulatory dilemma in their assessment of risk to humans exists[14].

There is evidence that substantial genome rearrangements are associated with cancer[8–12]. Furthermore deletions in recessive oncogenes have been implicated in carcinogenesis such as retinoblastoma[15,16]. Because of the association of genome rearrangement with cancer, a system selecting for intrachromosomal recombination which results in genome rearrangement has been constructed in the yeast *S. cerevisiae*[13] (Fig. 1). A plasmid with an internal fragment of the *HIS3* gene has been integrated at the *HIS3* locus yielding an integrative disruption of the *HIS3* gene. This resulted in two copies of the *HIS3* gene each having one terminal deletion. The most likely mechanism for reversion seems to be sister chromatid conversion between the two *his3*$^-$ alleles[13]. Because this recombination event deletes the integrated plasmid (Fig. 1) it is termed a deletion (DEL) event.

The DEL system is under different genetic control than the previously described recombination systems interchromosomal recombination (ICR) and meiotic recombination. It has been shown that mutations in the DNA repair gene *RAD1* affect the DEL recombination but have no effect on ICR or meiotic recombination[17]. This suggests that the mechanism for DEL recombination differs from that for ICR as well as meiotic recombination.

To determine whether DEL is inducible by carcinogens the diploid strain RS112 was used in which all recombination events have to occur between the two *his3*$^-$ alleles on one chromosome because the entire *HIS3* gene is deleted on the homologous chromosome. RS112 is also heteroallelic for *ade2* to measure interchromosomal recombination (ICR) between homologous chromosomes and the two recombination systems can be compared in their performance to detect carcinogens.

As mutagenic carcinogens methyl methanesulphonate (MMS)[3,18], ethyl methanesulphonate (EMS)[3,19], 4-nitroquinoline-*N*-oxide (NQO)[3,7,20], nitrogen mustard[3], epichlorohydrine[5,7,18] and aflatoxin B_1[3,18] were used (see Table 1 for procedure) and gave strong inductions with the DEL system (HIS$^+$ 20–220-fold, Table 1) as well as with the ICR system (ADE$^+$ also see ref. 21). Ethylene dibromide[22] is weakly positive with the Ames assay[3], and dimethylhydrazine[18,23] which has been reported negative[3] or weakly positive[5] with the Ames assay, both induce DEL recombination but ICR to a lesser extent (Table 1

The carcinogens formaldehyde, safrole, ethionine, urethan, auramine, methylene chloride, carbon tetrachloride, cadmium chloride and sulfate, aniline, aminotriazole, acetamide, thioacetamide, thiourea, dichlorodiphenyldichloroethylene (DDE) and ethylenethiourea are negative with all five strains currently used in the Ames assay[3,5,22], yet they have been shown to be animal or suspected human carcinogens (see Table 2 for references). All of these carcinogens induce the DEL system (2–13-fold; see Table 2).

In an international collaborative study with coded chemicals evaluating 30 different short term assays in more than 50 different laboratories[7] the carcinogens auramine, safrole, urethan

Table 2 Agents which are not detectable as 'carcinogens' in the Ames assay

Agent*	Response in DEL (concentration range in μg ml^{-1})	Response in ICR (concentration range in μg ml^{-1})	Concentrations (μg ml^{-1})	HIS$^+$ per 10^4 cells (colonies counted)	ADE$^+$ per 10^5 cells (colonies counted)
Formaldehyde[23,29]	Positive (15-70)	Positive (15-50)	0	2.3 (212)	0.49 (45)
			50	29.5 (109)	5.4 (6)
Safrole[7,18,23]	Positive (2,000-4,000)	Negative (up to 2,000)	0	1.1 (129)	0.50 (55)
			2,000	2.4 (117)	0.82 (40)
Ethionine[7,18,30]	Positive (1,000-20,000)	Negative (up to 20,000)	0	1.05 (108)	0.66 (68)
			20,000	5.4 (250)	0.80 (47)
Urethane[7,18,23]	Positive (20,000-40,000)	Negative (up to 20,000)	0	0.97 (99)	0.45 (47)
			20,000	4.8 (478)	0.40 (20)
Auramine[18,31]	Positive (1,200-1,500)	Negative (up to 1,200)	0	1.2 (127)	3.3 (328)
			1,200	2.64 (78)	1.7 (5)
Methylene chloride[22,29,31]	Positive (10,000-12,000)	Negative (up to 12,000)	0	0.95 (119)	1.1 (693)
			12,000	3.6 (109)	0.98 (5)
Carbon tetrachloride[18,23,29]	Positive (4,000-8,000)	Negative (up to 4,000)	0	1.05 (108)	0.66 (68)
			4,000	2.0 (99)	0.61 (6)
Cadmium chloride[18,31]	Positive (100-700)	Negative (up to 400)	0	0.94 (95)	0.49 (55)
			400	3.5 (145)	0.30 (8)
Cadmium sulphate[18,31]	Positive (100-700)	Negative (up to 400)	0	0.94 (95)	0.49 (55)
			200	2.6 (516)	0.2 (5)
Aniline[22]	Positive (4,000-7,000)	Positive (at 7,000)	0	1.18 (134)	1.34 (153)
			7,000	7.9 (321)	4.9 (20)
3-Aminotriazole[18]	Positive (40,000-60,000)	Negative (up to 60,000)	0	1.13 (91)	1.08 (86)
			60,000	3.1 (798)	0.7 (19)
Acetamide[18]	Positive (20,000-40,000)	Negative (up to 40,000)	0	1.13 (91)	1.08 (86)
			40,000	5.04 (782)	0.45 (7)
Thioacetamide[18]	Positive (10,000-20,000)	Negative (up to 20,000)	0	1.13 (91)	1.08 (86)
			20,000	6.28 (1,432)	1.14 (26)
Thiourea[18]	Positive (10,000-30,000)	Positive (at 30,000)	0	1.13 (91)	1.08 (86)
			30,000	25.3 (76)	20 (6)
DDE[22]	Positive (100-5,000)	Positive (at 5,000)	0	1.99 (112)	0.57 (32)
			5,000	14.1 (97)	4.3 (5)
Ethylenethiourea[7,18]	Positive (20,000-40,000)	Positive (at 40,000)	0	0.97 (85)	0.56 (49)
			40,000	3.1 (576)	1.5 (32)
Methionine	Negative (up to 40,000)	Negative (up to 40,000)	0	0.95 (119)	1.1 (693)
			40,000	0.64 (66)	0.69 (358)

The experiment was carried out as described in Table 1. The controls for the agents ethionine and carbon tetrachloride, for cadmium chloride and sulphate, for 3-aminotriazole and acetamide, and for thioacetamide and thiourea were the same. Formaldehyde, methylene chloride (dichloromethane) and carbon tetrachloride were obtained from J. T. Baker Chemical Company. Safrole, ethionine, auramine, cadmium chloride, cadmium sulfate, aniline, 3-aminotriazole, acetamide, thioacetamide, thiourea and methionine were from Sigma. Urethane, DDE (2.2-bis[4chloro-phenyl]-1,1dichloroethylene) and ethylenethiourea (2-Imidazolidinethione) were from Aldrich.

* References are given for the carcinogenicity of carcinogenic agents.

ethionine, ethylenethiourea, and 3-aminotriazole gave very poor inducibilities with all short term tests.[7]. In the collaborative study as many short term tests were positive with the amino acid methionine as were positive with the carcinogen ethionine and only very few tests could differentiate between the two compounds[7]. After incubation in up to 40 mg ml^{-1} of methionine no increase of the frequency of DEL was detectable (Table 2), whereas ethionine gave already a twofold increase at a concentration of 1 mg ml^{-1} (Table 2). Thus the DEL assay can readily differentiate between methionine and ethionine.

Formaldehyde, safrole, ethionine, urethane, 3-aminotriazole and ethylenethiourea have been shown to induce chromosome mal-segregation in fungi which may be caused by a nongenotoxic mechanism[24]. Chromosome mal-segregation associated with DEL events would show a HIS$^+$ LEU$^+$ phenotype[13]. No evidence for an increase of the frequency of HIS$^+$ LEU$^+$ colonies was found. Therefore chromosome mal-segregation does not contribute significantly to the carcinogen induced frequency of HIS$^+$ formation.

In comparing the performance of the two systems, DEL and ICR, it will be noticed that the mutagenic carcinogens induce both systems well (Table 1). The nonmutagenic carcinogens on the other hand induce the DEL system much better than the ICR system (Table 2), and the carcinogens safrole, ethionine, urethane, auramine, methylene chloride, carbon tetrachloride, cadmium sulfate and chloride, aminotriazole and acetamide would not have been detectable with the ICR system. The deletion of the integrated plasmid (see Fig. 1), which is inducible by the 'nongenotoxic carcinogens' used, indicates a genotoxic activity of these carcinogens.

In some respects DEL induction and carcinogenesis may show similar characteristics. It may be one feature of nonmutagenic carcinogens that long term continuous exposure often at toxicologically significant doses is required to induce tumours[6] which also seems to be true for DEL induction (Table 2). It also seems that nonmutagenic carcinogens may have a threshold in their dose response curve which may be missing with many mutagenic carcinogens[25]. Similarly safrole (Fig. 2*c*), carbon tetrachloride, aniline, 3-aminotriazole, acetamide, ethylene thiourea, urethane (Fig. 2*d*) and thioacetamide all show thresholds below which no response can be detected. To the contrary the mutagenic carcinogens MMS (Fig. 2*a*), EMS, NQO, nitrogen mustard (Fig. 2*b*), dibromoethane, and aflatoxin increase the frequency of DEL recombination with increasing dose over a range of at least 10- to 1,000-fold (Table 1). Another similarity between carcinogenesis and DEL recombination was revealed when cells from Bloom's syndrome patients, a disease associated with a greatly increased incidence of cancer, were shown to contain an altered, heat-labile form of DNA ligase I[26]. Similarly DEL recombination is induced about 100-fold in a yeast *cdc9* mutant temperature sensitive for DNA ligase[17].

The result of this study may give an indication about molecular events involved in carcinogenesis. DEL events may give rise to recombination between repeated elements yielding genome

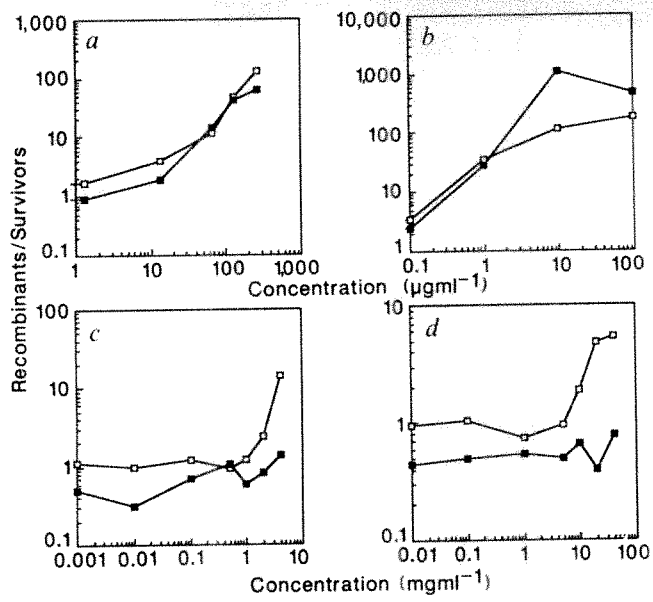

Fig. 2 Examples of dose-response curves for DEL (□, events per 10^4 survivors) as well as ICR (■, events per 10^5 survivors) recombination with two carcinogens which are detectable with the Ames assay, MMS (*a*) and nitrogen mustard (*b*) and two carcinogens which are not detectable with the Ames assay, safrole (*c*) and urethane (*d*). MMS and nitrogen mustard induce DEL as well as ICR in a dose dependent manner over a broad range of concentrations (1,000×) whereas safrole and urethane induce only DEL recombination and show a threshold, below which no induction can be detected.

rearrangements and bringing proto-oncogenes[8] into proximity with promoter or enhancer sequences. Naturally sister chromatid conversion may be important for the repair of damage induced in the S or G_2 phase and the nonmutagenic carcinogens may damage DNA specifically and only at this stage.

The DEL assay may exhibit more sensitivity to detect certain kinds of DNA damaging agents which are missed with the tests currently used. A large number of chemicals have to be tested to evaluate the DEL assay for its potential use in predictive carcinogenesis. This assay shows high reproducibility, is inexpensive, produces results within three days and requires only basic equipment and basic training in microbiology. If after further evaluation, results obtained with the DEL assay show high correlation with the carcinogenicity of the test agents, the DEL assay will be useful as a short term test for predictive carcinogenesis.

I am grateful to Professor U. Wintersberger at the Department for Tumour Biology, University of Vienna, under whose influence I developed the idea of constructing the DEL system. Dr R. D. Mehta of Prairie Biological Research Inc. is especially thanked for his help with the present work. Part of this study was carried out in the laboratory of Dr S. Prakash and was supported by Public Health Service grants from the NCI to S. Prakash. Drs R. D. Gietz, R. D. Mehta and Phil Hastings are thanked for many useful comments and for critical reading of the manuscript.

Kawasaki syndrome, an acute febrile multisystem illness of youn children, is a panvasculitis with prominent rheumatic features[1] Arthritis and pancarditis are frequent during the acute stage coronary artery aneurysms occur in 20% of cases and the diseas is now the leading cause of acquired heart disease in childhood A microbial aetiology is suggested by the acute febrile self-limite character of the disease, the regular occurrence of epidemic out breaks at intervals of 2–3 years, and the virtual restriction t young children, consistent with the early acquisition of immunit Reports of elevated DNA polymerase activity (assumed to b RNA-dependent reverse transcriptase) in cultured lymphocyte from patients with acute Kawasaki syndrome suggest that a retr virus might be the causative agent[2,3]. We have measured supe natant DNA polymerase activity in lymphocyte cultures from 4 Hawaiian patients in acute and convalescent stages of Kawasa syndrome and have been unable to demonstrate significant rever transcriptase activity or other evidence of involvement of a retr virus in the aetiology of the disease.

We established multiple cultures (two to four per patien from peripheral blood lymphocytes of 36 patients with acu Kawasaki syndrome (KS) at intervals from days two to 40 more of disease. An additional 13 patients were studied at or year or longer from onset of illness. Twenty-one KS patien

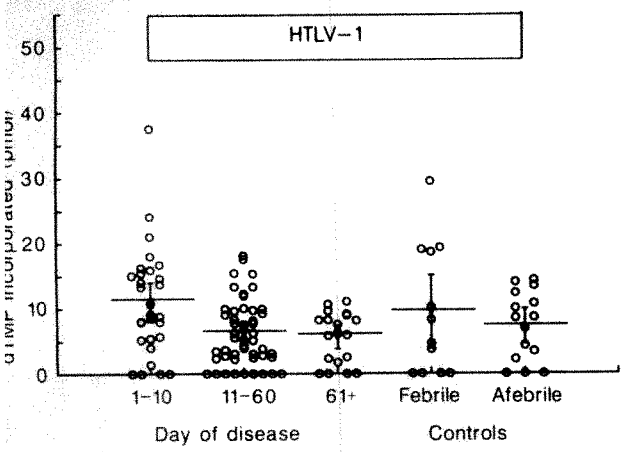

Fig. 1 Peak polymerase activity in the particulate fraction of supernatant fluids from cultures of lymphocytes collected from controls and KS patients at different stages of disease. Lymphocytes were isolated from peripheral blood of patients diagnosed as having KS by Dr Marian Melish using standard clinical criteria[6]. The mean age of the patients studied in the acute phase of disease was 29 months (range 4 to 94 months); that of control patients with febrile illness from infection with known or suspected viral or bacterial agents was 62 months (range 6 to 168 months); that of afebrile controls was 36 months (range 4 to 132 months).

Methods. Lymphocytes collected from heparinized blood by Ficoll-Hypaque sedimentation were cultured at a concentration of $1-2\times10^6$ per ml in Roswell Park Memorial Institute RPMI 1640 medium supplemented with 10% fetal bovine serum, glutamine, 2 mM final concentration, sodium bicarbonate sufficient to adjust final pH to 7.2, 100 units ml^{-1} each of penicillin and streptomycin, and phytohaemagglutinin (10 $\mu g\ ml^{-1}$). After 2–3 days incubation at 37 °C in 5% CO_2, the culture medium was decanted and replaced with complete medium supplemented with 0.5 $\mu g\ m^{-1}$ interleukin-2, 0.1% anti-human interferon-α, and 1.0 $\mu g\ ml^{-1}$ Polybrene. After 5–8 days in culture, 3×10^6 Hut-78 or Molt-4 cells or activated fresh human lymphocytes were added to each 5.0 ml culture. Culture supernatant fluids were collected at 3–5 day intervals for 21–28 days and assayed for reverse transcriptase activity. On day 21, idoxuridine 100 $\mu g\ ml^{-1}$ was added to selected cultures for 24–48 h, and then replaced with medium without idoxuridine. Supernates were collected 4–5 days later. Reverse transcriptase assays were performed[7]. Briefly, culture supernates were centrifuged in a Sorval RC-2B angle-head rotor at 2,000 r.p.m. for 10 min at 4 °C to remove intact cells and the supernatant fluid recentrifuged at 12,000 r.p.m. for 20 min to sediment cellular debris. The supernatant material was subsequently centrifuged at 25,000 r.p.m. for 90 min in an SW 28 rotor in a Beckman ultracentrifuge. In some cases, frozen (−70 °C) pre-clarified culture supernatant fluids collected on days 3–9, 10–13, or 17–28 respectively were pooled before untracentrifugation. The pellets were resuspended in 500 µl TNE buffer (10 mM Tris-HCl, 100 mM NaCl, 1 mM EDTA, *p*H 8.0), freeze-thawed twice, and a 10-µl aliquot was added to 10 µl reaction mixture containing 83 $\mu g\ ml^{-1}$ dATP, 50 mM Tris-HCl, *p*H 8.0, 5 mM dithiothreitol, 5 mM $MgCl_2$, 50 mM KCl, 0.05% Triton X-100, 0.3 mM glutathione, 0.5 mM EGTA, 50 $\mu g\ ml^{-1}$ rADT, and 25 $\mu g\ ml^{-1}$ bovine serum albumin. After 5 min on ice, 7.5 µmol [^{3}H]dTTP were added and the mixture incubated at 37 °C for 60 min with repeated shaking. Then 10 µl RNA (10 mg ml^{-1}) was added and the reaction stopped by the addition of ice-cold 0.01M sodium pyrophosphate and 10% trichloroacetic acid (TCA). The precipitate was collected on 24 mm Whatman GFA glass filters pre-soaked in 5% TCA. The filters were rinsed with chilled 0.01M sodium pyrophosphate in 1M HCl, dried, placed in scintillation cocktail (Acquasol-II, NEN), and counted in a Beckman beta scintillation spectrometer. Negative control (uninfected Hut-78 or Molt-4 cell) and positive control (HIV-1 and/or HTLV-I) culture supernates were included in all tests. Mean plus/minus 95% confidence intervals are indicated. The open bar across the top of the figure indicates 95% confidence intervals about the mean for cells infected with HTLV-I

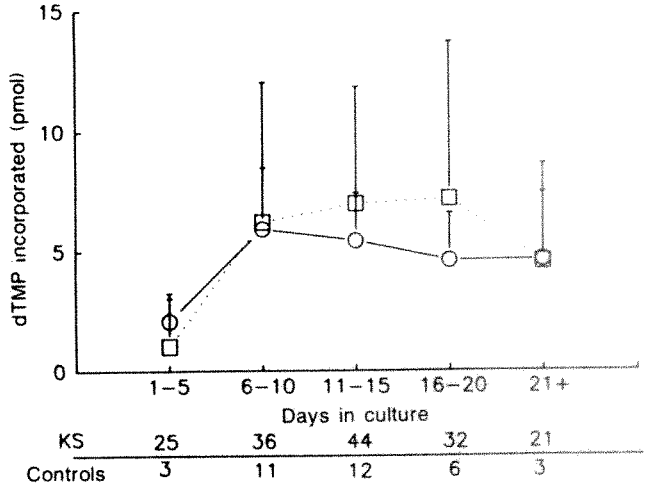

Fig. 2 Particulate polymerase activity in supernatant fluids of lymphocyte cultures. (○), KS patients in acute (febrile) phase; (□), febrile controls. The number of cultures tested at each time interval is shown on the horizontal line. Vertical brackets indicate 95% confidence intervals. Number of patients and control specimens tested at each time point is indicated below the graph.

were tested for serum antibodies to known human retroviruses—human immunodeficiency viruses types 1 and 2 (HIV-1, HIV-2) and human T-cell leukaemia viruses types I and II (HTLV-I, HTLV-II)—using the radioimmunoprecipitation assays previously described[4]. All patients except one were seronegative: one child with Japanese ancestry was seropositive for HTLV-I. DNA polymerase activity in supernatant fluid of lymphocyte culture was always low, with values significantly less than those of cell lines infected with HIV-1, HIV-2, and HTLV-I. The peak supernatant reverse transcriptase activity at every stage of the illness from the acute febrile period (from before day 10 after onset) to late convalescence (after day 30 from onset) did not differ significantly from that of febrile or afebrile child controls (Fig. 1). There was a tendency for polymerase activity in supernatant fluids from lymphocyte cultures from KS patients and febrile controls to be slightly higher after seven to 20 days in culture; but the mean was eightfold less than the mean for cells (MT-4, Hut-102) transformed by HTLV-I, a tightly cell-associated virus (Fig. 2). There was also little or no reverse transcriptase activity in cultures from afebrile convalescent patients (>10 days after onset) during any period of culture. In afebrile controls, reverse transcriptase activity was minimally elevated during the first four days of culture (Fig. 3).

In 13 cultures from 10 patients, DNA polymerase activity measured by dTMP incorporation was assayed using additional template:primers, poly(dA)·oligo(dT) and poly(rC)·oligo(dG), to determine whether the observed DNA polymerase activity was attributable to cellular DNA polymerases or to retroviral reverse transcriptase. In each case, the poly(dA)·oligo(dT) template:primer yielded values equal to those with poly(rA)·oligo(dT), suggesting that the low DNA polymerase activity was due to host cell enzymes. Furthermore, there was no activity detected with poly(rC)·oligo(dG), a template:primer preferred by RNA-dependent DNA polymerase[5]. Therefore, we were unable to demonstrate that the observed low-level DNA polymerase activity in supernatant fluids from lymphocyte cultures of KS patients was of retroviral origin.

Lymphocytes from five acute KS patients were also co-cultured with human peripheral blood lymphocytes, brain endothelial cells, and cell lines of T-lymphocytic (Hut-78, Molt-4, C8166, HPB-ALL), B-lymphocytic (Raji), and monocytic (U-937, BT4A3.5) lineage. In no case was RNA-dependent DNA

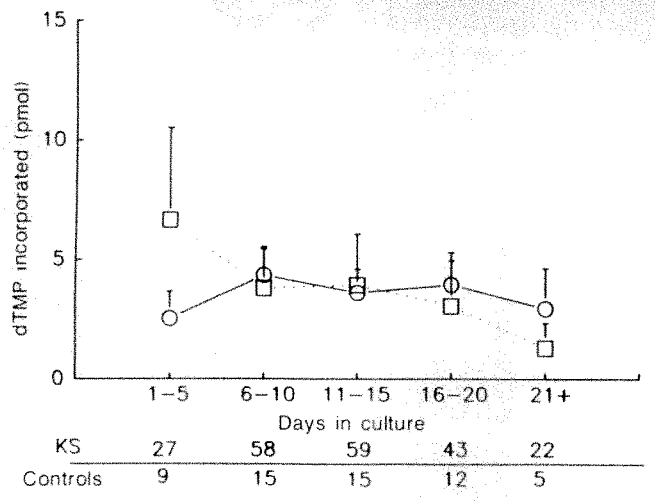

Fig. 3 Particulate polymerase activity in supernatant fluids of lymphocyte cultures. (○), KS patients in convalescent (afebrile) phase; (□), afebrile controls. The number of cultures tested at each time interval is shown on the horizontal line. Vertical brackets indicate 95% confidence intervals.

polymerase activity detected in the co-cultures. In one case however, syncytium formation was observed in a co-culture from HPB-ALL. Electron microscopic examination of this culture showed viral particles, subsequently identified as measles virus by specific immunofluorescence and radioimmunoprecipitation assays. The patient had been vaccinated with measles–mumps–rubella trivalent vaccine 8 days before onset of disease. It was concluded that the agent was measles vaccine virus.

Using standard methods for reverse transcriptase detectio we have been unable to demonstrate a retroviral aetiology f KS. The level and pattern of DNA polymerase activity detecte in KS patients in our study were similar to those previous reported[2]. In contrast to their study, cultures from our contro had values and patterns of activity similar to cultures from o KS patients. In addition, the low-level DNA polymerase activit detected in our cultures showed a template:primer preferenc consistent with cellular DNA polymerase and inconsistent wit retroviral RNA-dependent DNA polymerase. Moreover, w have been unable to detect reverse transcriptase activity i repeated co-cultures of KS patients' lymphocytes with numero human cell lines. Our experience with recovery of measles vir and its demonstration within cultured lymphocytes by electro microscopy emphasizes the danger in assuming that agen recovered from patients with KS may have a causative role.

Therefore, we believe that the aetiology of KS remair unknown. If a retrovirus is involved in the causation or th pathogenesis of this disease, techniques more sensitive than th assays presently available will be required to establish i presence.

We thank Drs Sandra Chang and Karen Yamaga for di cussion and technical advice, Faith Caplan, Donna Ching, Terr Rota and Caroline Fong for technical support. Supported i part by the Hawaii Heart Association and by the NIH.

NEW Pharmacology Titles from Macmillan

The Focus for Pharmaceutical Knowledge

Edited by **Dennis Burley, Christobel Howard and Brenda Mullinger**
This book is the edited proceedings of the 6th International Meeting of Pharmaceutical Physicians (IFAPP) held at Brighton, UK in 1987. Its 41 chapters cover a wide range of topics including current issues such as improving post-marketing surveillance, the use and abuse of phase IV trials, health care and clinical trials in developing countries.
October 1988 336 pp 234x156 mm **Expected Price £35.00** Hardback 0-333-44356-X

Peptide and Amino Acid Transport Mechanisms in the Central Nervous System

Edited by **Ljubisa Rakic, David J. Begley, Hugh Davson and Berislav V. Zlokovic**
This volume addresses itself to regulation, within the brain extracellular fluid, of peptide and amino acid levels, particularly those which are known or putative neurotransmitters and neuromodulators. Particular attention is also devoted to the way in which peptides may penetrate the blood-brain barrier or alter its permeability to other solutes.
August 1988 352 pp 234x156 mm **Expected Price £40.00** Hardback 0-333-456009

New Concepts in Depression

Edited by **M. Briley and G. Fillion**
A timely collection of results and opinions of the major preclinical and clinical researchers in the field of depression.
April 1988 392 pp 234x156 mm **£45.00** Hardback 0-333-441338

The Detection of New Adverse Drug Reactions Second Edition

M. D. B. Stephens
A practical guide to the collection, assessment and storage of adverse reactions in the development of a new drug. This revised and expanded second edition has also been updated to take into account recent research and legal developments. In addition the reference section has been greatly expanded, to over 500 references.
December 1988 352 pp 234x156 mm **Expected Price £65.00** Hardback 0-333-454170

9th IUPHAR Congress, Sydney 1987 Satellite Symposia

Pharmacology and Functional Regulation of Dopaminergic Neurons

Edited by **Philip M. Beart, Geoffrey N. Woodruff and David Jackson**
October 1988 424pp 234x156mm **Expected Price £45.00** Hardback 0-333-45944X

Peripheral Actions of Dopamine

Edited by **Christopher Bell and Barry McGrath**
December 1988 248pp 234x156mm **Expected Price 45.00** Hardback 0-333-44131-1

Serotonin

Edited by **E. Mylecharane, J. Angus, I. de la Lande and P. Humphrey**
February 1989 400pp 234x156 mm **Expected Price £45.00** Hardback 0-333-461495.

POSTDOCTORAL POSITION

in biology at M.I.T. available immediately for studies on translational control in eukaryotes with emphasis on regulation of protein chain initiation by phosphorylation-dephosphorylation mechanisms. Specific aspects focus on the roles of dsRNA-activated and heme-regulated eIF-2a kinases, and on the function of 'reversing factor' in the recycling of eIF-2. Contact: **Dr. Daniel Levin, Building E25-519, Massachusetts Institute of Technology, Cambridge, MA 02139.** Telephone: 617-253-4307. (NW3154)A

Research Associate

The Department of Clinical Neurological Sciences has a grant funded position available immediately for a Ph.D or M.D. with experience in one or more areas of cortical or cellular physiology, experimental epilepsy or behavioral neuroscience to carry out independent research.

Salary minimum: $21,000. Excellent benefits. Position SO17.

In accordance with Canadian Immigration requirements this advertisement is directed to Canadian citizens and permanent residents of Canada.

Please submit curriculum vitae, list of publications and the names of three referees by February 10, 1989:

"An Equal Opportunity Employer"

(NW3157)A

LABIMAP 2001 is one of the most exciting and potentially valuable projects current within European Molecular Biology. So it comes as no surprise that Amersham – along with the ICRF – is spearheading the UK operation, working in close collaboration with two leading French companies.

DEVELOPMENT PROJECT LEADERS

Cardiff

up to £25,000

The project's importance is such that it has gained "Eureka" status – and thus the backing of both the British and French governments. Its aim is to develop automated systems for all the major procedures used in molecular biology laboratories, making a significant contribution to, among other things, the mapping of the human genome.

Amersham will focus on the reagents element of the system: using existing and new technologies, we plan to produce first prototypes in the very near future. We are now looking for Project Leaders to head specific assignments within the Cardiff-based Development Programme, working on projects as diverse as clone-handling robotics to automated DNA extraction systems, to tight, demanding deadlines.

A broad mastery of molecular biology is clearly essential, as is a proven track record in research or development and an understanding of the contribution instrumentation and software techniques can make. More importantly, however, we are looking for people who, as well as a strong technical background, have the strong leadership qualities to motivate a team towards significant results, while continuing to make their own full practical contribution.

To attract individuals of the right calibre we can offer salaries of up to £25,000, plus full relocation expenses if required, and a wide range of benefits.

Please write, quoting ref. CR2 and enclosing full career details, to Bill Buckley, Personnel Manager, Research Products, Amersham International plc, Cardiff Laboratories, Forest Farm, Whitchurch, Cardiff CF4 7YT. Telephone Cardiff (0222) 615858.

Bringing science to life

Amersham

(8165)A

MOLECULAR VIROLOGIST

A staff position is available for a person with experience in the molecular biology of primate viruses. The successful candidate would be expected to become involved with research programs involving simian immunodeficiency disease as well as to establish his/her own area of research. Ongoing research includes studies investigating the interrelationships of opportunistic viruses with Simian Immunodeficiency Virus. The applicant would be expected to obtain research support as well as to work collaboratively with other investigators. Please send résumé, a summary of research interests, and the names of three references by Feb. 15 to: **Dr. Michael Murphey-Corb, Delta Regional Primate Research Center, Three Rivers Road, Covington, LA 70433.** (NW3159)A

CORIELL INSTITUTE FOR MEDICAL RESEARCH

Two Ph.D. staff positions available for a human geneticist, any discipline, and a molecular cytogeneticist. Appointee will develop independent research programs and provide technical and administrative support for the Human Genetic Mutant Cell Repository. Development funds and joint medical school appointments are available. Newly constructed laboratory space and technical assistance will be provided. Salary commensurate with qualifications.

Please send curriculum vitae and names of three references to: **Dr. Gerard J. McGarrity, President, Coriell Institute for Medical Research, Copewood St., Camden, NJ 08103.**

AA/EOE.

(NW3145)A

EUROPEAN SOUTHERN OBSERVATORY

The **European Southern Observatory (ESO)** is an intergovernmental organisation, responsible for astronomical research in the southern hemisphere. The eight member states of the ESO are Belgium, Denmark, France, Italy, The Netherlands, The Federal Republic of Germany, Sweden and Switzerland. The ESO occupies a leading position in the world scientific community as the first European astronomical centre. Its research is of use for a wide range of sciences as well as industry.

ESO is looking for a

EXPERIMENTAL PHYSICIST/ ASTROPHYSICIST

(ref. EPD302)

to start working as soon as possible in the High Resolution Imaging and Interferometry Project Team of the Project Division at the ESO Headquarters in Garching bei München, the Federal Republic of Germany. The major responsibility of this Division is the implementation of the Very Large Telescope (VLT), consisting of an array of four 8 metre telescopes.

Assignment:
To assume a major role in the realization of the interferometric imaging mode and adaptive optics of the VLT. To a large extent this will involve interaction and coordination with related activities in ESO member countries. Other activities may include the upgrading of the high resolution capabilities of the present ESO La Silla telescopes as well as the carrying out of a modest personal research program.

Experience and knowledge:
The candidate should have a university degree in physics, astrophysics or equivalent. Experience in the design, specification, and commissioning of sophisticated precision instrumentation. Familiarity with physical optics and precision optomechanical control systems is required. Knowledge of astronomical interferometric imaging techniques will be an asset as will be a demonstrated skill in the coordination and management of projects.

Remuneration:
The remuneration for this post is commensurate with the background, experience and family status of the candidate. The basic monthly salary (tax-free) will be between DM 4.600,– and DM 8.300,–. To this may be added a non-residence allowance of either 9% (single) or 12% (head of family) of the basic salary as well as some other allowances.

Although preference will be given to nationals of the Member States of ESO, no nationality is a priori excluded.

Applications, indicating the reference number, should be submitted **before February 28, 1989 to:**
Personnel Service,
European Southern Observatory,
Karl-Schwarzschild-straße 2,
D-8046 Garching near Munich, Federal Republic of Germany.
Tel.: (89) 320.06.216-8. (W5762)A

INSTITUTE OF PLANT SCIENCE RESEARCH CAMBRIDGE LABORATORY

Molecular Biologist

The Laboratory is seeking to appoint a Post-doctoral Fellow to join a group interested in gene expression during pollen development in maize. The person appointed will be expected to characterise one or more promoter elements which exhibit post-meiotic specificity in maize and to develop reporter gene constructs which can be transferred into tobacco. This position would be suited to someone with some experience in cell or molecular biology and with an interest in studying gene expression using the technique of 'in situ' localisation.

The position is funded by pioneer Hi-Bred International Inc. for a period of three years.

Initially the appointee will be located at the Cambridge Laboratory, but in March 1990, he or she will move to new laboratories at Norwich.

Salary will be on the Higher Scientific Officer scale £10,026-£13,460.

Applications with curriculum vitae and the names of three referees should be sent to **Mrs L Cliff, Institute of Plant Science Research, Cambridge Laboratory, Maris Lane, Trumpington, Cambridge CB2 2JB quoting reference MG/346 by 10th February 1989.**

The Institute is an Equal Opportunities Employer (8127)A

C 4-POSITION IN PETROLOGY International Distribution

GEOMAR, a Research Center for Marine Geosciences, was founded in 1987 at the Christian-Albrechts-University, Kiel Federal Republic of Germany. Within this new Institute, a position is available for a **C 4-Professor** (senior Full Professor) **in Petrology of Oceanic Crust.** Applicants are expected to have demonstrated research and teaching experience in the origin of magmatic oceanic crustal rocks. The successful applicant will be expected to carry out independent research and to participate in the teaching program within the field of marine geosciences at the Christian-Albrechts-University.

Women applicants are strongly encouraged.

Applications with supporting documents and a short summary of research perspectives should be sent before **March 30, 1989** to: **the Dean, "Mathematisch-Naturwissenschaftliche Fakultät Christian-Albrechts-Universität zu Kiel, Olshausenstraße 40 2300 Kiel 1", Federal Republic of Germany.** (W5756)A

UNIVERSITY OF BASEL
Department of Physiology Neurobiology

Applications are invited for a two year Postdoctoral position, starting August 1, 1989, to work on regulation of nicotinic acetylcholine receptor expression in skeletal muscle. Prolongation up to 4 years will be possible. Background in biochemistry of cell biology desirable. The position requires eight hours per week of teaching, in German, laboratory courses in Physiology to medical students. Salary range is sFr.50,000 to 70,000, commensurate with experience. Applications and names of two referees should be sent as soon as possible to:

Dr. H.R. Brenner,
Department of Physiology,
University of Basel,
Vesalgasse 1,
CH–4051 Basel,
Switzerland
Phone: (061) 25.40.42

(W5757)A

UNIVERSITY OF LIVERPOOL

CANCER RESEARCH CAMPAIGN
Department of Radiation Oncology

Applications are invited for the non-medical post of J.K. Douglas Lecturer (Special Appointment) in Molecular Biology.

The successful applicant will be expected to interact with a group of 4 scientists investigating the potential of anti-sense oligonucleotides to inhibit oncogene expression, which has just commenced a 5 year Cancer Research Campaign programme grant. In addition the applicant would be able to develop his/her own interests in the molecular biology of cancer cells.

Initial salary on the Lecturer A or B scale (£9,260–£19,310 per annum). Grade III technical support and some recurrent expenditure will be available during the first two years of the appointment to enable the appointee to become rapidly productive.

The Department of Radiation Oncology is situated at Clatterbridge Hospital between Chester and Liverpool in a busy oncology department. Being close to both North Wales and the Lake District it offers excellent recreational opportunities.

Informal enquiries may be made to Professor Hilmar Warenius or Dr. David Tidd (051-334 7605).

Applications, together with the names of three referees, should be received not later than 20th February, 1989, by the **Director of Staffing Services (AS), The University, P.O. Box 147, Liverpool L69 3BX** from whom further particulars may be obtained. Quote Ref. RV/231/N.

An Equal Opportunity Employer. (8103)A

THE UNIVERSITY OF WESTERN AUSTRALIA
(Perth)
LECTURER IN GEOPHYSICS
Department of Geology
(Ref. A03/89)

ed term appointment for three irs (may be extended). The ointee will be the only geo-sicist on a teaching staff of ten, l will be responsible for under-duate teaching in general and loration geophysics. The app-tee will be expected, also, to lertake personal research, and supervise honours and post-duate research projects. It is ed that the appointee will build a geophysical research group. plications are invited from sons in all areas of geophysics, it is hoped that the research erests of the appointee will vide opportunity for co-opera-n and interaction with other mbers of the Department, e.g. such fields as continental struc-e and development, or geo-sics applied to tectonics or in physical explorations. The partment has some geophysical ipment (gravity meter, seismic raction unit, X-ray scintillo-ter, long-period recording smography).

Commencing Salary: A$30,737–33,414 p.a.

Benefits include superannua-n, fares to Perth for appointees d dependent family, removal owance, study leave and long vice leave. Conditions of pointment will be specified in y offer of appointment which y be made as a result of this vertisement.

Written applications quoting erence number, telephone mber, date of birth, qualifica-ns and experience, and the mes and addresses of three erees should reach the Direc-, Personnel Services, The iversity of Western Australia, dlands 6009, Australia, by *17 bruary 1989*.

EQUAL EMPLOYMENT OPPORTUNITY IS UNIVERSITY POLICY
(W5760)A

Pharmacologist
Analgesics Research
Zambeletti Research Laboratories

Zambeletti Research Laboratories are part of Beecham Group plc, a leading research-based International Pharmaceutical Company.

We wish to recruit a research biologist for a senior position within our Analgesic project. A minimum of 5 years' research experience in CNS pharmacology, and/or electrophysiology is desirable.

The position will appeal to a scientist in late twenties or early thirties, with a record of innovative research. We need someone who is ready for the opportunity to develop new approaches to the discovery of analgesic compounds and bring them to fruition in a stimulating professional environment. Experience in the pharmaceutical industry, whilst desirable, is not essential. The work will involve liaising with scientists in other Beecham research units in the UK and Europe.

The Zambeletti Research Laboratories are situated at Baranzate, in an attractive part of Italy on the northern outskirts of Milan, near the Alps and the Lakes. A competitive salary will be offered and relocation assistance will be provided. Fluency in Italian, whilst desirable, is not essential.

Applicants should send a curriculum vitae to Dr. V. Vecchietti, Zambeletti Research Laboratories, 20021 Baranzate, Milan, Italy.

Beecham Pharmaceuticals

(8141)A

POSTDOCTORAL POSITION

Available from April 1989 to work on regulation of expression and function of the c-*mos* proto-oncogene. Applicants should have a molecular biology training and an interest in mouse embyogenesis. Send curriculum vitae and names of three referees to:— **Dr. F. Propst, Ludwig Institute for Cancer Research, St. Mary's Hospital Medical School, Norfork Place, Paddington, London W2 1PG (Telephone 01 724 5522).** (8130)A

AFRC INSTITUTE OF FOOD RESEARCH
PROTEIN CHEMIST

A protein chemist/biochemist is required to design and synthesize peptides with novel emulsification properties. The peptides will have desired functional properties in fat-water systems of both theoretical and commercial importance. Biochemical and biophysical techniques will be used to determine how they, and muscle proteins, bind and function at interfaces. A practical knowledge of protein synthesis and sequencing is essential.

Qualifications: 1st or upper 2nd class honours degree in biochemistry, biophysics or related subject with a sound background in protein chemistry. A PhD in protein chemistry, biochemistry or biophysics an advantage.

Salary: £12,445–17,032 pa.

Application forms from: The Personnel Office (Ref. 88/13) Institute of Food Research, Bristol Laboratory, Langford, Bristol BS18 7DY. Closing date 6th February 1989.

The AFRC is an equal opportunities employer. (8132)A

UNIVERSITY OF WARWICK
Research Technician
Molecular Biology

The Department of Biological Sciences has two vacancies for MRC funded Research Technicians to work within the Virology research Group. The projects involve the study of either a human adenovirus protein involved in RNA metabolism or the molecular mechanisms of pathogenesis in mammalian reoviruses.

The contract posts are available for up to three years.

Experience of recombinant DNA techniques and tissue culture would be an advantage, but interest in the project and an enthusiasm to learn new techniques are equally important. Full training will be given where necessary. Salary on the Technician Grade 3 scale: £6,636–£7,828.

Application forms from the **Personnel Office, University of Warwick, Coventry CV4 7AL (0203 523685) quoting Ref No 23/4T/88** (please mark clearly on envelope). Closing date for applications 25 January 1989.

An Equal Opportunities Employer. (8123)A

KING'S COLLEGE SCHOOL OF MEDICINE & DENTISTRY of King's College London
Post-Doctoral Research Assistant in Pharmacology

This position, suitable for a recent doctoral graduate, is to investigate the pharmacology of lymphocytes in allergic asthma. The position is available for two years and the successful candidate will be required to work with Dr. C. Page (King's College London, Chelsea Campus) in collaboration with Dr. J. Costello (Thoracic Medicine, King's College School of Medicine and Dentistry).

Salary will be on the scale £9865 – £15720 plus £1650 London Weighting Allowance per annum.

Further details are available from Dr. C.P. Page, Department of Pharmacology, King's College London, Manresa Road, London, SW3 6IX. (Telephone: 01-351 2488 ext. 2583).

Applications, including a full curriculum vitae and the names of two referees should be sent to the **Secretary of the School, Bessemer Road, London SE5 9PJ by 8th February 1989.** (8108)A

La Trobe University
Australia
School of Physical Sciences
SENIOR RESEARCH ASSISTANT IN PHYSICS

(Fixed term)

A Research Associate (Experimentalist or Theorist) is required to work on the irregular structure of the ionosphere at mid-latitudes. The appointee will be a member of the group consisting of E.C. Butcher, K.D. Cole, P.L. Dyson, E.A. Essex and P.R. Hammer. The group has a Digisonde 256, Fabry-Perot interferometer, Faraday polarimeters, Differential Doppler receivers, HF Doppler system, geomagnetic pulsation recorder and related equipment. The position will be funded by the Australian Research Council for one year initally.

Closing Date: 28 February, 1989. Ref. No.: ACA 5/753.

Salary: $A26,617 - $A28,118.

Applications (marked confidential) including reference number, names and addresses of three referees and curriculum vitae should be forwarded to the Staff Officer, La Trobe University, Bundoora, Victoria, Australia, 3083. (W5765)A

Equal Opportunity is University Policy. arm42189

SCHOOL OF PHARMACY
(UNIVERSITY OF LONDON)
TEMPORARY LECTURER IN PHARMACOLOGY

Applications are invited for the post of Temporary Lecturer in Pharmacology, tenable for two years with effect from 1 October 1989. The appointment will be at the Lecturer A grade (salary in the range £9,260-£14,500 + £1,650 London Allowance). Prospective candidates are welcome to discuss the position informally with Professor N G Bowery (01-837-7651 Extn 31).

Applications in the form of a Curriculum Vitae and naming two referees should be submitted to **Mr N J Rampley, Assistant Secretary, The School of Pharmacy, University of London, 29-39 Brunswick Square, London WC1N 1AX** by no later than the end of February 1989. (8129)A

PROFESSORSHIP IN SEDIMENTARY GEOLOGY
University of Mainz, West Germany

The Department of Geosciences, University of Mainz, invites applications for a tenured professorship in sedimentary geology (C-3 level, equivalent to senior lecturer in UK and associate professor in US) beginning April 1st, 1989.

Duties include teaching (in German) in introductory geology, in the wider fields of sedimentology, and supervision of student at MS and PhD levels. The successful candidate is expected to develop an active program of grant-funded research in the field of clastic sediments with focus on facies and basin analysis, and with special emphasis on sequence stratigraphy. Cooperation in a planned interdisciplinary research project focussed on various topics of crust-mantle evolution is expected. Applications of candidates with additional interests, e.g. in environmental geology, are particularly welcome.

A PhD is required, and preference will be given to candidates with teaching experience and an outstanding record of research in sedimentology.

Please submit full curriculum vitae, 3 references, publications and a statement of teaching and research interests to the **Dekan, Fachbereich Geowissenschaften, Universität Mainz, Postfach 3980, D-6500 Mainz, F.R.G.** Applications should be submitted by Feb. 28th, 1989.

(W5758)A

PROTEIN CHEMIST
RUAKURA AGRICULTURAL CENTRE
MAF, HAMILTON, NEW ZEALAND
VACANCY NO. MTN 88/24

The Ruakura Animal Reseach Group of the Ministry of Agriculture & Fisheries has an opening for a protein chemist. The appointee will be required to develop and extend existing programmes in animal physiology research including growth and lactation physiology, reproduction and disease control.

The successful candidate will have proven expertise in the contemporary technology of protein chemistry and have demonstrated the ability to communicate and collaborate with associates in a multi-disciplinary team. Specific skills in hybridoma ELISA and immunocytochemistry technologies and experience in growth factor biochemistry or endocrinology would be an advantage.

The minimum qualifications are an honours degree and PhD and preference will be given to applicants with post-doctoral experience.

Hamilton is a medium sized community (popn 100,000) set in farmland with excellent access to all forms of outdoor recreational activities.

Further information can be obtained from Mr Ken Jury, Manager Animal Sciences, Ruakura Agricultural Centre, Private Bag, Hamilton, New Zealand; Telephone (+64 71) 62839; Fax (+64 71) 385 658.

Applications quoting vacancy number MTN 88/24 and including a curriculum vitae and the names of two referees should be sent to:

Management Support Officer
Animal Research Group
MAFTech
Ruakura Agricultural Centre
Private Bag
Hamilton
NEW ZEALAND

Applications for vacancy close on 28 February 1989. (W5763)A

POSTDOCTORAL POSITION

in biology at M.I.T. available immediately for studies on translational control in eukaryotes with emphasis on regulation of protein chain initiation by phosphorylation-dephosphorylation mechanisms. Specific aspects focus on the roles of dsRNA-activated and heme-regulated eIF-2a kinases, and on the function of 'reversing factor' in the recycling of eIF-2. Contact: **Dr. Daniel Levin, Building E25-519, Massachusetts Institute of Technology, Cambridge, MA 02139.** Telephone: 617-253-4307. (NW3154)A

NORTH STAFFORDSHIR HEALTH AUTHORITY
SENIOR RESEARCH SCIENTIST IN RHEUMATOLOGY

Department of Post Graduat Medicine, University of Kee

£14,389–£19,895 pa

This is a new post develo between the Department of F Graduate Medicine, Universit Keele and the Staffordsh Rheumatology Centre and fun for a period of 3 years. The incu bent will head and develop labo tory research into the immu inflammatory mechanisms rheumatoid diseases and will accorded appropriate acade status according to qualificati and experience. Applications invited from scientists with prov research experience from wit any of the biological sciences.

For Job Description, furth information and arrangements visit, please apply to: Dr P Dawes, Consultant Rheumat ogist, Staffordshire Rheumatol Centre, Haywood Hospital, Hi Lane, Burslem, Stoke on Tre ST6 7AG. Tel: (0782) 835721 E 302.

Applicants should submit a f curriculum vitae, plus the nam and addresses of three referees Dr P T Dawes by 28 Februa 1989. (8117)A

UNIVERSITY OF NOTTINGHAM
Medical Research Technicians (2 posts)

Applications are invited from men and women for the above posts in the Department of Therapeutics. One project, for which experience with radioimmunoassays and/or prostaglandin compounds will be important, will investigate the effects of smoking and analgesic drugs on the gastrointestinal tract. The second project, for which experience with HPLC will be important, will investigate the effect of fatty acids on the metobolic activity of the colon.

Minimum qualifications required HNC, Higher TEC or equivalent.

Current salary scale, under review, £6,686 to £9,435 per annum for a 5 day, 37 hour working week.

These are research funded posts which will be initially offered for one year.

Apply in writing, enclosing curriculum vitae and the names of two referees to **Mr. C. R. Richmond, Department of Therapeutics, University Hospital, Queen's Medical Centre, Nottingham, NG7 2UH.** (8135)A

Senior Scientist

GLAXO GROUP RESEARCH LTD.
virology department

&

MRC COLLABORATIVE CENTRE

A Joint Venture - HIV Research

Glaxo is Britain's largest and one of the world's most successful pharmaceutical companies. Our commitment to research and development of new therapeutic agents has made us the world's second largest ethical pharmaceutical company.

The Collaborative Centre operates as a technology transfer establishment designed to provide laboratory facilities for the testing of early research ideas. It also houses MRC funded projects with highly directed commercially important objectives, such as those within the MRC AIDS Directed programme.

A unique permanent vacancy has been created for a Senior Research Scientist to work in the Virology Department of Glaxo Group Research, on secondment to the MRC Collaborative Centre, to develop techniques for the assessment of anti HIV agents, and study their mode of action. You will also supervise the work of a scientist engaged on the same project.

You will have a PhD or equivalent experience, and a proven research record in virology, or a related discipline with expertise in mammalian cell culture, and preferably experience of working with HIV.

In return, you will receive an excellent salary and guaranteed bonuses, (salary range from 15k to 21k inclusive) plus a wide range of benefits including a non-contributory pension scheme, subsidised health care and restaurant, as well as an active sports and social club.

Please send a CV or telephone for an application form to Fiona David, Personnel Officer, Glaxo Group Research Limited, Greenford Road, Greenford, Middlesex UB6 0HE (01-422 3434 ext 2934) quoting reference number G88324.

(8105)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)

SENIOR RESEARCH OFFICER (postdoctoral): cell biology/immunology

Applications are invited from postdoctoral scientists for an MRC funded position in an interdisciplinary research group studying the regulation of cellular function in asthma. The successful candidate will work within the asthma group, and be primarily responsible for investigating the effect of anti inflammatory and anti allergic drugs on both the expression of the low affinity IgE receptor (the CD23 antigen) and the transduction of the evoked signal. Applicants should have a Ph.D. in biochemistry, immunology, pharmacology or a related discipline with a research background in cell biology.

The post is funded on an MRC programme grant until May 1991.

Salary on Range 1A.

Informal enquiries to Dr R J Fuller or J MacDermot (01-740 3220).

Application forms and further particulars from **the Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0NN (tel: 01-740 3204)** quoting reference AEB2/SRO.

Closing Date: 3rd February 1989. (8109)A

RESEARCH ASSISTANT

required to participate in a research programme funded by the Medical Research Council until September 1993. The project is concerned with the analysis of genes affecting pattern formation and cell orientation in *Drosophila*. The duties of the post will include the extraction and purification of DNA from plasmid cultures, sequencing, cloning and nick transplantations using various biochemical techniques.

Salary £8675-£11680 depending on age.

Applications, to include c.v and the names of two referees, to: **Dr D. Gubb, University of Cambridge, Department of Genetics, Downing Street, Cambridge CB2 3EH. Telephone 333999.** (8111)A

UNIVERSITY OF LONDON
INSTITUTE OF PSYCHIATRY
Department of Neuroscience

POSTDOCTORAL MOLECULAR BIOLOGIST

Applications are invited for the above post to join a group studying genetic factors involved in the causation of mental illness. The post involves the study of brain gene expression in man and the development of model systems to investigate gene systems involved in psychotic states. Experience in mRNA analysis/cDNA cloning techniques is preferable but not essential.

The appointment will be for 16 months in the first instance, with salary on an appropriate point on the 1A scale in the range £9865-£14500 pa plus £1650 London Allowance.

Further information may be obtained from Dr S Whatley on 01-703-5411 ext 3263.

Applications in the form of a curriculum vitae plus the names of two referees should be sent to the **Assistant Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF quoting reference SW/N.** Closing date: 10th February 1989. (8112)A

CORIELL INSTITUTE FOR MEDICAL RESEARCH

Two Ph.D. staff positions available for a human geneticist, any discipline, and a molecular cytogeneticist. Appointee will develop independent research programs and provide technical and administrative support for the Human Genetic Mutant Cell Repository. Development funds and joint medical school appointments are available. Newly constructed laboratory space and technical assistance will be provided. Salary commensurate with qualifications.

Please send curriculum vitae and names of three references to: **Dr. Gerard J. McGarrity, President, Coriell Institute for Medical Research, Copewood St., Camden, NJ 08103.**

AA/EOE. (NW3145)A

Department of Anatomy & Developmental Biology
UNIVERSITY COLLEGE LONDON

Post-doctoral Research Assistant required for project concerned with the expression of genes involved in controlling the primary phenotypic differentiation of neurones during early neural development. Initially the project will focus on sodium pump genes, for correlation with physiological experiments showing that functional activation of the Na pump is an essential part of neural differentiation. The molecular work will complement experiments using electrophysiological, tissue culture and immunohistochemical techniques. Previous experience of molecular techniques is essential.

The appointment is supported by a grant from the Wellcome Trust and will be on the 1A range, with salary according to age and experience. Starting date by arrangement asap after Jan. 1st 1989. Applications (including c.v. and two referees) should be sent to **Professor A. Warner, Dept. of Anatomy & Developmental Biology, University College London, Gower St., London WC1E 6BT,** from whom further particulars may be obtained (Tel: 01-387-7050, Ext 3359). Closing date 3 weeks after appearance of this advertisement. *Equal Opportunities Employer.* (8115)A

UNIVERSITY OF ABERDEEN
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL POSITION

A cell biologist or biochemist is required to join a team working on the biochemistry and genetics of mammalian cell DNA repair, under the direction of Dr Andrew Collins. The project will involve the production and characterisation of mutant cell lines defective in DNA replication or repair. Candidates should have a PhD and experience in mammalian cell culture.

The position is funded by the Cancer Research Campaign, for two years, with salary in the range of £9,865 – £11,680 on the IA Scale for Research and Analogous Staff. **Application forms available from the Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX (tel 0224 273500), to whom applications (2 copies) should be returned by 10 February 1989 quoting reference number DA/046.** (8116)A

INSTITUTE OF CANCER RESEARCH
ELECTRON MICROSCOPY — TECHNICIAN

The Institute of Cancer Research has a vacancy for a technician to work in its electron microscopy laboratories based at Sutton in Surrey. The laboratory provides an ultrastructural service to the Institute covering both transmission and scanning electron microscopy, with a considerable commitment to ultrastructural immunocytochemistry. In addition, the laboratory has a strong research programme on the structure of normal and neoplastic human breast epithelium.

Previous experience in electron microscopy would be highly desirable for this post, and there will be the opportunity to gain experience in both cryo-sectioning and freeze substitution.

Salary in the range of £7881 to £10711.

Applicants are advised that smoking is prohibited in the majority of the Institute's premises.

Further information on the past may be obtained from Dr. P. Monaghan on 01 643 8901 ext. 4631.

Applications should be sent in duplicate with the names and addresses of two referees to the **Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL,** quoting reference number 1 89.T.N.62. (8131)A

THE INSTITUTE OF CANCER RESEARCH
Fulham Road, London
RESEARCH OFFICER

A Research Officer is required to join a team working on the mechanism of action of interleukin 2. The applicant must have experience in laboratory work, and preference will be given to candidates with knowledge of protein chemistry and/or mammalian cell culture. A theoretical and practical grounding in immunology is desirable.

Salary scale £7,953 to £11,162 inc. according to experience.

Applicants are advised that smoking is prohibited in the majority of the Institute's premises.

To apply, please forward a CV with the names and addresses of two referees, to the **Personnel Officer, The Institute of Cancer Research, 17A Onslow Gardens, London, SW7 3AL,** quoting ref. no. 12.88.T.NS.55. (8134)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)
DEPARTMENT OF HAEMATOLOGY
TECHNICIAN

Required for research unit within the Department of Haematology. The successful applicant will be expected to spend a proportion of his/her time working on an MRC funded project on the "Molecular Genetics of G6PD" whose principal investigators are Professor Lucio Luzzatto and Dr Philip Mason. Other duties will include looking after equipment and supplies in a busy research laboratory with numerous Fellows and trainees.

Whilst a full time person is preferred, consideration will be given to maximum part-time applicants if highly experienced. Informal visits to the laboratory from suitably qualified people will be welcome.

Application forms and further particulars may be obtained from the **Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0NN (tel: 01-740 3204)** quoting ref: AFA2. Closing Date: 9th February 1988.

Salary on range £7,415–£10,148 + £1,267 London Allowance per annum. (8146)A

UNIVERSITY OF OXFORD
University Laboratory of Physiology
POSTDOCTORAL NEUROPHYSIOLOGIST

A postdoctoral position is available, funded by the Wellcome Trust for up to 4 years, to study cortical processing of somatosensory information from the primate hand. Experience with extracellular recording techniques, animal taining and computer analysis of neurophysiological data would be an advantage. Further information may be obtained from Dr. John Phillips, University Laboratory of Physiology, Oxford 272511.

Salary (Research Assistant Grade 1A), £9,865-£15,720 p.a.

Written applications, including a CV and the names and addresses of two referees, should be sent to the **Administrator, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT.**

The University is an Equal Opportunity Employer. (8145)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE
World Health Organisation collaborating centre for Reference and Research on Viral Hepatitis
RESEARCH FELLOW IN BIOCHEMISTRY OR VIROLOGY
Department of Clinical Sciences

Applications are invited from post-doctoral scientists with experience in protein bio-chemistry to work with a small group headed by Professor A J Zuckerman on the development of novel vaccines against AIDS. Appointment for three years on salary scale 1A for Research and Analagous staff (£11,315 to £17,170 inclusive of London Weighting).

Please send curriculum vitae and names of two referees to **Peter Guildford, Personnel Officer, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT or telephone 01-636 8636 ext. 201** for an application form. Closing date 6 February 1989. (8147)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
UNIVERSITY OF LONDON
DEAN

The School is seeking a successor to Dr Bruce MacGillivray, who retires from the post of Dean in the Autumn of 1989. The new Dean must be medically qualified. He or she will direct the School's internal affairs, maintain and develop its relationship with the University, and further the existing interactions with the Regional and District Health Authorities.

Confidential enquiries, suggestions and recommendations are invited, and should be addressed to **Dr C.W.H. Havard (Chairman of the Search Committee), Royal Free Hospital School of Medicine, Rowland Hill Street, London NW3 2PF,** by 10 February 1989. (8153)A

ANIMAL ECOLOGIST ENDOWED CHAIR IN VETERINARY MEDICINE

ANIMAL ECOLOGIST is sought with experience preferably in domestic animal species and their interaction with humans for a tenure-track faculty position and endowed chair in the School of Veterinary Medicine, University of Pennsylvania. Additional background may include ethical issues, the use of animals, and insight into the ethical belief system of the veterinary profession. Candidates should have credentials of innovation and academic leadership. Address inquiries to:

Dr. K.C. Bovee, Chairman
Moore Chair Search Committee
School of Veterinary Medicine
University of Pennsylvania
3850 Spruce Street
Philadelphia, PA 19104-6010

The University of Pennsylvania is an Equal Opportunity/Affirmative Action Employer. (NW3148)A

ENDOWED PROFESSORSHIP
AT OREGON STATE UNIVERSITY
VALLEY CHAIR IN MARINE BIOLOGY

Oregon State University

The Department of Zoology at Oregon State University invites applications and nominations for the *Wayne and Gladys Valley Professorship in Marine Biology*. We expect the successful candidate to contribute substantially to research and graduates training in some aspects of marine biology. Applicants should have an established international reputation in marine biology, including a strong research program with evidence of continued growth and development. Teaching opportunities may include a graduate course in the candidate's specialty and participation in a Marine Biology course, team-taught each spring at the Hatfield Marine Science Center (HMSC) in Newport, Oregon. Research space and facilities are located on the main campus in the Department of Zoology, but we encourage research activity at the HMSC, where additional research facilities and resources are available.

Oregon State University has considerable strength in the marine sciences, including scientists in the Colleges of Science (Zoology, Botany and Plant Pathology, Biochemistry/Biophysics, Microbiology, General Science), Agriculture (Fisheries and Wildlife), and Oceanography. The Department of Zoology includes an active group of Marine Biologists with expertise in behavioural, population and community ecology, paleobiology, invertebrate zoology, ichythyology, evolutionary biology, and physiology.

Review of applications will begin February 1, 1989. Deadline for applications material is September 15, 1989. Nominations should address the relevant qualities of the nominee. Applications should include a curriculum vitae, copies of representative publications, a statement of research goals, and the names of four references sent to: **Dr. Bruce Menge, Chair, Marine Biology Search Committee, Department of Zoology, Oregon State University, Corvallis, Oregon 97731-2914.** *Oregon State University is an Equal Opportunities/Affirmative Action Employer and complies with section 504 of the Rehabilitation Act of 1973. OSU has a policy of being responsive to the needs of duel career couples.* (NW3153)A

MOLECULAR VIROLOGIST

The School of Medicine at Case Western Reserve University invites applications from new or established investigators for a program in molecular virology. We are seeking faculty members with primary interests in virology, especially in the area of human retroviruses and AIDS research. The CWRU School of Medicine provides a strong and interactive environment for collaborative research among basic and clinical investigators. Ample resources and newly renovated facilities are available for this program. Case Western Reserve University is an Affirmative Action and Equal Opportunity Employer. Interested applicants should contact:

Hsing-Jien Kung, Ph.D. and
Jerrold Ellner, M.D.,
Co-Chairmen,
Virology Search Committee,
Office of Academic Programs,
Case Western Reserve
University School of Medicine,
2119 Abington Road,
Cleveland, Ohio 44106.

(NW3041)A

HEAD, ENDOTHELIAL CELL RESEARCH

Berlex Laboratories, Inc. is a leader in basic research of endothelial cell function. We currently seek an internationally recognized scientist in endothelial cell biology to join our highly visible team to ensure progress of on-going programs, to initiate new research directions and to be part of future breakthroughs which can be applied to better understanding and novel treatment of atherosclerosis. The successful candidate will have the title of Investigator, the second highest rank in our scientific ladder.

To qualify, your background should include a Ph.D. in cell biology, biochemistry, physiology or molecular biology, at least five (5) years of post-doctoral training and an excellent publication record. Experience with endothelial cell biology is highly desirable.

Berlex Laboratories is part of a global family of companies engaged in the research, development, manufacturing and marketing of chemical-pharmaceutical products in 120 plants and subsidiaries in 140 countries, employing over 25,000 people. Combined sales are in excess of $2.7 billion.

At Berlex Laboratories, you will be supported, recognized and encouraged to pursue your scientific career and ideas. In addition to the excellent resources and stimulating research environment, the position offers an attractive salary and benefit package. For immediate, confidential consideration, send your CV and salary history to: **Lila Bernstein**, Manager, Human Resources, **BERLEX LABORATORIES, INC.**, 110 East Hanover Avenue, Cedar Knolls, NJ 07927. Equal opportunity employer M/W/H/V.

(NW3155)A

BERLEX Laboratories, Inc.

SENIOR EMBRYOLOGIST

CAMBRIDGESHIRE

Bourn Hall is a leading centre of excellence for the treatment of infertility, specialising in advanced assisted conception techniques.

A Senior Embryologist is required to work in a small team running the IVF programme. This is a key position in the embryology department with major responsibility for ensuring the quality of IVF services. The post holder will also be expected to initiate and undertake novel and innovative research in the field.

A PhD plus a minimum of three years experience in active IVF is necessary.

An excellent salary and benefits package will be offered, including BUPA, and relocation where appropriate.

If you wish to discuss this position further, please phone Dr Mike Macnamee on Cambridge 315955. To apply please send a CV to **Penelope Bucknell, Personnel Manager, Bourn Hall Clinic, Bourn, Cambridge, CB3 7TR** quoting reference SE3. (8164)A

ADVERTISEMENT

The Department of Chemistry and Biochemistry at Concordia University, Montreal

Has an opening for a tenure-track appointment at the rank of Assistant Professor in Biochemistry to commence in September, 1989. The Department has strong research interests at the interface of Chemistry and Biology in Bioinorganic, Bioorganic and Biophysical Chemistry. We are seeking an outstanding candidate with research interests in areas of Basic Biochemistry, such as; Enzymology, Metabolism or membrane Enzymes, that will compliment our existing interests. The successful applicant will have a Ph.D. and Post Doctoral experience, will be required to establish a vigorous Research Program that will attract external funding, and teach Biochemistry effectively at the Undergraduate and Graduate levels. Start-up assistance will be available from the University, while external funds are available from Quebec and federally from the Natural Sciences and Engineering Research Council of Canada. The current salary floor for Assistant Professors is $32,003.00 per year.

Concordia University is a predominantly English Institution located in downtown Montreal close to three other Research Intensive Universities. There are 29 full-time Faculty in the Department of Chemistry and Biochemistry with active Research Programs in Biochemistry, Organic, Inorganic and Physical Chemistry, Photochemistry, and Materials Science. At the present time there are 50 Graduate Students enrolled at the M.Sc. and P.hD. levels in the Department and about 15 of these are doing Research in the area of Biochemistry. The Department is housed adjacent to the Biology Department and this facilitates collaborative Research interactions between Biochemists in the two Departments.

All qualified individuals are encouraged to apply, but in accordance with Canadian Immigration requirements, this Advertisement is primarily directed to Canadian citizens and permanent residents. Applicants should supply a Curriculum Vitae, a short Resume of Research interests, a summary of start-up requirements and arrange for three letters of reference to be sent to:

Dr. P.H. Bird, Department of Chemistry and Biochemistry Concordia University, 1433 de Maisonneuve Blvd., West, Montreal, Quebec. H3G 1M8. (NW3156)A

Research Assistant/ Demonstrator

(£7,950 – £9,009 p.a.)

A Biochemist, Food Scientist or equivalent is required to work on a Food Science related project entitled "Biochemical Characterisation of Food Proteins" sponsored by the Laboratory of the Government Chemist. The research is concerned with using modern analytical techniques to identify unique biochemical characteristics of certain foods which may be used in the assessment of purity and quality.

Candidates should hold at least an Upper Second Class Honours degree in Biochemistry, Chemistry, Food Science or related subject. The person appointed will be able to register for a higher degree.

Facilites for research are excellent. Based in purpose built laboratories you will have access to the most modern equipment both at Trent and at the Laboratory of the Government Chemist.

Further details and an application form are available from the Personnel Office, Trent Polytechnic, Nottingham, Burton Street, Nottingham, NG1 4BU, Tel (0602) 418248 Ext 2148. Please quote post number S0113. Closing date 8 February 1989. (8150)A

Trent Polytechnic Nottingham

Nottinghamshire County Council

CHARING CROSS AND WESTMINSTER MEDICAL SCHOOL (University of London)

DEPARTMENT OF ANATOMY AND HISTOPATHOLOGY

Applications are invited for a research assistant's post tenable until 30th November 1990, funded by Action Research for the Crippled Child. The work involves the development of a method to treat inherited diseases of muscle using retroviral vectors to insert cloned genetic material into muscle cells of myopathic individuals. Candidates should have gained a good B.Sc. Honours degree in Cell Biology, Virology, Biochemistry, or a related subject. Some understanding of relevant DNA techniques and a working knowledge of tissue culture methods would be desirable.

Starting salary on the Research 1B scale £8,675 p.a. plus £1,650 p.a. London Allowance. Further information may be obtained from Dr. Diana Watt (01-846-7036) or Dr. T. Partridge (01-846-7149).

Applications on forms obtainable from **The Secretary, Charing Cross and Westminster Medical School, The Reynolds Building, St. Dunstan's Road, London W6 8RP,** to be submitted within three weeks of the appearance of this advertisement. (Quote Ref: 89/03). (8152)A

UNIVERSITY OF WARWICK RESEARCH TECHNICIAN

Department of Biological Sciences

There is a vacancy for a Research Technician funded by the Medical Research Council as part of a comprehensive programme of research on the Molecular Genetics of Respiratory Syncytial Virus. Research is directed towards definition of gene function, identification of determinants of virulence, analysis of antigenic variability and vaccine development. Applicants should have experience or an interest in molecular biology and/or virology.

The post is available from 1 January 1989 for 5 years 9 months on Technician Grade 3 scale: £6636–£7828 pa.

Application forms from the **Personnel Office, University of Warwick, Coventry CV4 7AL (0203 523685)** quoting Ref No 23/T/88/14 (please mark clearly on envelope). Closing date 25 January 1989.

An Equal Opportunities Employer (8142)A

UNIVERSITY OF DUNDEE

DEPARTMENT OF SURGERY

MRC TRIAL COORDINATOR

Applications are invited from science graduates for the post of Trials Coordinator for an MRC supported trial on the surgical treatment of gastric cancer. This study is a mulitcentre one and is coordinated from an office in the Department of Surgery at Ninewells Hospital under the direction of Professor A Cuschieri.

The post which is full-time carries administrative duties (data form collection from the surgeons participating in the study, randomization to the surgical treatments and preparation of reports on the progress of the study). A limited amount of travel to other hospitals involved in the study is necessary to deal with any local problems affecting recruitment. Desirable attributes for the post include computing experience, initiative and the ability to relate and communicate with people easily.

The post will be for 3 years in the first instance. Salary will be on the Other Related Staff Grade 1 salary scale (£8,675 to £13,365), depending on experience.

Further particulars can be obtained by contacting Professor A Cuschieri at Ninewells Hospital (0382 60111 ext 2174).

Applications with full cv (2 copies) and the names of 2 referees must reach the **Personnel Office, The University, Dundee, DD1 4HN** by 3 February 1989. Please quote Ref: EST/401/89/N.

(8139)A

UNIVERSITY OF EDINBURGH
DEPARTMENT OF ANATOMY
GRADUATE RESEARCH ASSOCIATE

Applications are invited for the post of Graduate Research Associate in the Department of Anatomy, University of Edinburgh. The post is for a fixed term of three years and is concerned with the surgical repair of peripheral nerves. Previous experience of light and electron microscopy would be an advantage. The post is intended for a recent graduate seeking a career as a research associate, and it is hoped that the post will commence as soon as possible. Subject to fulfilling University requirements the successful applicant would be encouraged to read for the degree of M.Phil.

Salary on University Research Grade 1B (£8,675–£9,865).

Further particulars may be obtained from the **Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS,** with whom applications by letter, including c.v. and the names and addresses of two referees should be lodged by 9th February 1989. PLEASE QUOTE REFERENCE NO. 5625. (8107)A

RESEARCH ASSISTANT
MOLECULAR BIOLOGY

Pfizer has an exciting array of newly discovered agents for the treatment of animal diseases and for improving the health and productivity of farm livestock.

In order to maintain the momentum and productivity of our research programme we are now seeking to recruit a graduate with research experience in Molecular Biology to join one of our multi-disciplinary research teams investigating new approaches to the control of parasites in domestic livestock.

If you are a graduate in a biological discipline with up to five years research experience using cell or molecular biology techniques we would like to hear from you.

You will be responsible for experimental work aimed at developing new in vitro screens for antiparasitic agents and for contributing to basic discovery research.

This is a particularly exciting time to join Pfizer as we have a major multi-million pound expansion of our research facilities under construction demonstrating our long-term commitment to research here at Sandwich and enabling our scientists to look forward with confidence to the 1990's and beyond.

If you join us, you will be paid a good salary, be eligible for an annual performance bonus of up to 20% of salary, participate in our excellent employment benefit package of pension, share investment and private medical insurance schemes and be able to live in one of East Kent's charming towns or villages. Naturally, we will pay your removal expenses.

If you are interested send a brief c.v. to Mr D O'Callaghan, Pfizer Central Research, Ramsgate Road, Sandwich, Kent CT13 9NJ. We will take it from there.

NEURON IMAGING IN SLICES AND GANGLIA

at Howard Hughes Medical Institute, Department of Neurobiology, SUNY Stony Brook. Research Associate/ Research Assistant Professor positions for electrophysiologists interested in ion channels, confocal microscopy, calcium imaging, and synaptic function. Send curriculum vitae and three references to:

Dr. Paul Adams, Department of Neurobiology, Stony Brook, N.Y. 11794.

(NW3152)A

HERIOT-WATT UNIVERSITY & THE CAMBRIDGE IRC
RESEARCH IN HIGH TEMPERATURE SUPERCONDUCTORS

Applications are invited for a postdoctoral position of two years duration to work on the synthesis, structural characterisation by neutron and X-ray diffraction, and electrical measurements on new mixed valence cuprates of relevance to high temperature superconductors.

The successful applicant will join a collaborative programme between Dr Bruce and Professor Harper at Heriot-Watt and Dr Edwards at the Cambridge IRC. Experience in solid state chemistry or crystallography is not essential. Salary will be on the normal RA 1A scale £9867-£15720 with USS.

Please send CV and the names of two referees to **The Staff Office, Heriot-Watt University, Riccarton, Edinburgh EH14 4AS** quoting ref no 2/89/N as soon as possible. Preliminary enquiries and further details may be obtained from Dr P G Bruce, tel: 031-451 3107. (8120)A

DISCOVERY BIOLOGY ANIMAL HEALTH

Section Head — to £30,000 + car

Our Client is one of the world's largest animal health businesses with a broad line of products primarily for the cattle, swine and poultry sectors. Their continued success can be attributed to the Company's commitment to original research which results in an enviable succession of novel and commercially viable agents to improve the productivity and health of farm livestock.

An unusual opportunity has now arisen for a talented research scientist to join the UK Animal Health Group to lead a well established team of scientists engaged in discovery biology, primarily concerned with parasitology, but including exploratory projects in other fields.

Ideal candidates will have a good first degree in a biological discipline followed by a PhD, preferably in Parasitology. Clearly there must be a proven record of scientific achievement and it would be a distinct advantage if some of the experience had been gained in industry orientated towards animal health.

Salary is certainly not likely to prove an obstacle and there is an excellent benefits programme which includes a car and relocation expenses.

This is an equal opportunity appointment and those interested in receiving further details should contact Roger Bryant or Martin Duchesne at:

Search And Selection Limited
Management Consultants
Suite 3, Highway House, 17 London End,
Beaconsfield, Bucks HP9 2HN Tel: 0494-671651 (8126)A

NATIONAL INSTITUTE OF
BIOLOGICAL STANDARDS AND CONTROL

HEAD OF BIOLOGICAL SERVICES

Applications are invited from senior scientists for the position of Head of the Institutes Biological Services Section.

The Institute is responsible for the standardization and control of biological substances used in human medicine and is a major WHO international laboratory for Biological Standards.

The section is responsible for the husbandry of a wide range of laboratory animals. As well as having managerial control of the section the successful candidate will be expected to participate in a mutually agreed field of biological research relevant to the Institutes responsibilities.

Applicants should be appropriately qualified scientists in Veterinary Science or a Biological Science, preferably with substantive management experience, gained in a similar environment.

Salary depending on qualifications and experience will be up to £26,125 per annum inclusive of London Weighting allowance.

Informal enquiries can be made to Ms M. Kelly. Details of the post and the Institute are available from the Personnel Office.

To apply, please submit a full c.v. together with the names and addresses of three referees to The Personnel Office, National Institute for Biological Standards and Control, Blanche Lane, South Mimms, Herts. EN6 3QG.
Telephone No: 0707 54753 Ext 457.

National Institute for Biological Standards and Control

2 POSTDOCTORAL POSITIONS IN MOLECULAR CELL BIOLOGY

Two positions are available immediately to study the molecular mechanisms of cell and tissue interactions which regulate cell differentiation in the embryonic visual system. Emphases are on the role of plasma membrane molecules and molecular genetics. Salary commensurate with experience.

Send C.V. and three letters of recommendation to:

Dr. Paul J. Linser
Whitney Laboratory
University of Florida
9505 Ocean Shore Blvd.
St. Augustine, FL 32086

An affirmative action equal opportunity employer. (NW3146)A

POST DOCTORAL POSITION

Available to work on molecular biology of plant defense reactions. The post is for one year in a first instance to start no later than May 1st.

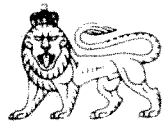
Send C.V. and two references to:

Dr. P. RICCI
STATION DE BOTANIQUE ET PATHOLOGIE VEGETALE
Villa Thuret — 65 Bd. du Cap
Chemin Raymond
06600 ANTIBES
Tél. 93.67.88.65 (W5770)A

POSTDOCTORAL RESEARCH FELLOW

BIOMOLECULAR MODELLING LABORATORY

Applications are invited for a three year postdoctoral research fellow to work on the development of sensitive methods of detecting protein sequence homology. A database scanning algorithm will be developed both for the VAX mainframe computer and for supercomputers. There will also be opportunities to use interactive molecular graphics to predict the three-dimensional structure of proteins relevant to cancer.



The appointee must be familiar with computer programming and knowledge of protein sequences is desirable. Initial salary will be in the range of £14,000 to £16,000 depending on age and experience.

For further details contact Dr Mike Sternberg on 01-242 0200 ext 2565. Applications, including curriculum vitae and details of three referees, should be sent to Mrs P Harwood, Recruitment Officer, Imperial Cancer Research Fund, 44 Lincolns Inn Fields, London WC2A 3PX, quoting ref 55/R.

(8158)A

KING'S COLLEGE LONDON

PROTEIN CHEMIST and MOLECULAR GENETICIST

Applications are invited for two post-doctoral Research Associate appointments, one for three years and the other for one year in the first instance, in Prof H J Gould's group to study the "Receptor Binding Sites on Human Immunoglobulin E", continuing work described in Nature *331*, 180–183, 1988. The protein chemist should have experience of protein purification and binding studies, and an interest in protein engineering. The molecular geneticist should have experience in site-directed mutagenesis.

Inclusive annual salary according to age and experience on a scale £11,315–£17,170.

Further information from Professor Gould on 01–836 8851. Applications with the names of two referees, should be addressed to **Mr D M Drummie, Department of Biophysics, King's College, 26–29 Drury Lane, London WC2B 5RL.** (8155)A

MEDICAL RESEARCH COUNCIL
CYCLOTRON UNIT, HAMMERSMITH HOSPITAL

requires a RESEARCH OFFICER

within the Biology Group of the Clinical Studies section. The work of the group is linked closely with the Unit's clinical programme of Positron Emission Tomography in man and includes the experimental use of tracer radioisotopes to follow dynamic processes of metabolism and neurotransmission in brain and heart. Some experience in pharmacology and/or physiology would be an advantage.

Salary in the range £8,821–£14,055 (pay award pending) depending on age, qualifications and experience.

For application forms and further details please contact:
Miss Jacky Wood, Personnel Officer, MRC Cyclotron Unit, Hammersmith Hospital, Du Cane Road, London W12 0HS. Telephone: 01–740 3162.

Closing date: 2 weeks.

The Medical Research Council is an Equal Opportunity Employer.

(8154)A

NEW ZEALAND
MOLECULAR BIOLOGISTS
DSIR

The Department of Scientific and Industrial Research has an active research programme in plant molecular genetics, applied specifically at present to the improvement of white clover, ryegrass, grain legumes, vegetables and fruit. Research is also carried out in animal gene mapping, leading to transgenic animal development.

A new policy package provided by Government enables expansion of the current research programme. As a result additional scientist and post-doctoral positions have been created in the Biological Industries Group of seven Divisions of DSIR, based at Auckland, Palmerston North and Christchurch.

Applications and enquiries are invited for the following positions:

Scientist, Plant Molecular Biology:
An experienced molecular biologist is sought to direct a research programme into transformation techniques for apple.
(Division of Horticulture and Processing, Auckland).

Scientist, Plant Molecular Biology:
A scientist is needed to investigate transformation, gene isolation and cloning techniques for trees and ornamental crops.
(Plant Physiology Division, Palmerston North).

Scientist, Plant Molecular Biology:
A scientist is required to join a research project in plant insect resistance.
(Plant Physiology Division, Palmerston North).

Scientist, Plant Molecular Biology:
A scientist is required to work on the use of micro-projectile bombardment to introduce genes into pasture plants.
(Grasslands Division, Palmerston North).

Postdoctoral, Plant Molecular Biology:
A postdoctoral scientist is required to join a team working on cloning bacterial genes encoding anti-fungal proteins for transformation into plants.
(Crop Research Division, Christchurch)

Postdoctorals, Plant Molecular Biology:
Two postdoctoral positions are available to work on insect resistance and viral coat protein genes and introduction of these genes into forage legumes.
(Grasslands Division, Palmerston North).

Scientists, Animal Molecular Biology:
Two positions are available to work with an established gene mapping team on animal traits of economic importance.
(Biotechnology Division, Palmerston North).

Scientist, Animal Molecular Biology:
A scientist is sought to work on ruminant embryology, gene transfer into animals monitoring of transgenic offspring.
(Biotechnology Division, Palmerston North).

Scientist, Molecular Biology:
An immunologist is required to work on the production of monoclonal antibodies for the development of immunoassay kits and scale up of monoclonal antibody production.
(Biotechnology Division, Palmerston North).

Scientist, Molecular Biology:
A scientist is required to study the molecular genetics of fruit rotting fungus *Colletotrichum*.
(Plant Diseases Division, Auckland).

Postdoctoral, Molecular Biology:
A microbial geneticist is needed to characterise bacterial regulatory genes with a view to developing novel biosensor system.
(Grasslands Division, Palmerston North).

Scientists, Molecular Biology
Two positions are available for work on gemini viruses, cassava latent virus and chloris-striate mosaic virus to develop these as high copy expression vectors.
(Plant Diseases Division, Auckland).

Scientists, Molecular Biology:
Three scientists are required to work on RNA viruses with a view to developing resistant white clover, peas and lentils.
(Plant Diseases Division, Auckland).

Conditions of employment to these positions are negotiable and may be short term or permanent. Salaries commensurate with qualifications and experience.

Enquiries about the advertised position should be directed to:

Ana Pickering
Resource Development Scientist
DSIR
P.O. Box 1578
Wellington

University of Strathclyde

DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

LECTURESHIP IN MOLECULAR PHARMACOLOGY

Applications are invited from candidates with a higher degree in pharmacology, biochemistry or a related discipline for a Lectureship in Molecular Pharmacology. In addition to teaching, the successful applicant will be expected to conduct independent research in molecular pharmacology in the field of pulmonary disease/smooth muscle, within the Cardiovascular and Mediators Research Group. Established expertise in molecular/biomedical pharmacology techniques is essential. Salary: £9,260-£19,310 per annum. USS benefits. Application forms and further particulars (4/89) are available from **Staff Office, University of Strathclyde, Glasgow G1 1XQ.** Closing Date for Applications:– 28 February 1989. (8122)A

AFRC INSTITUTE OF PLANT SCIENCE RESEARCH
NITROGEN FIXATION LABORATORY, UNIVERSITY OF SUSSEX, BRIGHTON BN1 9RQ

BIOCHEMIST

A biochemist is required to join a team studying the nature and function of the metal clusters in nitrogenases. The appointment will be for two years in the first instance and is available immediately. The appointee will work directly with Prof. B.E. Smith, Head of the Laboratory, collaborating with other members of the team and possible outside groups as necessary.

The work will involve anaerobic handling techniques and protein isolation and characterisation. Experience in these areas and in either the application of spectroscopic techniques to the study of metalloproteins or site-directed mutagenesis techniques would be an advantage. Candidates should normally have a first or upper second class honours degree in Biochemistry or related subject with at least 2 years' post-graduate experience. Salary scale £10,026-£13,460, non-contributory pension. Send CV to **Mrs J. A. Durrant at the above address.** *The Agricultural & Food Research Council is an Equal Opportunities Employer.* (8121)A

BIRBECK COLLEGE
University of London
DEPARTMENT OF CRYSTALLOGRAPHY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a postdoctoral research assistantship funded by the Muscular Dystrophy Group. The project involves the expression, purification and crystallization of domains of dystrophin, the protein product of the DMD gene, with a view to a full three dimensional structure determination. Experience in protein biochemistry and structural studies would be an advantage. Salary will be within range £11515 – £13800 p.a. depending on age and experience. Post tenable for up to three years.

Applications in duplicate including a full curriculum vitae and names and addresses of two referees should be sent to the **Assistant Secretary (Personnel), Birbeck College, Malet Street, London, WC1E 7HX by 3rd February 1989.**

Further details can be obtained from Dr. J.M. Goodfellow or Professor T.L. Blundell on 01-631 6368. (8137)A

RESEARCH FELLOW IN ENDOCRINOLOGY

DIVISION OF NUTRITION AND ENDOCRINOLOGY

A Postdoctoral Position is available to study the interactions of dietary lipids and hormones in human breast cancer, and investigate the effects of antiestrogens on the synthesis of specific hepatic proteins.

Experience in endocrine assay techniques and/or steroid biochemistry is required.

This appointment is well suited to an individual seeking either a career in clinical laboratory endocrinology or basic endocrine research. Modern, well-equipped research facility located in northern suburb of NYC. Please submit CV to:

Dr. David P. Rose, Division Chief
Division of Nutrition & Endocrinology
AMERICAN HEALTH FOUNDATION
1 Dana Road, Valhalla, NY 10595.

An equal opportunity employer. (NW3149)A

UNIVERSITY OF SURREY
DEPARTMENT OF BIOCHEMISTRY
Research Officer
The Role of Salivary Proteins in Sensory Astringency

Applications are invited for a post of Research Officer, funded by MAFF, CFDRA and a consortium of industrial sponsors, for three years and available immediately. Applicants should have a good degree in Biochemistry, chemistry or an appropriate applied science, and be willing to apply this expertise to a challenging project investigating the role of salivary proteins in sensory astringency. Practical experience of protein separation (HPLC, electrophoresis), ligand binding (dialysis spectroscopy) or immunoassays would be an advantage. The successful applicant will join the Clinical Biochemistry and Nutrition Research Group. Direct supervision will be by Dr M N Clifford (0483 571281 ext 2506), leader of the Nutrition and Food Chemistry Research Team, and there will be regular meetings with staff of CFDRA and industrial sponsors.

Salary will be on the Research and Analogous 1B scale (£8675 — £10460 pa) depending on age, qualifications and experience.

Applications in the form of a curriculum vitae (3 copies) including names and addresses of two referees should be sent to the **Personnel Office (JLG), University of Surrey, Guildford GU2 5HX, quoting reference 799N by 3 February 1989.** (8133)A

University of Edinburgh
DEVELOPMENTAL MOLECULAR BIOLOGIST

Applications are invited for the position of research associate (RA1B scale) to study the role of homeobox genes in the development of the leech. The post is funded by the SERC for a period of 3 years. Recent graduates or students expecting to graduate this year with a good honours degree are encouraged to apply. Experience with recombinant DNA methods is desirable; a prior knowledge of invertebrate development would be useful but not essential. The successful applicant will be based in Edinburgh (D. Price, Psysiology) and will collaborate with Dr. S. Blackshaw at Glasgow University (Cell Biology) and with Dr. D. Weisblat's group at U. C. Berkeley, California. There may be an opportunity to register for a PhD. Salary from £8,675 to £9,865.

Further particulars can be obtained from the Personnel Office; informal enquiries to D. Price are encouraged (031-667-1011 ext. 2357).

Applications including a c.v. and names of two academic referees should be sent to **The Personnel Office, 63 South Bridge, Edinburgh EH1 1LS** by the 28th February.

— the professionals' choice

SYNTHETIC ORGANIC CHEMISTRY

GRADUATE INTO THE WORLD'S NUMBER ONE PHARMACEUTICAL COMPANY

MSD is the world's number one pharmaceutical company. Our policy is to recruit the best scientists available to participate in the discovery of new drugs. We have a number of vacancies for experienced or newly qualified graduates to work on the synthesis of biologically active molecules for the treatment of diseases of the central nervous system. This specialist area calls for talented individuals who can blend academic ability with our pioneering approach. A good grounding in organic chemistry is essential.

Successful applicants will benefit from exceptional facilities at our extensive research centre and the opportunity to work with people renowned worldwide. Those who join us will find real potential to progress their future in research and will participate fully in all aspects of the scientific projects at the centre, which include contributing to published articles. Attendance at external seminars and conferences is positively encouraged.

Salaries are extremely competitive and benefits include: private health care, pension scheme, free life assurance, an active sports and social club and initial housing assistance. An added bonus is our beautiful rural location on the Herts/Essex border, close to major road and rail links and 30 miles from central London.

Please write with full curriculum vitae and salary details where appropriate to Cathy Woodbine, Personnel Manager, Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex, CM20 2QR.

MERCK SHARP DOHME

POPULATION BIOLOGISTS

The Program in Ecology, Evolution, and Behavior of the Department of Biology at Princeton University plans to appoint two population biologists to begin in September 1989, one a tenure-track Assistant Professor, the other at an open rank. Preference will be given to candidates with a strong research program involving field work or theory in ecology and evolutionary biology. The current faculty of Princeton's Graduate Program in Ecology, Evolution, and Behavior are: John Bonner, Jim Gould, Peter Grant, Henry Horn, Steve Hubbell, Marty Kreitman, Bob Lisk, Naomi Pierce, Dan Rubenstein, and Ted Sullivan. The closing date for applications is March 3, 1989. Applicants should send a curriculum vitae and arrange for three letters of reference to be sent to **Dan Rubenstein, Search Committee, Program in Ecology, Evolution, and Behavior, Guyot Hall, Princeton University, Princeton, NJ, 08544-1003.**

Princeton University is an Equal Opportunity/Affirmative Action Employer. (NW3092)A

TRUDEAU INSTITUTE, INC.

POSTDOCTORAL ASSOCIATE TO STUDY T CELL-MEDIATED IMMUNITY

A vacancy exists for a postdoctoral fellow interested in studying immunity to tumor and histocompatibility antigens. Current studies deal with various aspects of T cell-mediated rejection of tumors and allografts. The opportunity to study T cell-mediated immunity to bacterial infection also exists. Applicants should have basic training in immunobiology. Starting salary will be commensurate with experience and includes liberal fringe benefits. Subsidized institute housing is available.

The Trudeau Institute is a private, not-for-profit, basic medical research institution located on the shore of Saranac Lake and near Lake Placid, N.Y.

Send curriculum vitae and names of three references to:
Dr. Robert J. North, Director Trudeau Institute, Inc., P.O. Box 59, Saranac Lake, NY 12983. (NW3080)A

GROUP LEADER POSITION IN MOLECULAR NEUROBIOLOGY

Friedrich Miescher-Institut Basel, Switzerland

The Friedrich Miescher-Institut, a foundation devoted to basic research in cell biology, invites applications for an independent group leader position in neurobiology. Candidates are sought who have an interest in using molecular biology techniques to study the differentiation and the regeneration of the neuronal cell in vitro and in vivo. The candidate should have at least three years postdoctoral experience in molecular aspects of cellular neurobiology. The appointee's group will join two other groups working in the field of neuronal development, led by Dr. Andrew Matus (cytoskeleton) and Dr. Denis Monard (growth factors).

The Institute has strong research programs in cellular and molecular biology and offers an outstanding scientific environment with excellent research facilities. Employment conditions for the offered position are highly competitive. The envisaged starting date is mid-1989 or later. Applications, including an outline of the candidate's proposed research project, should be submitted by February 28, 1989 to **Dr. Denis Monard, Friedrich Miescher-Institut, P.O. Box 2543, CH-4002 BASEL, Switzerland.**

(W5748)A

EXPERIENCED CRYSTAL GROWER

A experienced crystal grower (Senior Research Associate) is needed to join an existing group in the Institute for Materials Research (IMR) at McMaster University concentrating initially on the development of techniques for the growth of single crystals of *high temperature oxide superconductors*. The IMR has for many years maintained extensive facilities for preparation, crystal growth and characterization of advanced materials, supported by a technical staff, including a crystal grower, who interact with a number of chemistry, physics and materials science faculty. It is proposed to expand the existing crystal growth capability of the IMR by the addition of one senior crystal grower, together with appropriate equipment and technical support. Ideally, candidates will have a PhD in a relevant discipline such as solid state chemistry: solid state physics or materials science with a minimum of three years experience beyond the PhD or a Master's or Bachelor's degree with eight or more years of experience. Previous experience with a range of crystal growth methods is highly desirable. Salary will be commensurate with the qualifications and experience of the successful candidate.

Applications including a C.V. and a list of at least three professional references should be sent before March 31, 1989 to:

Dr. A. John Berlinsky, Director
Institute for Materials Research
McMaster University
1280 Main Street West
Hamilton Ontario
L8S 4M1

(NW3034)A

Director, Genetic Diagnostic Laboratory:

A position available immediately for a Ph.D. with experience in molecular biology/biochemical genetics to direct a genetic diagnostic laboratory. There is ample opportunity for independent research and faculty appointment at Duke University Medical Center (rank dependent on experience). The candidate will join an established and growing, comprehensive academic genetic and metabolic program with expertise in clinical genetics, molecular and biochemical genetics associated with a major mass spectrometry facility. Duke University is an Equal Opportunity/ Affirmative Action Employer. Send curriculum vitae and three references to:

Y.T. Chen, M.D., Ph.D.
Associate Professor of Pediatrics
Division of Genetics and Metabolism
Department of Pediatrics
P.O. Box 3028
Duke University Medical Center
Durham, North Carolina 27710 (NW3161)A

ASSISTANT OR ASSOCIATE PROFESSOR OF PHYSICAL SCIENCES EDUCATION

Teach courses in one of the departments of the Physical Sciences area, engage in scholarly activities, and assist with development and implementation of a program in Physical Sciences Education. Appointment at rank appropriate to qualifications ($27,588 to $48,204). Applicant must have Ph.D. degree in one of classical physical sciences areas, broad background in the physical sciences and demonstrated emphasis in science education as a primary interest. Applicants are to submit letter of application and curriculum vitae to: **Dr. James D. Crum, Dean, School of Natural Sciences, California State University, San Bernardino, CA 92407**. Applications will be accepted until position filled: will not close prior to 1 February 1989. *An Equal Opportunity, Affirmative Action Section 504, Title IX Employer.* (NW3164)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF VETERINARY PATHOLOGY

RESEARCH ASSOCIATE: POSTGRADUATE/ POSTDOCTORAL

Applications are invited for a 1 year appointment funded by the Agricultural and Food Research Council, with a possible extension, pending grant renewal, for a further 5 years to work in fundamental aspects of the sheep immune system. Candidates should have a Ph.D. or a First Degree in immunology and some research experience, preferably including molecular biology techniques. The work will include characterising sheep IL-2 and the IL-2 receptor with monoclonal antibodies and heterologous cDNA probes. The reagents developed will be used to investigate the immune response in sheep with persistent viral infections. Appointees at postdoctoral level will be paid on the 1A scale, or at postgraduate level on the 1B scale with placement according to age, qualifications and experience.

Informal enquiries may be made to Dr R. Bujdoso, Department of Veterinary Pathology, University of Edinburgh, Summerhall, Edinburgh EH9 1QH. Telephone 031 667 1011 ext 5245.

Further particulars of this post are available from the **Personnel Office, 63 South Bridge, Edinburgh EH1 1LS**, with whom applications by letter including c.v. and the names and addresses of two referees, should be lodged not later than 9th February 1989. *Please quote reference No. 5624.*

VIROLOGIST

The Department of Microbiology, North Carolina State University, has available a research and teaching position as Assistant Professor in Virology. A Ph.D. degree with emphasis in plant, bacterial, or animal virology and relevant postdoctoral experience are required. The position is a 12-month tenure-track appointment and includes continuing institutional research support. The successful candidate is expected to teach, direct graduate students and develop a vigorous research program in a basic aspect of virology. Excellent opportunities exist for collaboration with other virologists on campus and in the Research Triangle Area.

Applications are invited from qualified individuals with expertise in virology. Included in the application should be a statement of research interest, curriculum vitae and list of publications. In addition, provide the names, addresses, and telephone numbers of three individuals who may be contacted for a reference by the search committee. Indicate your professional association with each referee. Application materials should be sent to:

Dr. Thoyd Melton, Virology Search Committee, Department of Microbiology, Box 7615, North Carolina State University, Raleigh, NC 27695–7615.

The closing date for applications is February 28, 1989 or until a suitable candidate is selected. Proper documentation of identify and employability will be required before the hiring process can be finalized. *North Carolina State University is an equal opportunity employer.* ((NW2975)A

FACULTY POSITION

HIV VIROLOGIST/MOLECULAR BIOLOGIST
ST. JUDE CHILDREN'S RESEARCH HOSPITAL

The Department of Virology and Molecular Biology at St. Jude Children's Research Hospital has a position available at the junior or senior level for an individual with research interests in the molecular biology and pathogenesis of human immunodeficiency virus (HIV). Candidates should have a Ph.D., M.D., or veterinary degree with research accomplishments that reflect an ability to maintain an independent program. We are seeking to complement our clinical program on AIDS and add to our current research programs which include studies of the replication and pathogenesis of influenza and paramyxoviruses, iridorviruses, adenoviruses and EBV.

The 17-member Department of Virology and Molecular Biology is part of St. Jude's multidisciplinary staff of 120 faculty and 60 postdoctoral fellows engaged in both clinical and basic research. The positions, which are well supported by institutional resources, offer opportunities for collaborative research with members of the Immunology, Tumour Cell Biology, Biochemistry, and Pharmacology Departments, as well as with members of the clinical staff.

The Institution has Core facilities for the synthesis of oligonucleotides and peptides, for peptide and DNA sequencing, a hybriodoma facility, an electron microscope facility, two shared flow cytometers, a molecular modeling/molecular biology computer facility, and a state-of-the-art animal resource center. A new basic research building will provide over 200,000 square feet of laboratory space.

Candidates should send a *curriculum vitae,* including a brief research prospectus, and names of three references to:

Dr. Robert G. Webster, Chairman,
Search Committee, Department of Virology and Molecular Biology,
St. Jude Children's Research Hospital, P.O. Box 318, Memphis, TN 38101–0318.

California State University
San Bernardino

CHAIR
Department of Biology

Responsibilities: The chair will be expected to provide leadership, encourage excellence and high standards in both teaching and research, facilitate interactions among departmental faculty and with other disciplines, develop and execute a long-range plan for the department, manage the departmental budget while seeking a broad base of support for the department's programs and represent the department within the university community as well as within regional and national organizations.

Deadline for applications: May 1, 1989.

Qualifications: Earned Ph.D., excellent record of teaching, research and extramural funding; a demonstrated commitment to undergraduate and graduate education; evidence of outstanding leadership and administrative abilities.

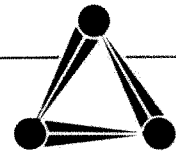
To apply: Send letter, resume, three letters of recommendation and transcripts to: **Chair, Department of Biology, Chair Recruitment Committee, c/o Dr. James D. Crum, Dean, School of Natural Sciences, California State University, San Bernardino, 5500 University Parkway, San Bernardino, California 92407.**

California State University at San Bernardino is the fastest growing of the 19 California State University campuses, with approximately 10,000 students, 350 full-time faculty, and 50 undergraduate and graduate degrees offered through both daytime and evening programs.

Equal Opportunity, Affirmative Action, Section 504, Title IX Employer.
(NW3165)A

Cambridge NeuroScience Research is a research and development company which focuses on Neurobiology and its applications. We have a new, well-equipped facility located in Cambridge, Massachusetts, close to M.I.T. and Harvard University. We are seeking a Group Leader and Staff Scientist for our Neurotropic Growth Factor Program.

Senior Scientist—Protein Chemistry



The candidate should have a Ph.D. with a minimum of 3 years' post-doctoral experience with state-of-the-art techniques, including HPLC and other microanalytic methods of protein purification and characterization. The successful applicant will have developed a reputation for independent research.

Staff Scientist—Cell Biology

The candidate should have a Ph.D. and at least three years' experience with the culture of cells from the nervous system.

These scientists will interact with molecular biologists, cell biologists, and neuropharmacologists within the Company and with the Company's extensive network of well-respected neuroscience consultants.

Cambridge NeuroScience Research offers a stimulating research environment with competitive salaries and excellent benefits, including Founders Stock. **Applicants for the above positions should send their curriculum vitae and the names of three references to: CNS Research, Human Resources Manager, One Kendall Square, Building 700, Cambridge, MA 02139, U.S.A.**

CNS RESEARCH

(NW3163)A

SCIENTIFIC DIRECTOR

AVT

A.V. THOMAS GROUP COMPANIES, the South India based major plantation and expanding biotechnology Organization, is seeking a Scientific Director for their Biotech Division. The Division has two seperate research-cum-production facilities with a capacity of producing 6 million plants per annum for export markets. The main facility is located in the Cochin Export Processing Zone and provides top class research facilities for investigation into plant micropropagation, plant health, cell-biology, biochemistry, horticulture and plant breeding. The division also plans to establish an advanced technology training centre for investigation into molecular biology and recombinent DNA technology.

The primary responsibility of the position is the direction of Research Groups covering the areas of Micropropagation, Cell biology, Somatic embryogenesis, Germplasm development, new technology mechanisation, Horticulture and large scale production systems, and supervision of 130 technical personnel.

Other responsibilities would include the constant monitoring of the research interaction and information flow with the sales and marketing agents/departments and production units, the continuation of productive relationships with local universities and government research stations and the maintenance of smooth interface between the biotechnology centre and the company's R & D programme on the field management of plantation crops and quality control unit of the Commodity Exports Department.

Candidate would be required to have a Ph.D in Plant Science with 10 or more years experience in the Plant Science related industries. A broad background in all areas of Plant Science and particularly Plant tissue Culture/Plant Biotechnology would be expected as well as demonstrated management skills.

Salary will be commensurate with qualification and experience and the company is offering an excellent fringe benefit package, free accommodation and car. Please submit a letter of application, curriculum vitae, statement of current research activities and the name and address of 3 references within 10 days of this advertisement. to:

(8144)A

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PATHOLOGY

A GRADUATE RESEARCH POSITION is available to work on a Medical Research Council funded project concerning the use of cultured skin keratinocytes as allografts. The post which is for twelve months is available from 1 February 1989.

Applicants should have experience in immunohistochemical and ultrastructural techniques.

Applications in writing with c.v. and names and addresses of two referees to **The Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP. PLEASE QUOTE 9114**

Further details can be obtained from Dr. Margaret Stanley, Telephone (0223) 333736. (8151)A

AFRC

AFRC INSTITUTE OF ARABLE CROPS RESEARCH ROTHAMSTED EXPERIMENTAL STATION HARPENDEN HERTS AL5 2JQ

PROTEIN CHEMIST

required to initiate and collaborate in studies of the structures and reaction mechanisms of plant enzymes with key roles in metabolism. It will include ongoing studies of the structure and active site chemistry of Ribulose Bisphosphate Carboxylase/Oxygenase (RuBisCO). The person appointed will be responsible for the design of mutant and chimaeric forms of the enzymes, and for analysis of their structures and catalytic properties. Ref. 779.

Qualifications: First or Upper Second Class Honours degree in Biochemistry, chemistry or a related subject, with at least four years postgraduate experience.

Appointment in the grade of Senior Scientific Office on scale £12,445-£17,032. Non-contributory superannuation.

MOLECULAR BIOLOGIST

required to join a group studying the structure and expression of cereal seed genes. The person appointed will collaborate in studies of cereal seed development, and the structure and control of expression of genes for major seed proteins. The work will involve construction and characterization of cDNA libraries, isolation of genomic clones, DNA sequencing and possibly *in situ* hybridization of cDNAs. Previous research experience and an interest in plant development will be an advantage. Ref. 778.

Qualifications: First or Upper Second Class Honours degree in Biochemistry, Molecular Biology or a related subject with at least two years relevant post-qualifying experience.

Appointment in the grade of Higher Scientific Officer on scale £10,026-£13,460. Non-contributory superannuation.

Applications with full cv and the names of two referees should be sent to **The Secretary** quoting the appropriate Ref. No. by 10 February.
We are an equal opportunities employer (8161)A

UNIVERSITY OF LEICESTER DEPARTMENT OF MICROBIOLOGY POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for a Research Associate post to work on development of new reagents for the diagnosis of tuberculosis. This post, which is funded by the World Health Organisation, is available immediately for one year. However, in line with WHO requirements, an application for renewal of funding will be made after one year. Salary (according to age and experience) on the scale IA: £9,865–£15,720.

Applications (including c.v. and the names of two referees) should be sent to either **Dr. P.W. Andrew or Dr. G.J. Boulnois, Department of Microbiology, P.O. Box 138, Medical Science Building, University Road, Leicester, LE1 9HN.** For informal enquiries call Dr. Boulnois on 0533–522944. (8037)A

POSTDOCTORAL POSITIONS MOLECULAR BIOLOGY, VIROLOGY, IMMUNOLOGY

Postdoctoral positions (3) are available for persons to participate in multidisciplinary experimental studies of Simian Immunodeficiency Virus expression relative to: (1) mechanisms of pathogenesis and development of effective immunoprophlaxis; (2) evaluation of antiviral drugs in vitro and in vivo; and (3) identification of humoral and cell-mediated immune responses to SIV infection. Please send curriculum vitae, a summary of research interests, and the names of three references to **Drs. Michael Murphey-Corb, Kenneth Soike,** or **Louis Martin,** respectively, **Delta Regional Primate Research Center, Three Rivers Road, Covington, LA. 70433.** (NW3160)A

POSTDOCTORAL POSITION

Cellular Immunologist/ Molecular Biologist

Postdoctoral position in mucosal immunology to study immunmechanisms in the gastrointestinal tract and their relationship to endocrine function. Preference will be given to candidates with training in cellular immunology and/or molecular biology. Salary is paid according to BAT IIa/BAT III amounting to approx. $33,000 per annum. Send curriculum vitae and names of three references to: **Dr. Rudolf Hatz, Department of Surgery, Klinikum Grosshadern, Ludwig Maximilians University of Munich, Marchioninistr, 15, 8000 Munich 70, Federal Republic of Germany.**

(W5768)A

AFRC Institute of Food Research Reading Laboratory

Higher Scientific Officer/Senior Scientific Officer

A Physical chemist is required for a new project on the crystallisation of fats used in food manufacture. Functional properties of triglyceride mixtures will be studied in both bulk phase and emulsion systems. Technical support will be provided.

Qualifications: Honours degree (I or IIi) in Chemistry or related discipline, preferably with a PhD. Experience with x-ray diffraction, especially AND, DSC and NMR would be advantageous. At least two years relevant experience is required for HSO and at least 4 years for SSO.

Salary £10,026-£13,460 — HSO £12,445-£17,032 — SSO.

Please write for an application form to the Personnel Officer, AFRC Institute of Food Research, Reading Laboratory, Shinfield, Reading RG2 9AT.

Please quote reference (46/88). Closing date: 6th February 1989.

The AFRC is an equal opportunities employer. (8163)A

THE KENNEDY INSTITUTE OF RHEUMATOLOGY CELL ENZYMOLOLGY UNIT

A recently qualified graduate is required to join a small and enthusiastic group working on inherited disorders of lysosomal function. The scientist will be studying lysosomal enzymes in different types of lymphocyte and lymphold cell, using a variety of contemporary biochemical and immunological techniques. Interest in basic aspects of cell biology would be an advantage.

The appointment is for 18 months with the possibility of renewal thereafter. The starting salary is up to £10,710 inclusive of London Weighting. Applications including a c.v. and the names of two referees should be sent to The General Secretary, Kennedy Institute of Rheumatology, 6 Bute Gardens, Hammersmith, London W6 7DW by 9 February 1989.

(8125)A

AFRC Institute of Food Research Reading Laboratory

Scientific Officer/Higher Scientific Officer

A Food materials scientist is required for a 2 year EEC-funded project assessing Mozzarella cheese functionality by sensory and instrumental means. The work will require collaboration with scientists in other specialisms and with industrial technologists.

Qualifications: Degree in Food Science, Food Technology or a related subject or HNC with relevant experience. At least 2 years' experience is required for appointment to the higher grade.

Salary: £8,574-£10,994 — SO £10,026-£13,460 — HSO.

Please write for an application form to the Personnel Officer, AFRC Institute of Food Research, Reading Laboratory, Shinfield, Reading RG2 9AT.

Please quote reference: 52/88. Closing date 6th February 1989.

The AFRC is an equal opportunities employer. (8162)A

ACADEMIC PHYSIOLOGIST

The Department of Anesthesiology of Loyola University Stritch School of Medicine, Maywood, Illinois is recruiting a physiologist for a faculty position at the Assistant Professor level to work in a stimulating environment that includes excellent research laboratory. The candidates for this position are expected to have a strong commitment to innovative research in cardiovascular and respiratory physiology and ability to run large animal experiments in collaboration with the departments physician faculty and resident trainees. The salary is competitive and Loyola University is an Equal Opportunity Employer.

Please submit curriculum vitae, reprints, a statement of research interests, and arrange to have three letters of recommendations sent directly to:

Tadikonda L.K. Rao, M.D
Department of Anesthesiology
Loyola University
2160 S. First Avenue
Maywood, Illinois 60153 (NW2895)A

MOLECULAR VIROLOGIST

A staff position is available for a person with experience in the molecular biology of primate viruses. The successful candidate would be expected to become involved with research programs involving simian immunodeficiency disease as well as to establish his/her own area of research. Ongoing research includes studies investigating the interrelationships of opportunistic viruses with Simian Immunodeficiency Virus. The applicant would be expected to obtain research support as well as to work collaboratively with other investigators. Please send résumé, a summary of research interests, and the names of three references by Feb. 15 to: **Dr. Michael Murphey-Corb, Delta Regional Primate Research Center, Three Rivers Road, Covington, LA 70433.** (NW3159)A

LECTURER – VERTEBRATE AND FIELD BIOLOGY

The Program in Ecology, Evolution, and Behavior of the Department of Biology at Princeton University has a full-time opening or two half-time openings at the rank of Lecturer for a one year renewable appointment beginning in September, 1989. Duties include teaching a Vertebrate Biology Laboratory course with a strong physiological component, teaching a Field Biology course, and advising the independent work of several undergraduates in these fields. The courses are given during the Fall term, in collaboration respectively with Robert Lisk and Henry Horn, and there is time in the Spring term for the candidate's own research. A PhD in a relevant discipline is required. Applicants should specify whether they wish a half-time or full-time appointment. The closing date for applications is March 3, 1989. Applicants should send a curriculum vitae and arrange for three letters of reference to be sent to **Robert Lisk, Search Committee, Program in Ecology, Evolution, and Behavior, Guyot Hall, Princeton University, Princeton, NJ, 08544-1003.**

Princeton University is an Equal Opportunity/Affirmative Action Employer. (NW3091)A

NATIONAL KIDNEY RESEARCH FUND

RESEARCH FELLOWSHIPS

The National Kidney Research Fund (NKRF) is to offer two Fellowships, one clinical and one non-clinical in research areas related to renal disease. The Fellowship may be held in any suitable department in the UK. Fellows will be appointed for three years in the first instance, but an extension for a further two years will be possible. A grant of £5,000 per annum for research expenses will be available to the host department. The clinical Fellowships salary will be between £13,470 and £19,610 depending on experience. The non-clinical Fellowship salary will be at the appropriate post-doctoral level.

Closing date for receipt of applications 6th March 1989.

Application forms may be obtained from:

The Director-General, NKRF, 42 Lower Marsh, London SE1 7RG. (8099)E

THE ROYAL VETERINARY COLLEGE
University of London

POST-DOCTORAL RESEARCH FELLOWSHIP IN MOLECULAR BIOLOGY

LATENCY OF EQUID HERPESVIRUS I

Applicants will be invited to participate in an existing project investigating the role of latency, particularly of the immediate early proteins in the control of EHVI. Further information is available from Dr N Edington. Technical help will be available for three years.

SALARY according to age and experience will on the Universities Research Scale 1A, not less than £11,515 per annum, including London Allowance. Eligibility for Universities' Superannuation Scheme.

Applications with a cv and the names of two referees should be sent to the **Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU.** (8136)E

Prize Postdoctoral Fellowship

The Center for Photochemistry and Photobiology at the University of Chicago invites applications for the James Franck Postdoctoral Fellowship for 1989. The James Franck Fellow will work on an interdisciplinary project dealing with photochemical reaction centers for bacteria, cyanobacteria, green algae or plants using a combination of the techniques of molecular genetics, biochemistry, absorption and magnetic resonance spectroscopy, X-ray crystallography, and ultrafast fluorescence spectroscopy. Faculty supervisors include Professors G. Closs, G. Fleming, M. Garavito, R. Haselkorn, G. Lamppa, L. Mets and J. Norris. The fellowship carries a 12-month stipend of $32,000. There are no restrictions on age, citizenship or length of time since the Ph.D. was earned. Please address inquiries to **R. Haselkorn, Director of the Center, 920 E. 58th Street, Chicago, IL 60637.** (NW3150)E

SCHOOL OF PHARMACY
UNIVERSITY OF LONDON

TOXICOLOGY UNIT

APPLICATIONS ARE INVITED for the above post available immediately for a fixed term of three years. This project involves investigations to understand basic mechanisms of chemical induced toxicity. The study will concentrate on the roles of pyridine nucleotide depletion and poly ADP-ribosylation in cellular toxicity.

Applicants should have a good honours degree in Biochemistry or a related subject. Candidates with a Ph.D may be appointed as a Research Fellow. Salary on RA 1B scale for Research Assistants (£8,675-£11,680 + £1,650 London Weighting) or RA 1A for Research Fellows (£9,865-£12,120 + £1,650 L.W.) Informal enquiries to Dr G M Cohen (01-837-7651 Extn 71).

Applications in the form of a CV including names and addresses of two referees to: **The Assistant Secretary, School of Pharmacy, University of London, 29-39 Brunswick Square, London WC1N 1AX.**

Closing date for applications: 3 weeks after publication date. (8113)E

University of York
Department of Biology
CANCER RESEARCH UNIT

Post-doctoral Positions

Two positions are available in the above Unit which specialises in cancer aetiology relating to chemicals.

Position 1 is a one-year fellowship with the possibility of extension up to a maximum of 3 years in total, to investigate the role of oncogene activation and chromosome alterations in human colon cancer, using tissue culture techniques.

Position 2 is a two-year fellowship funded by the European Commission as part of the collaborative programme on 'Biomonitoring of human populations exposed to genotoxic environmental chemicals'.

Applicants for both posts should have, or expect to gain shortly, a PhD in a relevant topic.

Salary for both positions will be in the range 1A for Research and Analogous Staff (£9,865-£15,720) per annum.

Informal enquiries to Dr Colin Garner on 0904 432903.

Four copies of applications, with full curriculum vitae and naming two referees should be sent by Monday 6 February 1989 to Personnel Office, University of York, Heslington, YORK, YO1 5DD, from whom further particulars are available. Please quote advertisement reference number 7/6277. (8106)E

UNIVERSITY OF BIRMINGHAM
School of Physics & Space Research

Research Fellowship (Ref PH 5399)

STUDY THE SUN WITH THE SOLAR PHYSICS GROUP

We have stations in Hawaii, Western Australia and Tenerife and have a major SERC award to expand and develop this network. The globa oscillations of the Sun studied by the group enable one to probe the depths of the Sun and to study its physics to a precision rare ir Astronomy. Applications are invited from PhD level candidates ir Physics, Astronomy or Control Engineering for a person who car contribute substantially to the development and implementation o the stations, the observing programme or the data interpretation Prospective applicants may wish to contact Professor G Isaak, Schoo of Physics and Space Research (tel 021-414 4575), for an informa discussion of this exciting research opportunity. It is expected that th appointment will be within the first three points of the Researcl Fellow 1A scale, £9,865–£11,070 plus superannuation.

For further particulars of the above post and an application form, tele phone 021-414 6383 quoting reference number PH 5399. Application (3 copies) should be sent to the **Senior Assistant Registrar, Faculty o Science, PO Box 363, Birmingham B15 2TT** by 10 February 1989.

AN EQUAL OPPORTUNITIES EMPLOYER

(8102)E

Applications are invited for the

M.C. Chang Postdoctoral Fellowships

in

Male Fertility Research

supported by the Andrew W. Mellon Foundation at

The Worcester Foundation for Experimental Biology

The Worcester Foundation's Male Fertility Program emphasizes multidisciplinary approaches to the study of male reproductive biology utilizing state-of-the-art techniques in biophysics, biochemistry, and cell and molecular biology. The faculty and their research interests are:

Lawrence J. Dangott: Receptors and mechanisms of chemical signaling in spermatozoa

Grant Fairbanks: Mechanism of sperm plasma membrane modification during epididymal maturation

Daniel L. Kilpatrick: Gene transcription during spermatogenesis using transgenic mice; paracrine function of testicular peptides

John A. McCracken: Studies on sperm maturation, motility, and capacitation using surgical diversion of the male and female ducts

Clare M. O'Connor: Regulation of protein modification and turnover during gametogenesis

George B. Witman: Control of sperm motility during maturation and capacitation; phosphorylation of sperm flagellar proteins

David E. Wolf: Diffusion and control of membrane regionalization, sperm maturation, capacitation, and fertilization

Carol A. Ziomek: Membrane structure and cell polarity in early mouse development

The Worcester Foundation is a private, nonprofit biomedical research institute offering excellent facilities and a stimulating research environment. Please send curriculum vitae and names of three references to the faculty member of interest, c/o **Male Fertility Program, Personnel Office, Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.**

BP

BP Research Fellowships

The Royal Society of Edinburgh invites applications for these prestigious 3 year post-doctoral Research Fellowships, to be held in Scottish Universities and Central Institutions.

Fellowships will be available for independent research in:

Mechanical Engineering	Solid State Sciences
Information Technology	Organic Chemistry (except natural product and biological chemistry)
Geological Sciences	

Applicants must have a Ph.D. and be able to demonstrate an excellent record of innovative research. Preferred age range 28–35. Salaries will be on University Research grades 1A and 2 (in the range £12,150 to £17,630) with placement according to experience.

Application forms are available from **The Executive Secretary, The Royal Society of Edinburgh, 22–24 George Street, Edinburgh EH2 2PQ,** and must be returned by 1st March 1989.

(8101)E

EMBO

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1989 AWARDS

Next deadline: 10 February 1989

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are usually awarded initially for one year, but with the possibility of renewal for a second year. In cases of exceptional scientific merit, however, the selection committee can award a 2-year fellowship. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 10 February 1989. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 17 April 1989.

Application forms and further details may be obtained from **Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany.** Inquiries should be accompanied by a self-addressed adhesive label. (W5559)E

STUDENTSHIPS

NATIONAL KIDNEY RESEARCH FUND

STUDENTSHIPS

The National Kidney Research Fund (NKRF) is to offer three Studentships in research areas related to renal disease. Heads of department are invited to apply for studentship allocations. Student stipends vary between £3,690 p.a. (outer London) £4,500 (London) plus approved student fees and contribution to departmental research expenses.

Closing date for receipt of application 6th March 1989.

Application forms may be obtained from:

The Director-General, NKRF, 42 Lower Marsh, London SE1 7RG. (8100)F

ROYAL POSTGRADUATE MEDICAL SCHOOL (University of London)

DEPARTMENT OF SURGERY

NUTRITIONAL CONSULTATIVE PANEL SCHOLARSHIP

Applications are invited for a three year research studentship into "The Effect of Dietary Calcium on the Development of Human Colorectal Cancer". The successful applicant will be registered for a higher degree. The studentship is funded by the Nutritional Consultative Panel and the terms and conditions are similar to those for an MRC studentship.

Candidates should possess a good honours degree in biochemistry, pharmacology or related discipline. The project will be supervised by Professor R C N Williamson, M.A., M.D., M.Chir, F.R.C.S., Professor and Director of Surgery, Royal Postgraduate Medical School.

Applications together with a Curriculum Vitae and the name and addresses of two referees should be sent as soon as possible to **Mr P W Davies, Departmental Superintendent and Assistant General Manager (Surgery), Department of Surgery, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0NN.** (8043)F

KING'S COLLEGE LONDON BIOMEDICAL SCIENCES DIVISION

POSTDOCTORAL FELLOWSHIP

Applications are invited for a postdoctoral fellowship (3 years) in an active research group, studying the regulation and mechanism of insulin secretion.

Applications should preferably have training or research experience in molecular biological techniques applicable to the study of secretory processes.

Starting salary on Research Fellow 1A Scale in range £11,515 – £13,800 per annum (including London Allowance).

Applications, including Curriculum Vitae and the names of two referees, to:

Professor S L Howell, Biomedical Sciences Division, King's College London, Campden Hill Road, Kensington, London, W8 7AH. (8114)E

FRIEDRICH MIESCHER INSTITUT BASEL, SWITZERLAND

POSTDOCTORAL FELLOWSHIP

Applicants are invited for an internally funded fellowship of up to 3 years maximum duration to join an established team working on the role of methylation in eucaryotic gene regulation and on the interactions of transacting factors (*in vitro* and *in vivo*) with regualtory elements of hormonally controlled genes. Emphasis will be made on the tissue specific expression of genes. The Institute provides outstanding facilities in a purely research environment.

Position is available in the fall 1989. Candidates should have a good background in cell biology, molecular biology or biochemistry.

Applications (with C.V.) should be sent to Dr J.P. Jost, Friedrich Miescher Institut, P.O. Box 2543. CH 4002 Basel, Switzerland. (W5739)E

UNIVERSITY OF SURREY

DEPARTMENT OF CHEMICAL AND PROCESS ENGINEERING

Research Studentship

Applications are invited from newly qualified Engineers (Chemical or Mechanical) or Scientists (Physics or Materials Science) to work on a study of impact attrition of particulate solids. The project is funded by a grant from the International Fine Particle Research Institute, and aims to relate the attrition and breakdown of particulate solids to their fundamental physical and structural properties and the impact process conditions. Practical aspects concern preparation of test materials, characterisation of flaws and of impact damage. Theoretical aspects involve analysis of stress field, and of formation and propagation of cracks by the use of fracture mechanics principles. The work is of multi-disciplinary nature, and requires a student with flair and initiative. The projects is for a duration of three years leading to a PhD Degree. The University fees and student maintenance are covered by the grant. In the absence of any suitable British applicants, candidates from other nationalities could be considered. Some financial assistance is available for travel to England.

Further details may be obtained from Dr M Ghadiri, tel 0483-509270. Applications in the form of a curriculum vitae including the names and addresses fo two referees should be sent to **Dr M Ghadiri, Department of Chemical & Process Engineering, University of Surrey, Guildford, Surrey GU2 5XH, England. Ref N.** (8128)F

BRITISH MUSEUM (NATURAL HISTORY)

POSTGRADUATE RESEARCH STUDENTSHIPS

Two studentships will be available, tenable for 3 years at the British Museum (Natural History) commencing October 1989.

Applications are invited for the following five research projects, the two to receive studentships will be selected following interviews in March.

Arrangements will be made with an appropriate university for joint supervision of studentships and registration for a higher degree.

Department of Zoology
Taxonomy and biology of fish lice (Crustacea: Branchiura).

Department of Entomology
Molecular evolution related to chromosome evolution in anopheline mosquitoes.

Department of Palaeontology
British Silurian Bryozoa.

Department of Botany
Scanning Electron Microscope investigation of the structure, ornamentation and ontogeny of the oosporangial wall in selected Charalean taxa.

Department of Mineralogy
Structure and composition of boron minerals by soft X-ray spectroscopy and related techniques.

A wide range of scientific facilities is available and students will have full access to the Museum's extensive libraries.

Eligibility
Applicants must be ordinarily resident in Great Britain, and have a first or second class honours degree; a student graduating in 1989 may be offered an award subject to his/her degree results reaching the required standard.

Application forms, conditions of the awards and further information on projects may be obtained from the **Assistant to the Director, British Museum (Natural History), Cromwell Road, London SW7 5BD.**

Closing date for receipt of completed forms is 17 February, 1989.

(8104)F

COURSES & CONFERENCES

UNIVERSITY COLLEGE LONDON

Science and Engineering Research Council Centre for Biochemical Engineering

Biochemical Engineering Postgraduate/Postexperience Taught Course Studies

UCL is a world leader in postgraduate/postexperience teaching of biochemical engineering for chemical engineers, bioscientists and others with appropriate training. The Master's Degree course is suitable for recent graduates. It is used also by companies for post-experience training and complements an annual one week intensive course. Those completing the MSc are strongly sought after by industry.

UCL has an international reputation in the field of biochemical engineering research and has received special government support so that it is superbly well equipped both at laboratory and pilot plant levels. The calendar year MSc course starts in October and makes extensive use of these research facilities to complement biochemical engineering lectures and studies of process engineering or biological science according to background. Biological scientists undertake a three month process design project, while chemical engineers complete a research project alongside the multidisciplinary research team.

Details from Miss Valerie Potter, Department of Chemical and Biochemical Engineering, University College London, Torrington Place, London, WC1E 7JE, UK. (8110)C

INTERNATIONAL CONFERENCE

ATRIAL PEPTIDES AND THEIR NOVEL ANALOGUES
A rational approach to cardiovascular diseases?

15th/16th March 1989, Royal College of Physicians, London

This two-day international conference, organised by IBC Technical Services, will provide a comprehensive update on the progress being made in research on atrial natriuretic factor. Although the factor was identified only six years ago, it has already been purified and sequenced, and a number of congeners, analogues and even antagonists are under development. Native forms of ANF are in clinical trials, and at least one marketing application is in the pipeline. Potential indications include congestive heart failure, hypertension, renal and hepatic disease and asthma.

Advances in Separations in

Biochemistry Cell Biology and Biotechnology

6th International Conference on Partitioning in Aqueous Two-Phase Systems

Assmannshausen/Rhein
Aug. 27–Sept. 01, 1989

Deadline for abstracts: April 15th, 1989
Registration deadline: May 15th, 1989

Scientific Programme

— Theory and Analysis
— Partitioning of Biopolymers:
Separations of proteins, nucleic acids etc. by extraction, CCD and chromatographic techniques, application of affinity agents
— Partitioning of cells and subcellular organelles (including immuno affinity techniques)
— New Methodology and Emerging Technology (including new phase systems and polymer derivatives)
— Biotechnological Applications: downstream processing, extractive bioconversions and liquid-liquid extractions

Local Organizers
W. Müller, FRG
M.-R. Kula, FRG

Address for Correspondence
All mail including registration, abstract forms should be sent to:

Advances in the applications of monoclonal antibodies in clinical oncology

21ST-23RD JUNE 1989

This 6th International Meeting will highlight advances in both fundamental aspects of monoclonal antibodies and applications in diagnosis and therapy of malignant disease. The meeting will be of interest to laboratory scientists, clinicians and members of the biotechnology and pharmaceutical industry.

Topics include:
Humoral and cellular immune control of tumour growth • The importance of antibody dilution • Transport of antibodies into tumours and studies on the internalisation • Tumour site activation of cytotoxic agents • Antibody engineering • Clinical trials with hybrid and chimeric antibodies • Tumour glycoproteins • Biocompatibility and cellular processing of immunoconjugates • Macrocycle chemistry • Technetium labelling of antibodies • Studies of antigen binding sites • Idiotypic antibodies as vaccines • Systemic and reigonal antibody therapy • Radiodosimetry

Speakers and Chairpersons include:
Dr D Allen, Prof K D Bagshawe, Dr R Begent, Dr Benveniste, Dr L Berneman, Dr P Beverley, Sir Walter Bodmer, Dr K Bosslet, Dr R Bradwell, Dr M Clark, Dr N Courtenay-Luck, Dr A Dagleish, Sir Colin Dollery, Dr R Duncan, Prof D Evans, Dr A A Epenetos, Dr C Foster, Mrs V Hird, Dr R K Jain, Prof P Kenemans, Dr G Winter, Prof A F LoBuglio, Dr S Mather, Dr S Matzku, Prof C Meares, Dr M Ritter, Dr J Rothbard, Prof K Sikora, Dr J Taylor-Papadimitriou, Dr B Wessels.

Course Organiser:
Dr A A Epenetos, Senior Lecturer and Constultant in Clinical Oncology, RPMS, Hammersmith Hospital and Imperial Cancer Research Fund, UK

Course fee: £245

Course enquiries: Dr A A Epenetos (tel: 01–740 3149)
Two half days will be open for paper presentations. Abstracts will be considered for oral and/or poster presentation. Manuscripts will be considered for publication by the International Journal of Cancer as a Supplement Issue devoted to this meeting.

Closing date: for registration and submission of abstracts 1st May 1989
for manuscripts 21 June 1989

Application forms, abstract forms and further details
may be obtained from: School Office (SSC), Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0NN
Tel: 01–743 2030 ext 2242 (8119)C

TECANICAL COURSE
ON
HPLC

29th to 31st March 1989

Organised by Harish Patel and Alan D.B. Malcolm
at
Department of Biochemistry
Charing Cross and Westminster Medical School
Fulham Palace Road, London W6 8RF

The course consists of lectures and practical demonstrations.

Registration fee, £95, for participants from non-profit making institutes and £125 for commercial laboratories.

For an application form and provisional programme contact Linda Readings at the above address (01-741 1858).

Closing date for registration: 10th March 1989. (8159)C

UNIVERSITY OF ABERDEEN

M.Sc. in Clinical Pharmacology

Applications are invited for a 12 month full-time post graduate course leading to the degree of M.Sc. in Clinica Pharmacology. The course consists of lectures and practi cal work, in addition to an original research project. The course is designed for medical practitioners or non-medi cal graduates with appropriate qualifications in Pharmacy or Pharmacology or a related subject.

Further details may be obtained from the **Secretary Clinical Pharmacology Unit, Department of Medicine & Therapeutics, University of Aberdeen, Foresterhill Aberdeen AB9 2ZB, to whom application for admission to the course should be made.** (8138)C

COURSE ON SEPARATION TECHNIQUES IN PROTEIN PURIFICATION

Organised by Harish Patel and Alan D.B. Malcolm
Department of Biochemistry
Charing Cross and Westminster Medical School
Fulham Palace Road, London W6 8RF
In conjunction with
PHARMACIA LTD
20th to 22nd March 1989

The course is designed to give practical training in separation techniques.

Registration fee (with lunch and coffee): £95, for participants from non-profit making institutes and £125 for commercial laboratories.

For an application form and provisional programme contact Linda Readings at the above address (01-741 1858).

Closing date for registration: 6th March 1989. (8160)C

ASSISTANTSHIPS

Imperial College of Science, Technology & Medicine

Positions in Molecular Parasitology Postdoctoral Scientist and Graduate Research Assistant

Applications are invited for a Postdoctoral scientific position and a graduate Research Assistantship studying the immunology and molecular biology of nematode parasite infections. Each position is funded for up to 3 years, within the Parasitology research group in the Department of Pure and Applied Biology at South Kensington.

The Postdoctoral project, under the supervision of Dr. R.M. Maizels, centres around identifying key molecular interactions between nematode parasites and their mammalian hosts with a particular focus on direct and indirect (interleukin-mediated) stimulation of host cell subpopulations. The graduate Research Assistant position will be supervised by Dr. J.E. Bradley and is funded for 3 years by the MRC. The project will involve the molecular characterisation of diagnostic antigens of the medically important parasite *Onchocerca volvulus*. Other interests related to these projects are the antigenic nature of the nematode surface, enzymes and other molecules secreted by parasites, interactions with the host immume network, and the epitopic structure of immunologically important nematode antigens.

Applicants with interests in these areas and/or experience with relevant immunological, molecular biological or biochemical techniques should apply, enclosing a C.V. and names of two referees, to the appropriate supervisor at the **Department of Pure and Applied Biology, Imperial College of Science, Technology and Medicine, Prince Consort Road, London SW7 2BB,** by 28 February 1989. (8149)P

SEMINARS & SYMPOSIA

GENOME MAPPING AND SEQUENCING

April 26 - 30, 1989

Organized by:

Charles Cantor, *Columbia University*
Maynard Olson, *Washington University*
Richard Roberts, *Cold Spring Harbor Laboratory*

The meeting will focus on:

Ongoing mapping endeavors
New methodologies for mapping and sequencing
Techniques for the analysis of maps and sequences

The organizers invite submission of abstracts concerning recent work for oral or poster presentations by **February 16, 1989.** Requests for registration materials should be forwarded to:

Meetings Coordinator

IMPERIAL CANCER RESEARCH FUND DNA TUMOUR VIRUS MEETING 1989

The Imperial Cancer Research Fund is sponsoring a meeting on DNA Tumour Viruses to be held in Churchill College, Cambridge, England from *24th to 29th July, 1989* (5 days). The subject of meeting will be the molecular biology of small DNA tumour viruses, particularly polyoma virus, SV40 and adenoviruses. It will replace for this year the annual Cold Spring Harbour DNA tumour virus meeting.

The meeting is open to all interested research workers. The scientific programme will include oral presentations and posters. The cost for registration, accommodation, food and the abstract book will be £260.

Anyone interested in attending the meeting should apply immediately for further details to: **Mrs. Clare Middlemiss, ICRF DNA Tumour Virus Meeting Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, England.** (8124)M

WORKSHOP

CHROMOSOME 21: IMPACT OF THE NEW GENOME TECHNOLOGY IN HUMAN GENETICS

Santa Margherita Ligure Genoa (Italy) May 18-20, 1989

SPONSORED BY: The European Molecular Biology Organization The International School of Pediatric Sciences
ORGANIZERS: Nicoletta Sacchi (Frederick, USA); Paolo Durand (Genoa, Italy); Giovanni Romeo (Genoa, Italy); Giorgio Bernardi (Paris, France)
The Worshop will focus on the new methodologies used to investigate human genetic diseases of unknown molecular basis. The strategies for identifying genes responsible for inherited disorders and cancer: the methods of analysis, cloning and sequencing of large chromosomal fragments, and the production of animal models of desired genotype will be addressed. The smallest human autosome, chromosome 21, will serve as a model system to illustrate the actual contributions that may derive from genome technology: the understanding of diseases of diverse genetic etiology, such as aneuploidies (down syndrome) mono/polygenic inherited conditions (alzheimer disease) and cancer.
SPEAKERS: W. Ansorge (Heidelberg, Germany); S. Antonarakis (Baltimore, USA); G. Bernardi (Paris, France); C Cantor (New York, USA); M. Capecchi (Salt Lake City, USA); A. Carrano (Livermore, USA); D. Cox (San Francisco, USA); A. deKlein (Rotterdam, The Netherlands); C. Epstein (San Francisco, USA); J. Gearhart (Baltimore, USA); R. Gemmill (Scottsdale, USA); Y. Groner (Rehovot, Israel); J. Gusella (Boston, USA); T. Hassold (Atlanta, USA); J. Ihle (Memphis, USA); E. Karson (Bethesda, USA); E. Lee (San Diego, USA); H. Lehrach (London, England); T. Papas (Frederick, USA); D. Patterson (Denver, USA); P. Pearson (Leiden, The Netherlands); A. Poustka (Heidelberg, Germany); G. Romeo (Genoa, Italy); D. Schlessinger (St. Louis, USA); N. Sacchi (Frederick, USA); N. Shimizu (Tokio, Japan); C. Smith (New York, USA); G. Stewart (Ann Arbor, USA); R. Tanzi (Boston, USA); D. Warburton (New York, USA); R. Worton (Toronto, Canada)
REGISTRATION AND INFORMATION: International School of Pediatric Sciences Telephone 039-10-383628; Direzione Scientifica 039-10-5636324; Istituto G. Gaslini 039-10-5636326; 16148 Genoa (Italy) Telefax 039-10-5636461
The Workshop is open to 40 participants. Preference will be given to applicants from Western Europe and Israel willing to present pertinent scientific contributions at the poster session. Deadline for application and poster abstract submission: February 28, 1989. **No Registration Fee.** Applicants must be able to cover their own travel and lodging expenses. (W5766)V

Smith Kline & French Research Symposium

ION TRANSPORT

12-14th April, 1989

CAMBRIDGE, U.K.
CO-CHAIRMEN: R. G. HILL AND T. J. RINK

This meeting will provide a general perspective on ion transport as well as a forum for the presentation of new developments. Each session focuses on a particular area of ion transport and will encompass mechanistic, molecular, physiological and pharmacological aspects of the topic.

Final Programme:

1. ION PUMPS

Chairman: I. M. Glynn, Cambridge
Speakers: G. Sachs, Los Angeles
S. J. D. Karlish, Rehovoth
C. W. Slayman, New Haven

2. IONS AND FLUID TRANSPORT

Chairman: A. W. Cuthbert, Cambridge
Speakers: J. C. Ellory, Oxford
R. Greger, Frieburg
Q. Al-Awqati, New York

3. VOLTAGE-GATED CHANNELS

Chairman: A. F. Huxley, Cambridge
Speakers: B. Hille, Seattle
T. B. Bolton, London
P. Hess, Boston
R. W. Aldrich, Stanford

4. RECEPTOR-OPERATED CHANNELS

Chairman: L. L. Iversen, Harlow
Speakers: T. J. Rink, Welwyn
M. L. Mayer, Bethesda
E. Barnard, Cambridge

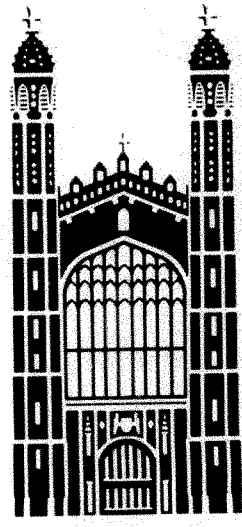
5. MODULATION OF ION CHANNELS

Chairman: D. Noble, Oxford
Speakers: H. Reuter, Berne
A. Dolphin, London
F. Hoffman, Saarlandes

SK&F
A SMITHKLINE BECKMAN COMPANY

6. EVENING WORKSHOP

on Models of ion permeation through channels. Discussion led by D. T. Edmonds, Oxford and S. B. Hladky, Cambridge



Poster session: Posters are invited from participants and abstracts will be included in the Symposium Proceedings. Closing date for receipt of abstracts is *13th March 1989.*

Registration: Details are available from Ms M. H. Hancock, Smith Kline & French Research Ltd., The Frythe, Welwyn, Herts AL6 9AR. Telephone: (0707) 325111, Ext. 3894. The registration fee of £180.00 (£90.00 for registered undergraduate and graduate students) includes welcome buffet, conference dinner, all other meals, accommodation for three nights and a copy of the Symposium Proceedings.

Sessions are in the Corn Exchange; accommodation in King's College.

Organising committee: C. D. Benham, D. J. Keeling, B. K. Leigh. Smith Kline & French Research Ltd., The Frythe, Welwyn, Hertfordshire AL6 9AR. Telephone: (0707) 325111.

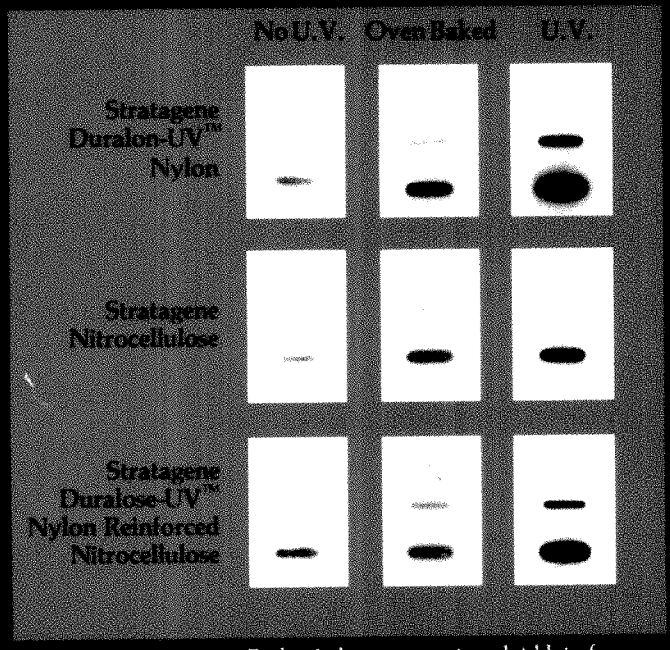
ASTRONOMY BEFORE STONEHENGE

CELL BIOLOGY/MOLECULAR BIOLOGY

product review

- Binding RNA or DNA to nitrocellulose, nylon or hybrid membranes for Northern, Southern, dot, or slot blot analysis (1, 2).
- Linking DNA to filters for bacterial or phage library screening (3).
- DNA nicking in agarose gels prior to blotting (4).
- Dimer formation to perform partial digests for rapid gene mapping (5).
- Confirming Rec + versus RecA – genotypes in E.coli strains through UV sensitivity testing (6).

The UV Stratalinker is supplied with 254nm UV bulbs and is available in two convenient sizes: the UV Stratalinker 1800 (internal dimensions) -14″w × 8″h × 8″d for small membranes, and the UV Stratalinker 2400 - 19″w × 8″h × 14.5″d to fit large membranes. Each has an easy to read L.E.D. display with built-in touch pad. All parts and labor are guaranteed for 1 full year.



Stratagene's economical UV Stratalinker puts an end to expensive vacuum ovens and brittle, baked filters. Why wait 2 hours when you can accomplish more in 30 seconds? Call today for more information about the Stratagene UV Stratalinker 1800, 2400 and our specially designed membranes.

As can be seen in the accompanying figure, Stratagene's nitrocellulose, Duralon-UV™ nylon, and Duralose-UV™ nylon-reinforced nitrocellulose membranes provide extremely high nucleic acid binding capacities with minimal background. When used in conjunction with the UV Stratalinker, Stratagene's economical uncharged nylon membranes display the highest signal to noise ratios of any nylon or nitrocellulose membranes tested, including those of major competitors. Each lot is quality controlled for optimal performance in the UV Stratalinker, providing the most rapid, cost effective, and sensitive system for performing Southern blots, Northern blots, slot blots, colony lifts and plaque lifts available anywhere.

Each window represents a slot blot of lambda DNA applied at concentrations equivalent to 0.1, 1.0, and 10 copies per mammalian genome diluted in 5 micrograms of calf thymus DNA and hybridized with a 32P-labeled lambda DNA probe. The film was developed after an overnight exposure.

The effects of altering the incident energy for crosslinking nucleic acids to nylon membranes. The peak signal intensity is at approximately 0.12 Joules. The significant drop in signal intensity at energies below and above 0.12 Joules demonstrates the limited optimal range for U.V. treatment.

the care to meet, to know, to understand

Ares-Serono Symposia is an independent foundation, created in 1971, to promote scientific research in all disciplines which contribute towards improving human health. This aim is pursued by means of congresses, courses, seminars and specialized studies.

Some of the international meetings scheduled for 1989 are:

Unexplained Infertility: Basic and Clinical Aspects
Rome, Italy/March 7-8
Scientific Organization: G. Benagiano (I), K.J. Catt (USA) and G. Spera (I)

Symposium on the Pathogenesis and Control of Viral Infections
Beijing, Republic of China/April 24-26
Scientific Organization: F. Aiuti (I), Z. Zonghan (PRC) and S. Guoxian (PRC)

th Workshop on Development and unction of the Reproductive Organs
ouraine, France/May 23-25
cientific Organization: N. Josso (F)

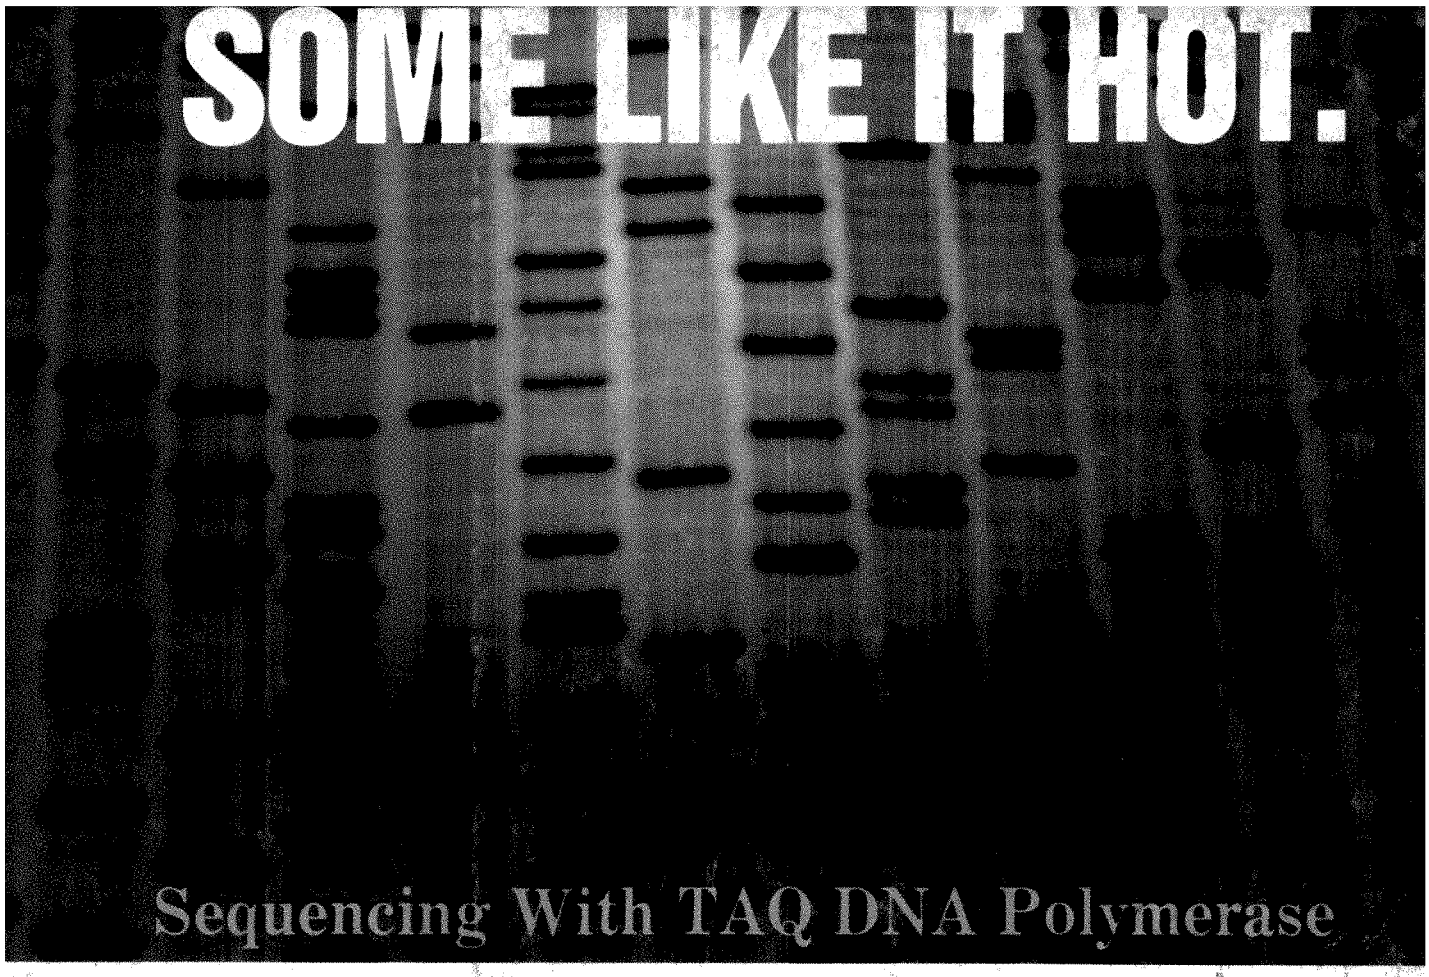
1st International Congress on G.I.F.T.: from Basics to Clinics
Rapallo, Italy/June 8-10
Scientific Organization: R.H. Asch (USA) and L. De Cecco (I)

Membrane Technology in Clinical Pathology, Biochemistry and Pharmacology
L'Aquila, Italy/June 19-23
Scientific Organization: R. Verna (I), R.P. Blumenthal (USA), J.A. Hannover (USA) and R.P. Garay (F)

Cardiovascular and Neurological Function and Ovarian Secretions
Dubrovnik, Jugoslavia
Aug. 31-Sept. 1
Scientific Organization: F. Naftolin (USA)

Establishment of a Successful Human Pregnancy
Cambridge, U.K./September 21-23
Scientific Organization: R.G. Edwards (UK)

Developmental Endocrinology
Geneva, Switzerland/October 23-24
Scientific Organization: P.C. Sizonenko (CH) and M. Aubert (CH)



Advanced Course in Molecular Pathology and Biotechnology
Rome, Italy/November 6-10
Scientific Organization: L. Frati (I)

Stratagene's new ThermalBase™ DNA Sequencing Kit utilizes the thermostable DNA polymerase of thermus aquaticus (Taq polymerase). There are numerous advantages to sequencing with Taq polymerase.

Reduced Artifacts
The reactions are carried out at 70°C, substantially reducing DNA secondary structure artifacts commonly seen with the Klenow fragment of *E.coli* DNA polymerase, reverse transcriptase, or modified T7 DNA polymerase (Sequenase*).

Specific Primer Binding
The higher temperature also creates more stringent conditions for primer binding. Thus false priming is far less likely to occur at sites of imperfect hybridization.

The ThermalBase™ Sequencing Kit protocol is as simple as sequencing with the Klenow fragment or Sequenase*. Uniform labeling can be achieved with ^{32}P or ^{35}S nucleotides or oligonucleotide primers (including ^{32}P, ^{35}S, or fluorescent primers for automated systems). Single stranded or double stranded (boiling miniprep) DNA templates may be used.

*Sequenase is a trademark of United States Biochemical Corp.

Dr. Maryann Zounes of Syntro Corporation has independently compared Stratagene's Taq Polymerase with Sequenase* (modified T7 DNA polymerase) and a competitor's Taq polymerase. Double stranded supercoiled DNA was prepared using the boiling miniprep procedure. Sequenase* reactions were performed according to the manufacturer's instructions.

Arrows highlight Sequencing artifacts.

Reader Service No.433

The accompanying figure illustrates the ability of Stratagene's Taq polymerase to sequence a double stranded DNA region in which Sequenase* and a competitor's Taq polymerase generate multiple artifact (arrows). Stratagene's Taq polymer proceeds through these regions with little difficulty. Overall, Taq polymerase provides substantially more information in artifact-prone regions than either the Klenow fragment or Sequenase*.

Now you can perform Southern and Northern blot membrane crosslinking with superior results in 30 seconds instead of 2 hours. What are you waiting for?

Introducing the **Stratalinker 1800** from Stratagene.

Vacuum oven baking for 2 hours is now within the domain of molecular biology historians. The UV Stratalinker 1800 is specifically designed to crosslink DNA or RNA to nitrocellulose, Stratagene's Duralon-UV™ nylon, or Duralose-UV™ nylon-reinforced nitrocellulose membranes in approximately 30 seconds, in contrast to the traditional method of baking filters at 80°C for two hours.

The degree of ultraviolet crosslinking can dramatically affect the binding and sensitivity of nucleic acid hybridization (see accompanying graph). Standard UV hoods and light boxes suffer from continual shifts in output making calibration difficult. Stratagene's UV Stratalinker, however, has an internal photo detector. When the appropriate UV energy dose has been achieved, the Stratalinker automatically deactivates its ultraviolet source. The operator need not be concerned with timing the reaction, since the Stratalinker's ultraviolet energy integrator compensates for aging bulbs and power fluctuations. The versatile UV Stratalinker can be used for the following applications:

Introducing Stratagene's New 1989 Catalog

Contains detailed information on the latest products and services for all your molecular biology needs.

Stratagene's 1989 Catalog Features:

- **Stratalinker™**: Crosslink DNA and RNA to nitrocellulose or nylon membranes in just 30 seconds.
- **ThermalBase™ Kit**: DNA sequencing using Taq Polymerase I. Successful sequencing through G-C rich regions.
- **Custom Libraries**: > 10^6 primary plaques in 2-3 weeks. Also available: large assortment of premade cDNA and genomic libraries prepared by Stratagene.
- **Zap™cDNA Synthesis Kit**: High efficiency Uni-directional Cloning.
- **VAGE™ System**: Southern and Northern gels and blotting in 3 hours instead of 30.
- **Lambda Zap™ II**: Lambda phage to pBluescript II without subcloning. Enhanced color selection.
- **Gigapack™ Gold**: Highest commercially available packaging extract. Greater than 2 x 10^9 plaques/ug.
- **Epicurean™ Coli**: High efficiency competent E. coli. (> 10^9/ug)
- **Restriction & Modifying Enzymes**: Very large selection.
- **Next Day Delivery**: Available on U.S. orders until 6PM EST.
- **Technical Support:** Provided by experienced scientists.

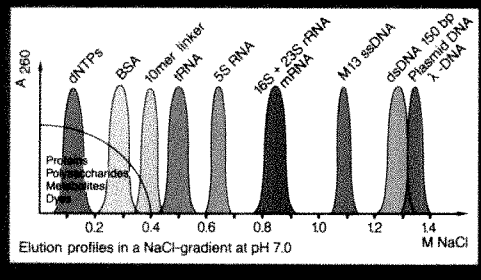
Preparing DNA?

QIAGEN



gle step purification

EN disposables transform cumbersome nucleic acid preparations into an easy, saving and inexpensive job. Picogram to ram amounts of plasmid DNA, λ-DNA, mic DNA or RNA can be directly isolated urified from cleared cell lysates in one due to QIAGENs extended separation e (see fig.).

EN-tips and -packs, which fit on conven- l pipettes or syringes, contain an anion- ange resin, patented to DIAGEN, for solid e extraction of nucleic acids. Expensive pment such as ultracentrifuges, HPLC/ C™ or reagents like CsCl and phenol are no r required.

high purity, excellent yields and superior gical activity of nucleic acids are routinely ved in 10 minutes:

Adsorb the lysate to QIAGEN.
Wash away impurities.
Elute the desired nucleic acid.

Elution profiles in a NaCl-gradient at pH 7.0

Biological activity

The quality of QIAGEN purified nucleic acids has been tested with more than 50 different restriction endonucleases, several polymerases, DNA ligases, phosphatases, kinases, and reverse transcriptases. Outstanding efficiency was obtained in all cases.

tips

QIAGEN-tip 5 and QIAGEN-tip 20 are prepacked pipette tips, with a capacity of 5 and 20 µg of nucleic acids respectively which fit on variable volume pipettes. The entire procedure is performed simply by pipetting the appropriate solution in and out.

packs

QIAGEN-pack 100 and QIAGEN-pack 500 are small cartridges which fit on disposable syringes. The binding capacities are 100 and 500 µg of nucleic acids respectively.

tubes

QIAGEN-tube 20 is an Eppendorf™ tube containing resin sufficient to adsorb 20 µg of high molecular weight genomic DNA (50-200 kb) in a simple and gentle batch procedure.

For free samples and application protocols contact DIAGEN.

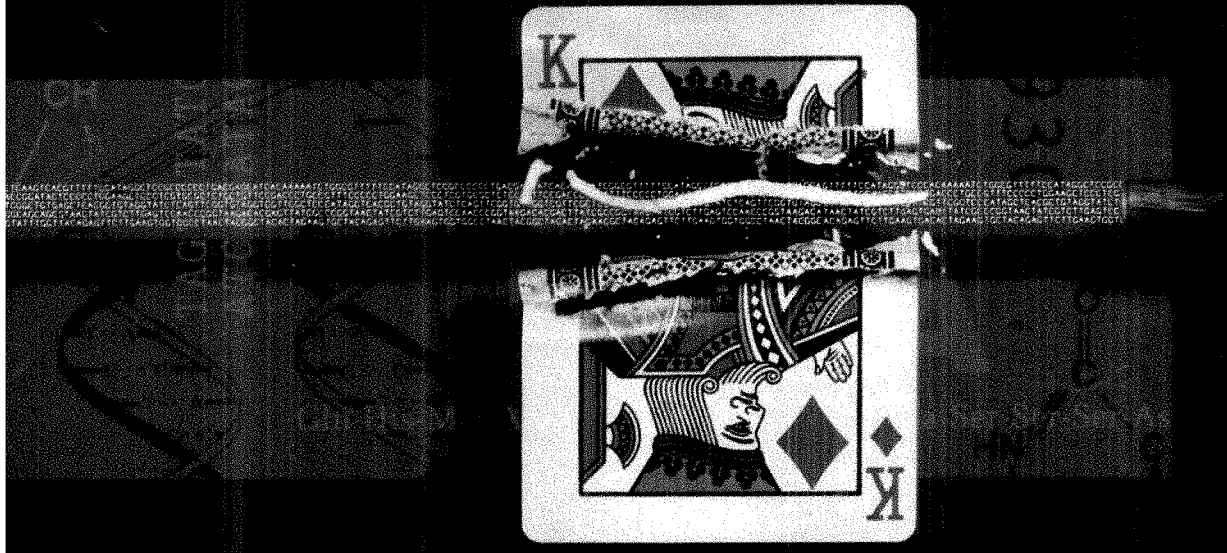
Reader Service No. 193

THE NUMBER 1 REASON TO CHOOSE THE ACUGEN™ PERSONAL DNA SEQUENCER™

#1. EASY TO USE:

Forget autoradiography. Forget reading autoradiograms. Sensitive beta detectors gather data from the gel as it's running and convert that data to DNA sequence. And the gel system is fast, accurate, and easier than any you've ever used.

#1. AFFORDABLE:



The Acugen 402 costs less than half as much as other sequencers. So even if you're a small lab, you can afford it. And if you're a larger lab, you'll probably want to keep several running. The Acugen 402 is a personal sequencer—at a personal price.

#1. ^{32}P DETECTION:

The Acugen 402 builds on success—the success of reliable, inexpensive ^{32}P reagents and standardized, widely used protocols. There are no new complicated techniques to master. All you'll have to get used to, is how fast you can generate DNA sequencing data.

#1. COMPACT:

The Acugen 402 takes up remarkably little bench space—about as much as a manual sequencing apparatus. Yet it brings you all the power of DNA sequencing automation. Big features. Small size. The Acugen 402 is the ultimate combination.

For more information or a complete in-lab demonstration of the Acugen 402 personal sequencer, call us at 1-508-650-1180. We'll show you why we're one up on every other sequencer.

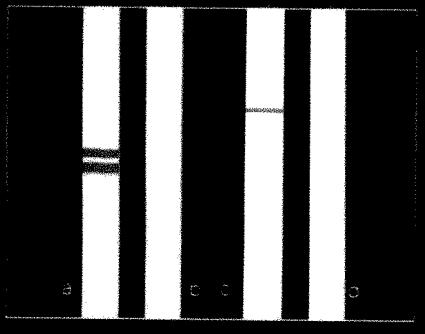
The unique ultra-small immunogold probe for increased labelling efficiency and penetration power

AuroProbe™ One

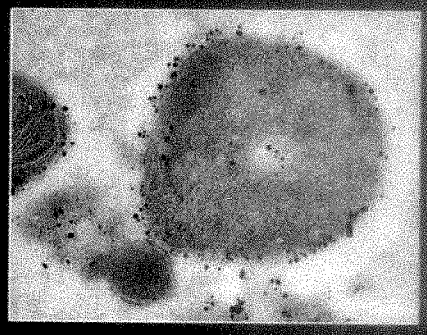


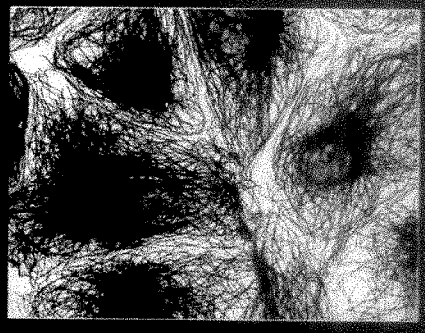
WHY USE AN ULTRA-SMALL GOLD PROBE IN YOUR RESEARCH?

Janssen research developed the **AuroProbe One** technology around colloidal gold particles approximating 1 nm*.
AuroProbe One penetrates tissues and binds to target antigens with higher efficiency than conventional, larger immunogold probes.
That penetration power and labelling density improves immunodetection, whether you are immunostaining tissue or probing for antigen on blots. The **IntenSE**** silver enhancer, required for visualization, uses the relatively larger number of gold nuclei to yield a stronger signal.
Signal-to-noise ratios are markedly improved, and endogenous tissue reactions are absent. You won't need separate AuroProbe One reagents for microscopy and blotting applications as the ultra-small gold probe is an all-round marker system.
Order now! Witness the power and efficiency of AuroProbe One for your research.

* Patent pending ** Trademark

← *In situ* hybridization of cytomegalovirus (CMV)-infected adrenal gland using biotinylated entire CMV genome, rabbit anti-biotin, AuroProbe One and IntenSE. (Volkers, van den Brink & Houthoff, Amsterdam)





← Blot of total extract of Hela cells and blot of partially purified nuclei of rat liver reacted respectively with rabbit anti-tubulin (a) and rabbit anti-actin (c) followed by AuroProbe One and IntenSE. Negative controls (b, d).

Cryosectioned synaptosomes reacted with rabbit anti-B50, AuroProbe One and IntenSE. (van Lookeren-Campagne & van Bergen en Henegouwen, Utrecht) →

PtK$_2$ cells reacted with rabbit anti-tubulin, AuroProbe One and IntenSE →

Vol. 337 Issue no. 6205

The winter solstice Sun shining through the 'roof-box' of the Neolithic passage graves at Newgrange, Ireland, illuminating the main chamber. When the monument was constructed, 5,000 years ago, it may have been used to trace the path of the Sun during the solstice sunrise. See page 343. Cover photo: Claire O'Kelly.

THIS WEEK

Law inaction

Recent judgements in the British courts raise doubts about whether established patents law can cope with new products made by recombinant DNA technology. The antithrombosis agent tissue plasminogen activator is the case in point. Page 317.

Electrons in charge

The discovery of a new family of superconducting copper oxides in which the carriers of the supercurrent are electrons — rather than electron vacancies or 'holes' — has important implications for theories of high-temperature superconductivity, pages 345 and 306.

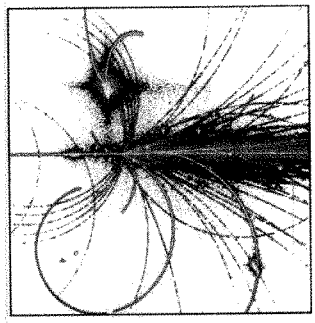
New antibiotics?

A synthetic peptide, modelled on the reactive centre of a human cysteine proteinase inhibitor, effectively blocks the growth of group A streptococcal strains, page 385.

Fossil nebula

The temperature of the massive central star in nebula N44C in the Large Magellanic Cloud is far too low to account for the high excitation emission from the surrounding gas. Is the nebula an 'extinct' luminous X-ray binary? See page 337.

Spadetail mutant



A newly discovered mutant zebrafish should be invaluable in studies of embryo development. An abnormality of mesodermal cell migration changes the position and with it the fate of the cells that normally form trunk somites, page 358.

Before green plants

Are prochlorophytes related to a prokaryotic ancestor of chloroplasts? Sequences of the gene for a component of photosystem II support this phylogeny, but those of 16S rRNAs do not. Pages 380, 382 and 304.

Nuclear matters

The behaviour of dense nuclear matter, whether in heavy atomic nuclei, inside neutron stars or during the early moments of the

Universe, may soon be better understood. Review Article, page 319.

Hard times

Cubic boron nitride — second only to diamond in hardness — has been studied at high pressure using three different methods that show remarkable agreement, page 349.

DNA from RNA

The essential RNA component of the telomerase that synthesizes the telomeric repeats of *Tetrahymena* chromosomes contains the complement of the repeats and thus acts as an RNA template for DNA synthesis, pages 331 and 303.

Guide to Authors

See page 386.

Nature® (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Magazines Ltd (4 Little Essex Street, London WC2R 3LF). Annual subscription for USA and Canada US$275 (institutional/corporate), US$125 (individual making personal payment). USA and Canadian orders to: *Nature*, Subscription Dept, PO Box 7663, Teaneck, NJ 07666-9857, USA. Other orders to *Nature*, Brunel Road, Basingstoke, Hants RG21 2XS, UK. Second class postage paid at New York, NY 10012 and additional mailing offices. Authorization to photocopy material for internal or personal use, or internal or personal use of specific clients, is granted by *Nature* to libraries and others registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided the base fee of $1.00 a copy plus $0.10 a page is paid direct to CCC, 21 Congress Street, Salem, MA 01970, USA. It always helps to get an early warning

TK-REA is a diagnostic method based on one of the body's own warning substances - Thymidine Kinase.

Thymidine Kinase, an enzyme involved in DNA synthesis, is only significant in dividing cells. Serum Thymidine Kinase levels give valuable prognostic information and reflect effectiveness of treatment in haematological malignancies.*

*) NON-HODGKIN'S LYMPHOMA
LEUKAEMIAS

The illustration depicts smoke signals, a form of communication among many native peoples, especially in the North American Indian culture.

Smoke signals were created by burning damp wood and varying the length of each smoke puff in a type of simplified morse code.

Smoke signals had an important function as an early warning of danger.

Prolifigen® TK-REA is the method for serum Thymidine Kinase determination.

Genetic Technology Grade™

Performance Certified

Genetic Technology Grade™ agarose from FMC BioProducts is in a class by itself, having been specifically developed for use in molecular biology procedures. FMC BioProducts is committed to your research.

Each and every Genetic Technology Grade product lot is tested extensively in genetic research laboratories just like yours. We're so confident that these products will perform to your expectations that we certify their applicability for a wide range of electrophoresis procedures. For example, **InCert™ agarose** is certified for enzymatic digestion of chromosomal DNA entrapped within gel plugs. **NuSieve® GTG agarose** is a unique low-gelling/melting temperature formula for fine resolu of DNA fragments below 1,000 bp an quality asssured for direct ligation and transformation of the DNA fragments in th remelted agarose. **SeaKem® GTG agarose**, fine resolution of DNA fragments greater tha 1,000 bp, is extensively tested to ensure the recovery of biologically active DNA.

We provide a technical support hotline so tha you can communicate directly with research scientists who speak your language and understand your needs. Please call **1-800-521-0390**.

Break away from manual routines. We've automated RNA extraction.

Applied Biosystems has announced a new breakthrough—automated purification of RNA with the Model 340A Nucleic Acid Extractor. With new chemistry, the instrument isolates high-quality, total cellular RNA. And it minimizes potential contamination by nucleases.

For more information on how to contact one of our eight worldwide subsidiaries, give us a call. We'd like to help you break into automated RNA and DNA extraction.

Islet-Activating Protein
—Pertussis Toxin—

Pertussis toxin potentiates any reponses of insulin-release from pancreatic islets of mammals and has various other activities such as:

- Promotion of lipolysis on adipocytes
- Inhibition of epinephrine-induced hyperglycemia
- ADP-ribosylation of cell-membrance protein
- Activation of adenylate cyclase
- Lymphocytosis-promoting activity
- Histamine-sensitizing activity
- Hemmagglutination activity
- Adjuvant activity

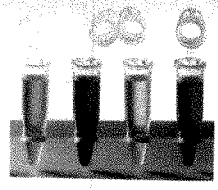
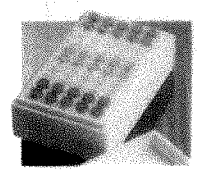
PHOSPHATIDYLINOSITOL (PI)-SPECIFIC PHOSPHOLIPASE C -A NEW POWERFUL TOOL FOR MEMBRANE RESEARCH

Professor Hiroh Ikezawa of Nagoya City University, a founder of PI-anchoring protein, now presents a splendid tool to biochemists, immunologists and membranologists.

"THE PHOSPHATIDYLINOSITOL (PI)-SPECIFIC PHOSPHOLIPASE C"





Sapporo Breweries Co., Ltd. prepares and Funakoshi Pharmaceutical Co., Ltd. distributes exclusively this enzyme from *Bacillus thuringiensis*, in response to the requests of users. Indeed, PI-specific phospholipase C will solve many problems on the presence, structure and biosynthesis of PI-anchoring proteins such as alkaline phosphatase, Thy-1, acetylcholine esterase and so on.

ISI® Institute for Scientific Information®
THE Genuine Article

No Substitute.

It took the original *Current Contents*® company to come up with a weekly electronic journal awareness system this complete.

The new **J-1200 Edition** contains the contents pages from more than 1200 of the leading journals in the life sciences—by far the most comprehensive coverage available on diskette. Even the newly expanded **J-600 Edition** (our "selective" coverage edition) includes hundreds more journals than similar products.

But the story doesn't end with superior coverage.

There's no substitute

...for the unsurpassed degree of control you get with *Current Contents on Diskette*. With the contents pages displayed right on your screen, you can run high-speed scans or just browse along electronically at any pace you like. Nor is there any substitute for the versatility and flexibility that enables you to:

- Create custom search profiles, using key terms, authors, and institutional names — in any combination.
- Examine search hits in context, picking up relevant articles on the contents page.
- Print out or export references, contents pages, and search results to your personal database — simply by clicking a mouse or touching a key.
- Export information in a variety of formats — Dialog, Medline, or comma-delimited.

And thanks to a highly developed user interface, with helpful features such as pull-down menus and pop-up dialog windows, you'll perform these operations rapidly, intuitively.

There's no competition

...when it comes to absolutely automatic reprints. *Current Contents on Diskette* fills in the reprint author's name, your name and address, and the complete reference. Right on special ISI *Request-A-Print*® forms.

Only *Current Contents on Diskette* lets you generate and print orders automatically for *The Genuine Article*®, ISI's 48-hour (or faster) document delivery service.

And (more bad news for would-be competitors), ***only*** ISI offers an option to supplement your diskette subscription with the print version of *Current Contents/Life Sciences*. You receive a considerable discount and the best of both worlds. The portability of print and the power of a PC!

We fit your system...

The IBM PC and 100% compatibles version comes with retrieval software designed by ISI and is available in 5 1/4" and 3 1/2" disk formats. A hard disk and 512K RAM are required (640K recommended).

The Macintosh version runs on MAC Plus, SE, and II—it requires a hard disk drive and HyperCard.

Although both versions contain identical information, each is unique. ISI's indexing technology makes the IBM fast. Very fast. While the Mac version has been engineered to take full advantage of HyperCard and Macintosh's graphic capabilities.

...We fit your needs

Choose from the following subscription plans.

J-600	**$380*/yr**
J-600 + Life Sciences print edition	**$550*/yr**
J-1200	**$725*/yr**
J-1200 + Life Sciences print edition	**$895*/yr**

***Includes shipping to U.S. Slightly higher elsewhere.**

(The combination plans save you more than $150 per year!)

To enter your subscription or to request more information, call **800-523-1850** or **215-386-0100, extension 1483**. Or write us at an address below.

The ***real*** thing says *Current Contents* on the box. Accept no substitutes.

Picture This..

Use Hoefer Software to Get the Most Out of Your Densitometer and Computer.

With Hoefer's Densitometry Software for Scan Storage and Analysis, your densitometer and your IBM PC-compatible or Macintosh computer, you can perform highly sophisticated scan analyses in just seconds. Hoefer's Densitometry Software will:

• Adjust baselines, smooth curves, expand scans • Display up to three windows for comparing scans directly or subtracting one scan from another or aligning separate peaks • Superimpose one set of data on another • Number peaks manually or automatically • Perform simple integration for widely- spaced peaks or Gaussian fit for complex scans • Calculate R_fs of peaks and determine molecular weights using up to 30 knowns and unknowns • Use macro subroutines for unattended repeat data processing • And much, much more! And if you need a densitometer, ask about Hoefer's economical GS 300 Scanning Densitometer.

*The GS 365 program requires an IBM PC or fully compatible computer with a graphics card and 640 K RAM or an IBM PS/2. The GS 370 program requires a Macintosh Plus, Macintosh SE or Macintosh II. Free demonstration diskettes are available on request.

POINT OF FACT

GIBCO's reputation as a major supplier of cell culture products to the Bioprocessing industry is based on a number of facts which differentiate us from competitors and provide us with what we believe to be the most advanced cell biology production plant in Europe.

- All Cell Biology products manufactured according to G.M.P.
- Raw materials pre-tested prior to acceptance.
- Ultrafiltration of all standard single strength media to ensure low endotoxin level.
- Control of all operations fully computerised.
- Quality Assurance checks ensure compliance with Standard Operating Procedures.
- Stringent Quality Control testing with sampling procedures based on the guidelines specified by Military Standard 105D.
- Bulk packaging available to suit customers' requirements.
- Vendor Audits welcomed.

If you are involved in the Bioprocessing Industry and would like to receive the full facts about GIBCO, please contact your local GIBCO Company or Distributor for a copy of our fact-finding Bioprocessing brochure.

Reproducible chromatography is a snap with Bio-Rad prefilled columns

Bio-Rad Econo-Pac® and Poly-Prep® prefilled columns feature:

- Rigorous quality control for reproducibility.
- Econo-Pac columns have upper frits to prevent columns from running dry.
- Detailed protocols for optimal chromatography.
- Snap-off tips for convenience.
- Graduated volume markings for column calibration at a glance.
- 2-10 ml bed volumes.
- Leak-proof closures

Applications include:

- Purification of monoclonal antibodies, even mouse IgG_1, using Bio-Rad's patented buffers* (Protein A column)
- Fast and efficient purification of polyclonal IgG from serum. (Serum column)
- Desalting of samples up to 3 ml in 6 minutes. (10DG column)
- Deionization of formamide, glyoxal, water, or other nonionic solution. (Deionization column)
- Removal of detergents from proteins. (11 A8 and SM-2 columns)
- Anion and cation concentration and removal.
- Heavy metal concentration or removal.

Custom prefilled columns may be ordered to fit your specific application. Both Econo-Pac and Poly-Prep columns are available empty.

After you've had your fill of filling your own columns, give us a try. For details call your local Bio-Rad representative or contact us directly.

*U.S. patent No. 4,704,366.

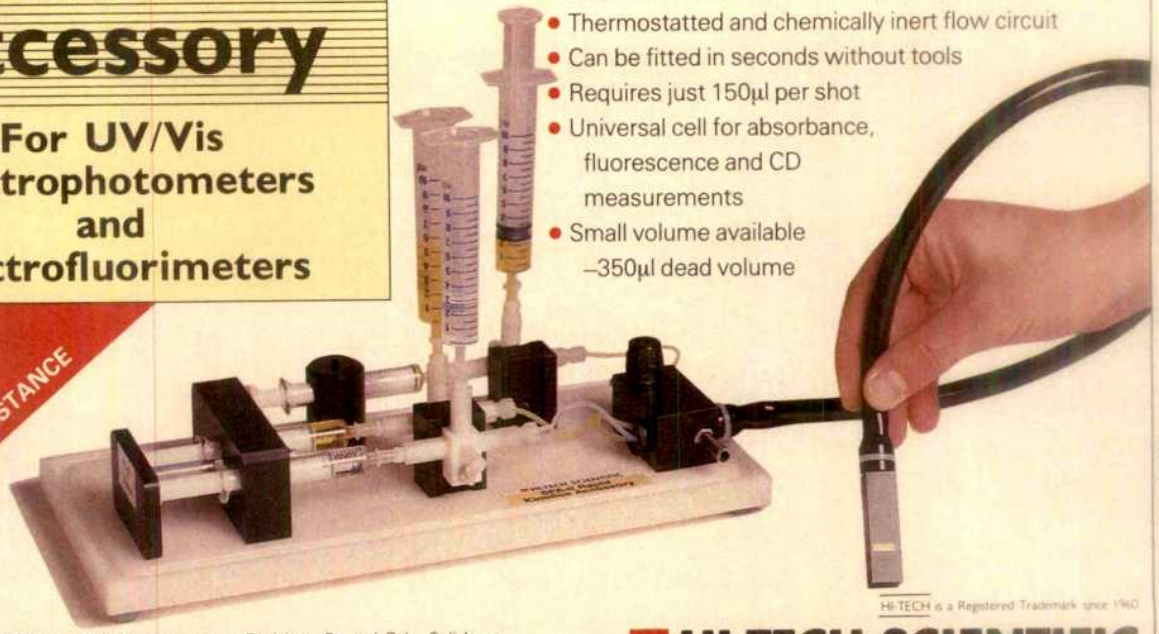
It's the Chemistry that Counts.™



SFA-II Rapid Kinetics Accessory

For UV/Vis Spectrophotometers and Spectrofluorimeters

NEW FEATURES
ENHANCED
CHEMICAL RESISTANCE

Over 300 of these popular units have been sold throughout the world. The SFA-II uses the stopped-flow method to reduce the fastest half life measurable from several minutes to well under a second.

- Observed reaction mixture is just 10cms old
- Thermostatted and chemically inert flow circuit
- Can be fitted in seconds without tools
- Requires just 150µl per shot
- Universal cell for absorbance, fluorescence and CD measurements
- Small volume available –350µl dead volume

HI-TECH is a Registered Trademark since 1960

Stopped and Quenched Flow

Hi-Tech Scientific manufacture the world's most successful and capable rapid kinetic instruments.

- Stringently economical with precious samples
- Empirical dead time of 600 microseconds
- Reaction rates in excess of $2000s^{-1}$ can be routinely followed
- SpectraScan accessory is fast (90nm/ms) and sensitive
- Professional data acquisition and processing software

NEW

- Options for IBM, IBM compatible, Hewlett Packard and Apple
- Excellent fluorescence performance

PCR
Those Oncogenes!

CLONTECH offers the first easy alternative to tedious transfection assays for oncogene research screening. Our products incorporate the GeneAmp† Polymerase Chain Reaction (PCR) process for oncogene amplification, and are optimized for use with the Perkin-Elmer Cetus DNA Thermal Cycler.

The ONCO-LYZER™ Core Kit

Contains the new recombinant Perkin-Elmer Cetus AmpliTaq† DNA polymerase, buffers, dNTPs and control oncogene primers and template —in a package sufficient for 50 amplification reactions. Pair the ONCO-LYZER Core Kit with any of our . . .

PRI-Mate™ Matched Oncogene Primers

Primers are now available for amplifying regions containing codons 12, 13 and 61 of:

• Ha-*ras* • Ki-*ras* • N-*ras*

Each PRI-Mate set comes with instructions for optimized PCR conditions using the ONCO-LYZER Core Kit.

***ras* Oncogene Probes**

We offer MUTA-LYZER™ *ras* oncogene probe panels —the economical alternative to synthesizing the probes yourself. These probe panels can be used to differentiate all point mutations at codons 12, 13 and 61 in the three *ras* oncogenes. Detailed hybridization protocols are included.

All products are for research use only.

†PCR (Polymerase Chain Reaction) is covered by U.S. Patent No. 4,683,202 issued to Cetus Corporation, licensed by CLONTECH Laboratories Inc., for certain research applications only. Patents pending on *Taq* Polymerase and its use. Patents in Europe and Japan applied for. GeneAmp and AmpliTaq are trademarks of Cetus Corporation. ONCO-LYZER, PRI-Mate and MUTA-LYZER are trademarks of CLONTECH Laboratories, Inc.

See Things You've Never Seen Before.

SDS PAGE gel of BSA, ovalbumin, carbonic anhydrase, and phosphorylase b visualized with Coomassie Blue.

HRDI image of the same sample.

High Resolution Dynamic Imaging (HRDI) comes to electrophoresis.

On the left is a conventional SDS Page gel stained with Coomassie Blue. On the right, is the same sample run on Molecular Dynamics HRDI System.

The difference is easy to see — in more ways than one.

HRDI produces phase-contrast images of the same bands without loss of resolution due to post-run diffusion or "stain bleed." There is no fluorescent dye. No radioactivity. No staining. No washing...No waiting.

With HRDI, results are instantaneous. You can actually watch the separation progress. Record results on film or instant prints. Rapidly determine compound purity for protein sequencing. Take several exposures of the same gel for optimal separation. Digitize the image.

All without removing the glass plate from the gel!

HRDI even lets you analyze small peptides without sample loss and quantify compounds that are difficult or impossible to stain. And since your compounds are not exposed to dyes, acid, or radioactivity, they remain unmodified for sequencing or activity measurements.

Electrophoresis will never be the same.

Start seeing things. Call or write for our free brochure, *High Resolution Dynamic Imaging for Visualization of Electrophoresis Gels.* And take full advantage of the power of electrophoresis.

LIVING PROOF:

ANALYSING SUB-CELLULAR Ca^{2+} & pH CALLS FOR MAGICAL

MAGICAL is a complete system for analysing the spatial and temporal variations of Ca^{2+}, pH and other ions in living cells.

The system captures, ratios and measures digital sequences of fluorescent images and has been developed by established image analysis specialists in conjunction with cell biologists in both the UK and the USA and in collaboration with Dr. Eric Gruenstein, Director of the Image Analysis Centre, University of Cincinnati Medical School.

The fluorochromes Fura-2 and Indo-1 may be used to measure Ca^{2+}, and DCH and BCECF to monitor pH. The facility to alternate between excitation or emission filters, depending on the dye, is provided by an electronic filter changer and the system also allows a choice of types of inverted microscopes and intensifying cameras to be used.

Images are captured with user selectable resolutions from 64 x 64 pixels up to 512 x 512 spatially, 64 or 256 grey levels and at intervals from 0.08 seconds to several hours. A dedicated image processing and analysis system performs fast ratioing of sequences of images. Successive video frames may be averaged and integrated and background fluorescence may be corrected.

MAGICAL provides 2, 8 or 32 M Bytes of fast image memory capacity, with all the permanent storage options available for PC/AT compatible systems. The associated software provides a wide range of facilities, including graphical analysis, 3D presentations, montages of selected frames from any sequences for comparison and for publishing results.

Menus on a separate screen from the cell images make MAGICAL easy to use, via keyboard, mouse or light-pen.

Outlining cell boundaries and zooming in, user-calibration of ion concentrations, pseudo-colouring by light-pen from a palette, and variable-speed animation are all parts of the complete visual and quantitative research tool-kit provided by MAGICAL.

LEADING · THE · WAY · IN · THE · SCIENCE · OF · ANALYSIS

MicroSelect. Basics for Biochemistry

«MicroSelect», a new label for high quality products for use in biochemistry. Based on the fact that basics used for biochemistry are usually present in large quantities compared to the substances under investigation they require an exceptionally high purity. Researchers in the field of life sciences therefore ask for top quality products they can rely on. Fluka basics for biochemistry have been specially developed for applications in biological and biochemical reactions.

The Fluka MicroSelect quality label guarantees:
- a homogeneous appearance (form and color)
- a homogeneous and clear appearance in solution (solubility test)
- zero residue in the filter test
- limited UV absorbance at biochemically relevant wavelengths
- a pH value of an aqueous solution within a defined range

The MicroSelect programme includes
- ammonium, calcium, cesium, lithium, magnesium, potassium and sodium salts
- biological buffers, buffer components and standard buffer substances
- precipitation and denaturation reagents
- chelators and complexing agents
- antioxidants
- density gradient centrifugation chemicals
- amino acids

Ask for your free copy of the Fluka MicroSelect brochure.

NEW JOURNAL!

GENES CHROMOSOMES & CANCER

Editors-in-Chief

Felix Mitelman
Professor and Chairman • Department of Clinical Genetics
University Hospital • University of Lund
Lund, Sweden

Janet D. Rowley
Professor of Medicine • Joint Section of Hematology/Oncology
The University of Chicago Medical Center
The Pritzker School of Medicine • Chicago, Illinois

Significant advances are being made in the cytogenetic and molecular genetic characterization of benign and malignant neoplastic cells. Tumor-specific chromosomal changes identify the locations of genes critical to malignant transformation. Molecular analyses of these genes or DNA sequences provide a more detailed understanding of their structure and function in both normal and neoplastic cells. Tumor-associated chromosomal and DNA alterations serve as increasingly important diagnostic and prognostic markers. Efforts to identify genes that determine inherited susceptibility to cancer are progressively more successful.

In recognition of the interaction among these different aspects of oncogenetics, and to foster improved communication among basic research scientists and medical oncologists, we are pleased to announce the establishment of a new primary research journal: **GENES, CHROMOSOMES & CANCER.**

Genes, Chromosomes & Cancer will offer rapid publication of original full-length research papers, short communications, concise invited reviews, as well as editorial commentaries on all aspects of genomic abnormalities related to neoplasia. Particular emphasis will be placed on work combining molecular and cytogenetic analyses of the acquired genetic alterations of cancer cells. While preference will be given to research utilizing analytical approaches, descriptive studies and case reports will also be welcomed, particularly when they offer insights regarding basic biologic mechanisms or the clinical management of neoplastic disorders.

Specific areas covered will include:

- chromosomal abnormalities in all benign and malignant disorders, including changes that occur during neoplastic progression
- changes in gene structure and regulation as a consequence of genomic rearrangements
- chromosomal alterations involving oncogenes, anti-oncogenes, and other genes related to the regulation of cell proliferation and differentiation
- the correlation between genomic abnormalities and cellular phenotypic alterations (e.g.: gene amplification and multidrug resistance, histopathological markers, antigenic changes, abnormal cell differentiation or proliferation)
- the predictive value of alterations at the chromosomal and DNA levels in disease prognosis, and in designing and monitoring cancer therapies
- cytogenetic, molecular, and epidemiologic analyses of inherited (familial) disorders predisposing to cancer
- chromosomal and/or genetic damage caused by external factors
- descriptions of novel molecular biological and cytogenetic methods for genomic analysis

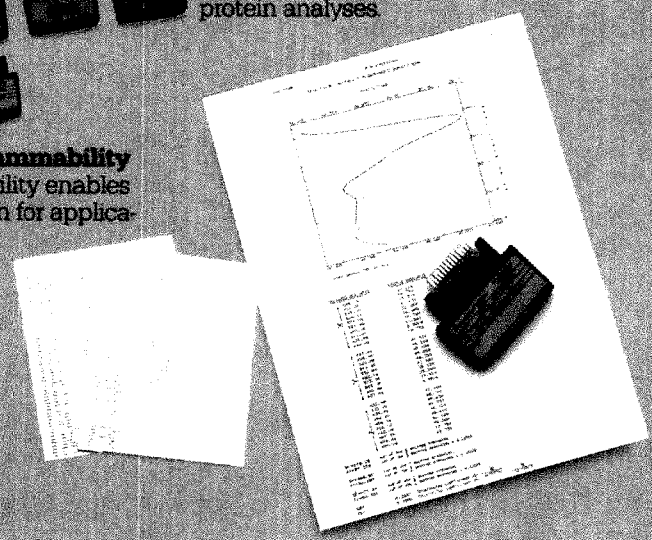
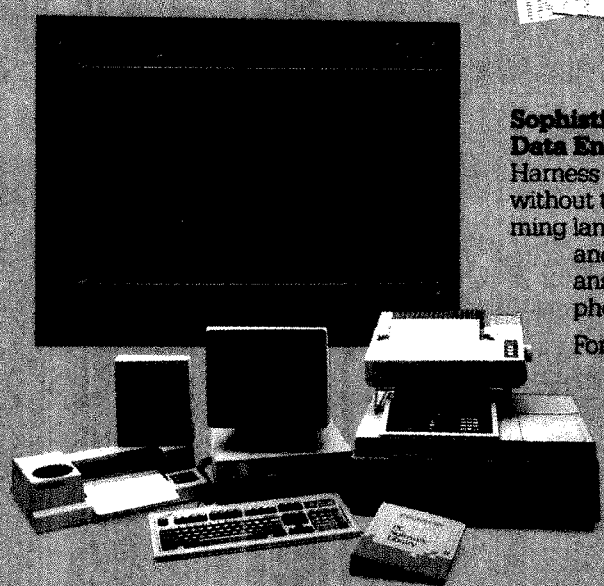
The Simple Solution
FOR YOUR DATA HANDLING NEEDS



Only Beckman offers you a choice of flexible control and computation software designed to save you time while ensuring accurate, reliable final answers time after time.



Convenient On-line Preprogrammed Software

Easy to use Beckman Soft-Pac™ program modules control sample delivery and data acquisition as well as plot and format data output. Especially useful in qualitative and quantitative analysis, kinetics, gel scanning, molecular weight determination, nucleic acid and protein analyses.

Customized Programmability

A built-in "step programming" capability enables you to customize instrument operation for applications not included on a Soft-Pac. You customize sample delivery, data manipulation and data formats. Then, just press a button for final results.

Sophisticated Off-Line Data Enhancement

Harness the power of your personal computer** without the need to learn a complicated programming language. Beckman DU® Data Leader™ and DU® Data Capture™ are powerful, answer-oriented software tools for spectrophotometer control, data storage and analysis.

For more information on how to make your data analysis simpler, more efficient, contact: your local Beckman sales representative or call toll free 1-800-742-2345.

Epitope Scanning & Mimotope Design Kits from Cambridge

Cambridge Research Biochemicals, under licence* from the Commonwealth Serum Laboratories, is offering a unique Multi-Pin Synthesis Technology which allows the concurrent synthesis and screening of hundreds of peptides in only a few days. Now any scientist can produce almost limitless numbers of novel peptides for immunological evaluation using ELISA-based systems.

The Epitope Scanning Kit permits identification of continuous epitopes within a protein antigen. All the possible sequential peptides derived from the protein sequence are synthesised. Peptides reacting with antibody are homologues of protein antigenic determinants.

The Mimotope Design Kit takes this technology one stage further, allowing the construction of novel peptide sequences capable of mimicking the actual epitopes of an antigen. Reactive peptides may have no homology to these epitopes and are therefore termed Mimotopes. Virtually any antigenic determinant may be mimicked by a synthetic peptide Mimotope.

Both Kits are supplied with extensive computer software support, a comprehensive materials and reagents package and a detailed instruction manual.

Contact our Technical Sales Department now for full details.

* EPITOPE SCANNING-INTERNATIONAL PATENT APPLICATION NOS. PCT/AU84/00039 & PCT/AU84/00038
MIMOTOPE DESIGN-INTERNATIONAL PATENT APPLICATION NOS. PCT/AU85/00165 & PCT/AU86/00110

Montage of fresh rat liver sample, cryofixed with the CF 100™ without cryoprotectants, and Molecular Distillation Dried. Sample was vapor phase osmicated prior to embedding in pure Spurr's resin.

From Art... to Science

The LifeCell Process™

- **Cryofixation**
- **Molecular Distillation Drying**

Analytical techniques in electron microscopy place stringent requirements on biological sample preparation. The method of choice often employs cryofixation, which is technically difficult and, until now, very much an art form.

With LifeCell's automated CF 100™, the art of cryofixation has been transformed to a precise science. All critical parameters are optimized and microprocessor controlled, providing unsurpassed quality of preservation and reproducibility.

LifeCell's Molecular Distillation Dryer carries this science even further toward excellence by drying the cryofixed samples at extremely low temperatures and infiltrating them with resin. The standard convenience of room-temperature sectioning is then combined with optimal retention of biochemical and elemental sample components.

The LifeCell Process™ is available in your own lab with LifeCell's CF 100™ and Console Molecular Distillation Dryer or as a contract service through our Processing Centers.

Who Offers The Extra Dimension In Peptide Technology?

Right Choice

Only Bachem has the depth of experience in peptide technology, and the selection of over 2,000 products, to assure your research stays on track.

Bachem's position of leadership has emerged from the two decades we've invested in perfecting our proprietary synthetic and purification techniques. And now this practiced discipline delivers to you unequaled purity, activity and value in every Bachem product. In fact, from synthetic peptides and intermediates to our new recombinant growth factors, we pride ourselves in knowing they are the very best.

But there's an extra dimension. Only Bachem can offer you unsurpassed scale-up capabilities whether you order milligrams or kilograms of research or bulk pharmaceutical grade peptides. Our products consistently set the standard for quality and value regardless of how complex the sequence or how fast you need custom synthesis. And the purity is guaranteed.

Start your working relationship with Bachem by requesting our catalog of peak purity products. Our knowledgeable customer service representatives stand ready to meet your product requirements quickly and efficiently. And if you have any technical questions, or require bulk price quotations we will be glad to help Remember, with all the choices you have left today, Bachem is the right one.

It's the quality that counts

Introducing the Pharmacia LKB RediFrac. The simple, stand-alone fraction collector for Standard Chromatography.

Buying an ordinary low cost fraction collector can be kind to your budget but hard on your results – and your peace of mind. You need to be able to trust the quality of your fraction collector even the most simple. This quality can cost a little more, but always pays in the end.

Why take the risk? Trust the RediFrac, the latest of the top quality fraction collectors from Pharmacia LKB. Every drop collected every time. Always working, always secure, year after year. Count on our quality and buy the best.
Buy RediFrac.

- High quality gives trouble-free collection
- Small and lightweight, goes anywhere you want it
- Simple to use for a fast start to separations
- Safe collection of every drop in every tube
- Tough and resistant against cold, chemicals and humidity
- Essential extras – range of racks, cooling, event mark and pump control

RediFrac – now the best choice for simple fraction collection.

Making it big in the molecular world.

We're one of the world leaders in the synthesis of biomedical research chemicals. We make everything from oligosaccharides & mutagens to glycosidase inhibitors and diagnostics. Both cold and radiolabelled. For everyone from research end users to chemical companies. And what we aren't making we'd be pleased to create on request. We have a reputation for purity and consistency that is second to none. And an equal commitment to new product development. Once you deal with us you'll wonder how you managed without us.

"...a major breakthrough in the field of molecular biology..." —SIM News

"It is having a revolutionary impact."—H.H. Kazazian, Johns Hopkins University

PCR TECHNOLOGY Principles and Applications for DNA Amplification

Edited by Henry Erlich, PhD, Senior Scientist and Director of Human Genetics, Cetus Corporation

PCR (Polymerase Chain Reaction) technology is a revolutionary technique which enables scientists to rapidly generate large amounts of genetic material from a slight trace which would otherwise be too small to analyze. With applications in both research and diagnostics, PCR will soon become a standard procedure in biotechnology and medical diagnostic laboratories. *PCR Technology: Principles and Applications for DNA Amplification* is an introduction and guide to the technology. Written by the pioneers in the field, this is the authoritative publication detailing the methodology and the wide range of applications of PCR technology, including medicine, evolution and forensics.

Projected contents: INTRODUCTION TO THE PCR
History of PCR Development—Brief Essay • Description of the PCR Method—Basic Principles and Properties of the PCR • Thermostable DNA Polymerases • Automation • Sample Preparation
RESEARCH APPLICATIONS—BRIEF OVERVIEW
Direct Sequencing Using PCR • Preparation of Specific DNA Fragments Using PCR • Detection of Gene Expression • Genetic Mapping Using PCR Amplification of Individual Gametes
DIAGNOSTIC APPLICATIONS—BRIEF OVERVIEW
Detection of Pathogens • Diagnosis of Monogenic Genetic Diseases • HLA DNA Typing and Disease Susceptibility • Forensic Applications • Detection of Activated Oncogenes • Future Developments and Applications—Brief Essay

March 1989, approx. 176 pp., softcover 0-935859-56-X $19.95
The first volume in the series: Breakthroughs in Molecular Biology

STOCKTON PRESS

Send orders to **Stockton Press**, 15 East 26 Street, New York, NY 10010. Or call toll free: 1-800-221-2123 (In NY, call 212-481-1334). We accept Visa, MasterCard, Diners Club, and American Express. NEED A MILLION cDNA CLONES?

With Promega's Complete Systems It's As Easy As ...

1 RiboClone™ cDNA Synthesis System

Copies your mRNA into dsDNA
- Efficient full length synthesis of cDNA
- Convenient single tube system

2 RiboClone™ Adaptor Ligation System

Adds adaptors to the ends of your cDNA
- Efficient —minimize loss of valuable cDNA
- Rapid —eliminate methylation and restriction digestion steps
- Easy —remove excess adaptors with spin columns
- Complete—optimized components and detailed protocols

3 A Complete Selection of Advanced Vectors

Offering you the choice of:
- Orientation-Specific Cloning allowing for
  - Construction of Subtraction Libraries
  - Higher Efficiency Expression Libraries
- Simplified Subcloning
- Blue/Clear Screening of Recombinants
- Expression of Cloned Sequences as Fusion Proteins
- Arms Preparations Optimized for
  - Lowest Background
  - Highest Efficiencies

Our complete systems generate as many as 1×10^7 clones/µg of your mRNA. Contact Promega for more information on your specific needs. Call **1-800-356-9526.**

USB RESTRICTION ENZYMES AND A 50% DISCOUNT OFFER.

- **Large Selection**
- **High Concentrations**
- **Free Buffer**
- **Quality Guarantee**

Purchase any restriction enzyme and USB will give you — absolutely free — anything from our General Biochemical or Molecular Biology catalogs that you order at the same time, up to 50% of the dollar value of your restriction enzyme order. *Now, through April 30, 1989.*

United States Biochemical carries a large selection of restriction endonucleases recognizing specific DNA cleavage sites ranging from Aat I to Zan I (we carry the isoschizomer Mva I). In addition, USB offers both low and high concentrations of many restriction enzymes commonly utilized in molecular biology labs. Included with each restriction enzyme is a free tube of restriction enzyme buffer.

Each batch of restriction enzyme is completely analyzed to strict quality control specifications to assure you that the enzymes we provide are of the best possible quality for even the most demanding applications. Restriction enzymes as with all our biochemicals are backed by our quality guarantee.

Just order any restriction enzyme — then choose what you want free from our Molecular Biology Catalog and/or General Biochemical Catalog with over 6,000 listings.

For a free copy of our Molecular Biology or General Biochemical catalogs, write USB at P.O. Box 22400, Cleveland, Ohio 44122. Phone 800/321-9322. From Ohio or Canada, call collect: 216/765-5000. Telex: 980718. FAX: 216/464-5075.

New Journals for 1989 from Pergamon Press

CELLULAR SIGNALLING

Editor-in-Chief: **MILES D HOUSLAY,**
Molecular Pharmacology Group, Institute of Biochemistry, The University of Glasgow, Glasgow G12 8QQ. UK

This journal will publish original papers covering all aspects of mechanisms, actions and structural components of cellular signalling systems. The emphasis will be on the production, regulation, degradation and action of second messengers; the structure, regulation and action of receptors; guanine nucleotide regulatory proteins; effector systems, such as tyrosyl kinases, adenylate and guanylate cyclase and ion channels; the effect of cellular signalling events on the functioning, growth and differentiation of target cells in normal and pathological states and also cellular oncogenes.

Within the scope of the journal, manuscripts dealing with biochemistry, cell biology, molecular biology, pharmacology, neurobiology, molecular endocrinology and molecular oncology will be welcomed. The journal will also publish short original reviews on topical subjects.

Subscription Information
1989: Volume 1 (6 issues)
Annual subscription (1989) DM 465.00
Two-year rate (1989/90) DM 883.50
ISSN: 0898-6568
First two issues published in October and December 1988!

German Mark (DM) prices quoted apply in Europe, Africa, Asia/Australasia (with the exception of Japan).
Prices and proposed publication dates are subject to change without prior notice.

PROGRESS *in* GROWTH FACTOR RESEARCH

Executive Editor: **JOHN K HEATH,**
Department of Biochemistry, University of Oxford, South Parks Road, Oxford OX1 3QU, UK

Associate Editors: **MIKE DEXTER,** *UK,*
ANITA ROBERTS, *USA*
JUDSON J VAN WYK, *USA*
BENGT WESTERMARK, *Sweden*

This journal features timely and authoritative reviews of current research and applications on growth factors and related regulatory peptides. The scope of the journal encompasses the structure and biological properties of growth factors, the structure and function of their receptors and signalling oncogenes, signal transduction pathways and effector systems, and regulation of gene expression.

Progress in Growth Factor Research also aims to cover the role of growth factors in biological processes such as development, tissue repair and regeneration, and reflect advances in therapeutic applications of growth factor research in human and veterinary medicine. The review articles are commissioned from leading researchers and will be of value to all biomedical workers seeking to keep abreast of this rapidly expanding field.

PROTEIN ENGINEERING '89

20 – 25 AUGUST 1989 ● KOBE, JAPAN

Organized by the Protein Engineering Society of Japan, in association with the Protein Engineering Research Institute and the journal *Protein Engineering*, **Protein Engineering '89** aims to give researchers and students in this important field the opportunity to discuss developments since April 1987 when Protein Engineering '87 was held in Oxford, UK. It will also offer possibilities for an international exchange of ideas.

SCIENTIFIC PROGRAMME

PLENARY LECTURES

A. Klug : MRC (U.K.)
S. Numa : Kyoto Univ. (Japan)

INVITED SPEAKERS FOR ORAL SESSIONS (Tentative)

Session I:
THEORETICAL ASPECTS OF PROTEIN

B. Brooks : National Institute of Health (U.S.A.)
M. Go : Kyushu Univ. (Japan)
P.A. Kollman : Univ. of California (U.S.A.)
K. Nishikawa : Kyoto Univ. (Japan)
T. Noguti : Kyushu Univ. (Japan)
W.R. Taylor : National Institute for Medical Research (U.K.)
A. Warshel : Univ. of Southern California (U.S.A.)

Session II:
STRUCTURAL ASPECTS OF PROTEIN

Y. Arata : The Univ. of Tokyo (Japan)
G.M. Clore : National Institute for Diabetes and Digestive and Kidney Diseases (U.S.A.)
R. Huber : Max-Planck Institut für Biochemie (F.R.G.)
F. Inagaki : The Tokyo Metropolitan Institute of Medical Science (Japan)
M. Kainosho : Tokyo Metropolitan Univ. (Japan)
Y. Katsube : Osaka Univ. (Japan)
Y. Kyogoku : Osaka Univ. (Japan)
Y. Mitsui : The Univ. of Tokyo (Japan)
K. Morikawa : Protein Engineering Research Institute (Japan)
G.A. Petsko : MIT (U.S.A.)
G.C.K. Roberts : Univ. of Leicester (U.K.)
G.M. Rosenberg : Univ. of Pittsburgh (U.S.A.)
N. Sakabe : National Laboratory for High Energy Physics (Japan)
K. Tomita : Osaka Univ. (Japan)
P.E. Wright : Research Institute of Scripps Clinic (U.S.A.)
W. Yoshikawa : Protein Engineering Research Institute (Japan)

Session III:
FUNCTIONAL ASPECTS OF PROTEIN

B.F.C. Clark : Aarhus Univ. (Denmark)
M. Futai : Osaka Univ. (Japan)
T. Imoto : Kyushu Univ. (Japan)
E. Ohtsuka : Hokkaido Univ. (Japan)
T. Oshima : Tokyo Institute of Technology (Japan)
K. Miura : The Univ. of Tokyo (Japan)
P. Schimmel : MIT (U.S.A.)
D. Söll : Yale Univ. (U.S.A.)
K. Titani : Fujita-Gakuen Health Univ. Hospital (Japan)
H. Weber : Univ of Zürich (Switzerland)
K. Yutani : Osaka Univ. (Japan)

Session IV:
MEDICAL AND INDUSTRIAL ASPECTS OF PROTEIN

S.J. Benkovic : The Pennsylvania State Univ. (U.S.A.)
T. Beppu : The Univ. of Tokyo (Japan)
F.T. Hong : Wayne State Univ. (U.S.A.)
K. Imai : Osaka Univ. (Japan)
S. Nishimura : National Cancer Center (Japan)
H. Okada : Osaka Univ. (Japan)
A.R. Rees : Univ. of Oxford (U.K.)
G. Winter : MRC (U.K.)

Workshop I:
DATABASE

P. Argos : EMBL (F.R.G.)
N. Go : Kyoto Univ. (Japan)
D.G. George : NBRF (U.S.A.)
M. Kanehisa : Kyoto Univ. (Japan)
J.L. Markley : Univ. of Wisconsin (U.S.A.)
T. Ooi : Kyoto Women's Univ. (Japan)
A. Tsugita : Science Univ. of Tokyo (Japan)

Workshop II:
SECRETION AND TRANSLOCATION OF PROTEIN

K. Ito : Kyoto Univ. (Japan)
M. Kikuchi : Protein Engineering Research Institute (Japan)
S. Mizushima : The Univ. of Tokyo (Japan)
W. Neupert : Univ. München (F.R.G.)
R. Schekman : Univ. of California (U.S.A.)
P. Walter : Univ. of California (U.S.A.)

The New Horizon

Hyatt Regency/University of Miami
James L. Knight International Center
Miami, Florida • February 6–10, 1989

The 21st Miami Winter Symposium is the one conference of 1989 that will prepare researchers (both academic and industrial) for the life-science revolution of the 21st century—the human mind's discovery of itself. Don't miss that opportunity. Don't miss *Advances in Gene Technology: Molecular Neurobiology and Neuropharmacology*.

The Symposium offers an unparalleled program. No other gathering offers so many opportunities with such immediate access to fellow attendees. with this six-fold opportunity:

Advances in Gene Technology: Molecular Neurobiology and Neuropharmacology. Five days of lectures, more than 40 top researchers on the molecular biology of the nervous system.

The Second Annual Neural Systems Symposium: Computer Neural Networks. Two days of seminars on modern thinking on neural systems.

Focus Groups. Posters and extracurricular discussions spotlight key research issues from Alzheimer's disease to nerve-cell culture.

Workshops. Hands-on introductions to the latest research tools and concepts.

Placement Service. Job-seekers and employers will meet to fill positions in academia and industry.

Poster Sessions. A hundred authors on hand to present their most interesting results.

CELL BIOLOGY: INTERNATIONAL REPORTS

Editor **G. BULLOCK**
Pharma Division, Ciba-Geigy, Basel, Switzerland
Deputy Editor **C. HAWES**
Department of Plant Sciences, University of Oxford, U.K.

Cell Biology: International Reports is the official publication of the International Federation for Cell Biology. Supporting the need to produce good papers rapidly, the editors are able to offer plant and animal scientists the opportunity of informing others of their new data within a few weeks, whether as full papers or as short communications. Promoting the aims of most cell biologists, papers relating structure and function, and particularly the use of new techniques, are very welcome. Facilities to publish Abstracts from meetings of constituent societies are provided where possible (i.e. subject to space, timing, etc.). Information on scientific activities such as meetings and courses is published in a regular calendar. An improved book reviewing facility has been recently introduced.

RESEARCH AREAS INCLUDE:
• Cancer research • Cell repair systems • Cellular immunology • Developments in botany • Intra- and intercellular trafficking • Pathology and cell damage •

Publication: Volume 13, 1989, Monthly
Subscription: £110.00(U.K.only)/U.S.$218.00(Overseas)

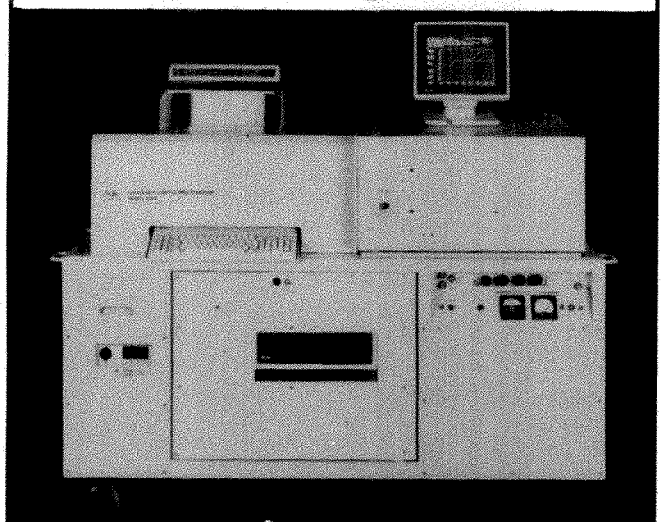
MOLECULAR BIOLOGY & MEDICINE

Editors-in-Chief
J. SAMBROOK *University of Texas, Dallas, U.S.A.*
D. J. WEATHERALL *John Radcliffe Hospital, Headington, Oxford, U.K.*

Molecular Biology & Medicine takes as its main task the publication of original scientific work carried out at the molecular level in areas that are of direct relevance to the causes, prevention, and treatment of human disease.



RESEARCH AREAS INCLUDE:
• Analyzing the molecular mechanisms of pathogenesis in human diseases caused by microorganisms and parasites • Characterizing defects and responses of the immune system associated with human disease • Defining the structure or expression of particular genes involved in specific human diseases • Describing new diagnostic, prophylactic, or therapeutic agents produced by recombinant DNA or hybridoma technology • Presenting new methods for genetic/molecular analysis and diagnosis of common diseases such as diabetes, heart disease, psychiatric disease etc..

Publication: Volume 6, 1989, Bi-Monthly
Subscription: £60.00(U.K.only)/U.S.$100.00(Overseas)
Personal rate £30.00(U.K.only)/U.S.$50.00(Overseas)

Biotechnology Guide U.S.A.

Companies, Data and Analysis

Mark D. Dibner, P.h.D., *Director*
Biotechnology Information Center,
North Carolina Biotechnology Center

Biotechnology Guide U.S.A. is a desktop reference that provides you with specific and detailed information on U.S. biotechnology companies. It focuses on the 360 key firms working directly with the new technologies, and gives details of each company and an analysis of the industry as a whole.

The Guide features listings and rankings, which analyze companies by: financing and equity • revenues • R&D budgets and relative importance • personnel • areas of interest • partnerships • patents • subsidiaries • founding and founders • state.

In addition to the analysis of the 360 core companies, the Guide describes the involvement of large corporations in the biotechnology industry, and offers information on the work of the state biotechnology centers.

Eds **R.M. Anderson and J.M. Thresh**

Many techniques and approaches to the study of epidemiology have been adopted by scientists working in different disciplines. In this book contributions from specialists in plant, animal and human diseases, including AIDS, are brought together, showing how modern techniques are being used to elucidate both new and long-standing problems.

281 pages £55.00 (U.K.) £58.90 (Overseas) ISBN 0 85403 364 5 1988

THE GEOLOGICAL EVOLUTION OF TIBET

The Tibetan Plateau fascinates Earth scientists, who regard it as the type example of collision tectonics: collision between the Indian and Eurasian continents. This book presents the results of a Geotraverse made in 1985 through cooperation between Academia Sinica and the Royal Society. Data from a wide range of geological methods are presented, along with a coloured geological map of the region traversed, and conclusions about the geological evolution of the plateau are given.

INOSITOL LIPIDS AND TRANSMEMBRANE SIGNALLING

Eds **M.J. Berridge and R.H. Michell**

Inositol lipids have become a subject of great interest because of their central role in transmembrane signalling. The Royal Society Discussion Meeting held in December 1987 brought together most of the leading workers in the field. This book contains their written contributions, which deal with all aspects of this ubiquitous signalling system.

200 pages £39.50 (U.K.) £42.00 (Overseas) ISBN 0 85403 358 0 1988

ORGANOMETALLIC CHEMISTRY AND ORGANIC SYNTHESIS

Eds **M.L.H. Green and S.G. Davies**

The selectivities imposed by transition metal templates during organic synthetic transformations has led to the development of an increasing number of synthetically useful reagents and reactions. Recent advances, in and the future prospects for, the applications of stoichiometric and catalytic reactions are presented, with the chemo-, regio- and stereoselective aspects highlighted.

151 pages £30.00 (U.K.) £31.95 (Overseas) ISBN 0 85403 365 3 1988

THE SOLAR SYSTEM: CHEMISTRY AS A KEY TO ITS ORIGIN

Eds **S.K. Runcorn, G. Turner and M.M. Woolfson**

Many lunar and meteorite specimens and the larger planetary bodies have been chemically unmodified since their formation, providing a frozen record of the Solar System's chemistry at its origin. This evidence and its many interpretations are discussed with guidance from eminent scientists renowned for their work in the subject.

153 pages £50.00 (U.K.) £53.00 (Overseas) ISBN 0 85403 360 2 1988

The above casebound books contain collections of papers (all presented at meetings of the Society except for *Tibet*) and were all first published in recent issues of *Philosophical Transactions of the Royal Society*.

Safeguarding British research

Recent improvements of the climate in British research do not imply that the dangers have passed. Indeed, the most serious — complacency — is more serious now than ever.

SURPRISING as it may seem, the morale of the British research enterprise may be on the mend, if only slowly. There are several explanations, not the least of which is that the spate of bad news has abated to a mere trickle. Laboratories are still being closed — a meat research station a few weeks ago, now a couple of veterinary schools (see page 294) — but to those still with posts, the prospect that most institutions would be shrunken images of their present, let alone their past, selves seems to have receded. And there is to be some extra cash. In the financial year that begins in April, the government's direct subvention of basic research will increase by £95 million to a total of £850 million. Indeed, potential recipients of the extra funds might by now have known whether anything extra is likely to come their way if the government's announcement of how the total budget will be allocated between the research councils and other spending agencies, originally planned for earlier this week, had not unaccountably been postponed.

In the circumstances, there is a danger that alarm, itself begotten of complacency, will breed a further round of indifference. At a time when even British high-energy physics has been told (in last week's corporate plan of the Science and Engineering Research Council — see page 296) that there is no "wish to reduce the provisions for nuclear physics further", it may be all too tempting to suppose that the passage of time will mend the damage done to British research in the past decade, in due course even providing a platform for resurgence. But in reality, passivity of that kind will invite only further trouble. If there is now to be a breathing space, the research community should use it as an opportunity for healing wounds and for ensuring that the privations of the past decade will not recur.

It is important, first, to understand what has happened. The mere fact that laboratories have been closed and their members dispersed or put out to grass is in one sense water under the bridge. The process of contraction may have seemed arbitrary at the time, and unjust to many of the people who lost their jobs, but nobody would now recreate the same laboratories even if practical problems since brought to light cannot now as easily be solved. (The agriculture and food ministry's mishandling of the recent and still-current scare about the infection of eggs by Salmonella bacteria might have been avoided if the once-luxuriant agricultural research establishment were still in being.) Similarly, while British researchers may rightly regret the numbers of erstwhile colleagues who have gone for good elsewhere, there is probably no way now of bringing them back.

Damage

The much more serious and lasting damage is that done in people's minds. And even if researchers may now believe that there are smooth waters ahead, the minds of others will retain the impression of a research profession under threat for a long time to come. That this must be so is shown by the still laggard recruitment of young people to science courses at universities and polytechnics, and by the shortage of graduates clamouring for careers in research.

That is why the British research enterprise must from now on pay more attention to its public reputation, especially among young people. Talking (and writing) about the excitements of research will help. So too will schemes such as those growing up between British universities and polytechnics with neighbouring groups of industries and schools. Although primarily intended to take the edge off recruitment problems, such devices may serve the broader purpose of demonstrating at first hand that research remains self-confident. But in the long run, what will matter more is that the research profession should be recognized as a successful one, either the matrix from which successful entrepreneurs spring or as one that enjoys the esteem of comparable professions, which means that among other things its members should be reasonably well-paid. There are some who remark regretfully that much of the government's extra £95 million this year will go on pay increases, but is that an unmitigated misfortune? Indeed, with the prospect of a true European Common Market no further away than 1992, should not the managers of the enterprise be planning to pay British scientists mainland salaries by then?

A further change that should not be forgotten is that worked by the pressures of the past decade on the temper of the grant-making agencies in Britain. The importance of the change is evident in the corporate plan (a name which is itself a pointer) of the Science and Engineering Research Council (SERC). Not so long ago, the council would have insisted in such a document that its function is to support research at universities; the range of laboratories it manages were all originally created to provide services (mostly equipment) that universities and polytechnics culd not manage on their own. But SERC tells how, "in association with HEIs" (presumably an acronym for Higher Education Institutions), it will "continue ... to support excellence in ... science and engineering". Its declared aim is that the ratio of resources spent on "strategic" and "basic" research will be in the ratio 60:40, identifying the former with "wealth-creation" and letting the reader guess that the latter has no economic significance, except perhaps in giving young people skills that may be put to economic use.

The shift of emphasis from the support of research institutions to the support of research itself is significant, and worrying. SERC's own spending on research grants has increased in the past few years commendably, but what has happened to the old notion that researchers, not committees, are the best (and most imaginative judges) of what might be done next? The distinction between strategic and basic research, like all attempts meaningfully to partition a spectrum by drawing a line across it, similarly makes no sense. As the whole world knows, it is not possible to tell with any certainty which research projects will create wealth and which will be largely academic in their consequences. But if there is some substantial parcel of British research which is certain to produce wealth, it would do so more even more effectively if it were market-orientated. In other words, SERC's policy is an invitation to some future government to complain that 60 per cent of what it does would be better hived off to industry. By insisting that these simple judgements of SERC's are heresy of a kind, the scientific community in Britain will not merely assure the integrity and thus safety of research, but may even help to save SERC from itself. □

Soviet nuclear dissent

Chernobyl is not the only reason why Soviet civil nuclear power is behind target. Can it pull back?

With the possible exception of the government of France, the Soviet government has so far been among the most resolute (and successful) in the pursuit of civil nuclear power. It is natural that the accident at Chernobyl should have given the nuclear planners pause, but that is not the only reason why 28 GW of planned capacity has been stripped from the original plans during the past year (see page 298). Even before the appointment of Mr Mikhail Gorbachev as Party general-secretary, there had been protests in republics as different as those in the south and the north-west at plans to build nuclear power stations there, often apparently as if to canalize more general discontent in directions that could not be held to be illegitimate. The coming of *glasnost* has inevitably complicated the planners' lives, creating for Soviet agencies problems to which they are unused — those of winning advance public approval for projects that, in the old days, would have been decided on strictly administrative grounds.

Now they are in a real fix. Members of the Soviet public have been given both a foundation (the Chernobyl accident, and the hair-raising evidence of mismanagement that it revealed) and a mechanism (*glasnost*, which is not merely a licence for the press, but for local and regional Soviets as well) for dissent. The result is that opposition to the nuclear power programme is no longer simply confined to what are called intellectuals, or to republic nationalists (the Lithuanian government last year declined to contribute, as required, towards the cost of a fourth reactor being built at a site on its territory), but is much more broadly based. Moreover, local and regional Soviets, whose consent is formally required for developments in their spheres of influence, can now speak up and have an incentive to do so. (Self-interest will have their members calculating that unpopularity with constituents may lead to defeat in some future popular election, if the electoral system does indeed develop along democratic lines.) Worse still, the nuclear planners find that the Soviet press has emerged into *glasnost* with a distinctly anti-nuclear predilection, born partly of Chernobyl and partly of the appearance of complacency among the managers. The result is that an article by somebody in high authority in a sufficiently august newspaper will no longer suffice to turn public opinion around. Nuclear planners in the West would find themselves on familiar ground in the Soviet Union now.

What is to be done? The Soviet target of 100 GW of nuclear generating capacity by the year 2010 looks unattainable. There are optimists who believe that 80 GW might be managed, but even that target must depend crucially on what happens in the next few years. Yet on traditional planning assumptions, nuclear generating capacity on some such scale will be needed if intended industrial developments are to succeed. Moreover, most of this extra power will be needed in the western regions of the Soviet Union, which happen also to be where most people live, and are now able to dissent. The assumptions on which the planners' forecasts are based may, of course, be incorrect, but in the absence of market pricing for different kinds of fuel, there is no way of being sure. Similarly, in the absence of direct incentives for users (as distinct from planners) to economize in the use of energy, the Soviet Union cannot easily expect that fuel efficiency will take the edge off the growth of electricity demand, as it has done in the West since 1973.

So there is no choice but to win round public opinion — a daunting task requiring that the Soviet nuclear industry should be even more adventurous in its exploitation of *glasnost* than even the most adventurous of the Moscow newspapers. Experience elsewhere (Britain, for example) shows that people must be told of routine mishaps at nuclear plants (as in industrial enterprises of all kinds) in the hope that they may eventually become familiar with the notion that the nuclear industry does not need to be literally free from accidents (but it has to be something of a paragon) to be safely manageable. It will be interesting, and may be instructive for the West, to see how brave the Soviet planners will be in these unfamiliar circumstances. But that they have little choice is beyond dispute. Meanwhile, in the search for nuclear generation sites, there seems little choice but to build new reactors at existing sites until the winds of dissent have abated. □

US budget pragmatism

The US budget problem is not its size, but how to cut it.

SENATOR Lloyd Benson's celebrated gibe at now-Vice-President Daniel Quayle, "You're no Jack Kennedy", might as well have been levelled at President George Bush last Friday, after his low-key inaugural address. But Bush is none the worse for that. Not every US president needs to sound like a Lincoln, a Roosevelt or a Kennedy, nor is rhetoric at the beginning of a four- or eight-year stint a guide to performance in the future. It may even help in present circumstances if the new presidency is seen to be manned by down-to-earthers who prefer to deal with real problems by solving them.

As yet, unfortunately, there are only straws in the wind as guides, and they seem to be blowing in contradictory directions. Everybody appreciates that US government support for research, like all its other discretionary expenditures, will be determined by the outcome of this year's tussle over the budget. As always, nobody will forget that this year's new congressmen (there are not many) will be campaigning for re-election before the next financial year (called fiscal 1990) is up. The best hope is that revenues can be modestly increased (preferably by natural growth, otherwise by devices that cannot this year be called taxes) and that expenditure can be selectively reduced. There are some signs of grace. The new National Security Adviser, the formidably phlegmatic General Brent Scowcroft, may have been less than enthusiastic about the Strategic Defense Initiative on television at the weekend: does that mean that a large part of $5,600 million, three times the budget of the National Science Foundation, has been saved already?

On the other side of the coin, there is a general air about the new administration suggesting scepticism of President Ronald Reagan's commitments to the arms control processes begun in the past six years. It is true, of course, that the new president is much less sceptical than was Reagan on entering office, and that it is natural that a new administration should turn a quizzical eye on the deals its predecessors have been making with others, if only to be sure of understanding them. It would not be the end of the world if the Bush administration should conclude, for example, that it would prefer to abandon the proposed 50 per cent reduction of strategic arms in favour of some other accommodation with the Soviet Union and its allies in the Warsaw pact.

Yet those in Washington now musing aloud that Mr Gorbachev is interested in arms control and other accommodations only because of his domestic economic problems (and Gorbachev appears to admit that his budget is part of his motive) should reflect that the same calculation could apply to the United States. The most inflexible part of the US budget is that (nearly a third) spent by the Pentagon. The years immediately ahead will be especially difficult because development projects will be clamouring for procurement. Would it not be a prize worth having to be able to cut the defence budget without endangering security? The new administration is only a few days old, and there are many urgent matters clamouring for attention, but it will be a misfortune of this trade-off has not arisen naturally before the budget negotiations reach their climax later in the year. □

Sakharov defeated by "odd arithmetic"

- Absentees assumed to vote against
- Academy relinquishes five seats
- Sakharov nominated for Moscow City

Moscow

THE failure last week of the enlarged plenum of the Soviet Academy of Sciences to nominate Andrei Sakharov for the forthcoming election of Soviet deputies has caused great surprise and raises the question whether Soviet people, including men and women of science, yet know enough about democracy to practise it.

Sakharov, who had been supported by 60 of the academy's institutes, was not the only disappointed candidate. There were also Roald Sagdeev (supported by more than 25 institutes), Dmitri Likhachev (20 institutes) and such prominent economists (active advocates of *perestroika*) as Gavriil Popov (15 institutes plus), Nikolai Shmelev (more than 12), Gennadi Lisichkin and Abel Aganbegyan.

Last week's proceedings were an intermediate stage in the election of the 2,250 members of the Congress of People's Deputies, which will meet once a year to decide constitutional matters and will also elect the bi-cameral Supreme Soviet. A total of 75 seats in the chamber has been reserved for representatives of professional associations and societies, of which the academy had 25. But scientists can be elected by other categories of voters. Thus Guri Marchuk, president of the academy, and Yevgeni Velikhov, vice-president, have been nominated as candidates by the Communist Party.

The 17-member electoral commission took two hours to determine the outcome of the voting, by secret ballot. When the results were announced 10 hours after the meeting had begun, those left on the platform and in the hall were equally surprised. The outcome was so unexpected that it seemed like the dénouement of a whodunit.

One strange consequence is that there are now fewer contenders (23) than there were originally vacancies (25) in the academy's intended representation in the Congress of People's Deputies. It had been planned that there would be a meeting in two months at which the contenders would compete, promoting their own platforms. But the first outcome of the plenum would have made meaningless the continuation of the election of the academy's list: the contenders would have had no rivals.

Accordingly, the members of the plenum decided to cut the academy's representation first by two and then by five, a decision endorsed by the praesidium (governing council). The spare seats will be filled by other academic societies and associations.

This development points both to the imperfections of the electoral machinery and to the likelihood that people do not fully appreciate their role in the democratic process.

This election is in two stages. In the first, nominations were made by the members of academy institutes and establishments. People at these meetings participated enthusiastically. Eventually there were more than 130 names on the list of those seeking the academy's nomination. Last week's plenum was intended to prune the list for a second stage at which choices would be made by all members of the academy and institute representatives (one for every 150 workers).

By prior agreement, the plenum did not discuss all the candidates because of lack of time. But it was agreed that the opinions of nominating institutes should be studied carefully, which is significant because the plenum thereby learned of the nominees' scientific and, more importantly, civic qualities. But the outcome of the plenum's procedural discussion was also to ensure a vote 'against' from each of its absent members.

Strictly, this accords with Soviet electoral law, which requires that those elected should receive "the vote of more than half the aggregate number" of those entitled to vote. Last week, 379 people were eligible to attend the enlarged plenum, but 102 of them were absent for various reasons. Whether the academy's election commission ever discussed with the central electoral commission the question of how the absent votes should be dealt with is unknown.

In the event, the qualifying quota was set at 139 votes, but only 190 people took part in the voting, so that the votes of the 89 people who did not were counted as 'against' in each case. Thus each contender had to secure 73 per cent of the votes to be elected. (Yablokov needed only one extra vote, but Sagdeev needed 18 and Sakharov 34.)

Much the same happened at the All-Union Society of Inventors and Innovators, where the same odd arithmetic meant that only six contenders instead of ten managed to secure qualifying votes. But that council reconvened the plenum to fill the 'vacancies'. Should not the academy have done the same?

One interpretation of the purpose of the academy's plenum is that it was to ensure that the final choice of its 25 representatives would be genuinely competitive, reflecting the will of the scientific community at large. This might reasonably have been done in keeping with certain criteria, such as the number of institutes backing each candidate.

Many of those not nominated had solid backing. It goes without saying that Sakharov was the undisputed leader in the race he eventually lost. But Sakharov is extremely popular outside as well as within the scientific community, with the result that he was nominated, at a meeting on 20 January at the Lebedev Institute where he works, as a candidate for people's deputy from Moscow's Octyabrsky district and, two days later, as a candidate in the election of a deputy to represent the City of Moscow. **Yuri Kanin**

Novosti

Tajikstan struck by earthquake

London

THIS week's earthquake in the Soviet republic of Tajikstan, although not as serious as the Armenian catastrophe last month, has inevitably added to growing concern in Tajikstan about seismic safety.

The earthquake is the third in four years. There was a major earthquake in the north of the republic in October 1985 and the collapse of a dam at Sargazan in March 1987. Land and mudslides, such as that which this week buried two villages, are a common accompaniment.

What concerns the population most is the rapid development of hydroelectricity in the republic. A further eight dams are now planned on the River Vaksh, which already has the massive Nurek (305 m) and Rogun (345 m) dams. People fear that earthquakes may rupture the dams, and even that the dams themselves may trigger earthquakes.

At a meeting two years ago in the Tajikstan capital of Dushanbe, representatives of the Tajikstan Academy of Sciences revealed that the dams had been designed for seismic conditions appropriate to a plain, not a mountainous region, where the effects of seismic disturbances are usually greater. *Pravda* described the new Ziddin reservoir as "millions of cubic metres of water hanging like the sword of Damocles" over Dushanbe.

Tajiks themselves, who say they have little need of the electricity which is mostly exported to Afghanistan and other republics, seem in little doubt. A few days after the Spitak disaster, environmentalists and others formally petitioned for a halt to dam construction. **Vera Rich**

NIH gives the go-ahead on genetic experiment

The controversial first experiment to involve the insertion of foreign genes into humans — which has been deliberated by seven US review committees and government agencies over the past several months — received approval to proceed last week. James Wyngaarden, director of the US National Institutes of Health (NIH), authorized Steven A. Rosenberg and W. French Anderson to readminister interleukin-2-stimulated T-lymphocytes marked with a gene for neomycin resistance to ten cancer patients from whom the cells were isolated. The inserted gene will provide no therapeutic benefit to the patients, but will enable Rosenberg and Anderson to determine if the cells return to the tumour to fight the cancer. C.E.

Vet schools to close

The University Grants Committee announced last week that two of Britain's six veterinary schools are to close. A working party appointed to consider the rationalization of veterinary education said that no school is at present able to teach clinical science with the necessary spread of disciplines and depth of coverage.

The schools at the Universities of Glasgow and Edinburgh will be merged to form a new school based in Edinburgh, and veterinary deg-rees will no longer be obtainable at the University of Cambridge. The last intake of students will be for the academic year 1989–90. The remaining schools, at the Universities of Bristol, Liverpool, London and Edinburgh, will have no fewer than 36 senior clinical teachers and will teach about 76 students each year. C. McG.

Scientists for Phobos

Ten US scientists, including Bruce Murray of the California Institute of Technology and Thomas Duxbury of the Jet Propulsion Laboratory, have been selected to participate in the Soviet Phobos mission, due to reach Mars and its satellite by April this year. The ten were chosen jointly by the National Aeronautics and Space Administration (NASA) and Soviet delegations to a US – Soviet working group — the working group was set up under the 1987 cooperative agreement on space research between the two countries.

Meanwhile a new agreement to foster scientific cooperation was signed in Paris earlier this month by outgoing US Secretary of State George Schultz and Soviet Foreign Minister Eduard Shevardnadze. In eight general areas, including science policy and problems of the Arctic as well as all the traditional disciplines, US agencies and their Soviet counterparts will draw up plans to facilitate cooperative research. D. L.

More criticism for NIH over 'summary' cut of grants

Boston

THE US National Institutes of Health (NIH) are drawing more fire for their decision to end financial support for two scientists accused of misconduct before an investigation into their case had been completed.

NIH procedures for investigating misconduct have recently come under heavy criticism. The current case involves two scientists at the Harvard-affiliated Massachusetts Eye and Ear Infirmary. Kenneth Kenyon and Scheffer Tseng (Tseng is now a researcher at the University of Miami) are alleged to have had business interests in an ophthalmic ointment they were testing with funds from NIH and to have delayed publication of results showing the ointment to be ineffective (see *Nature* **336**, 506; 8 December 1988). NIH suspended their research grants late last year, but are still investigating the affair.

But Claes Dohlman, outgoing chair of the ophthalmology department, this week sent a letter to NIH officials expressing his concern over the agency's action and protesting at what he calls the "summary way" in which NIH reached their decision. Dohlman's letter follows a similar one earlier this month from Charles Schepens and Richard Pharo, respectively president and director of research administration at the Eye Research Institute in Boston.

"To take action in the absence of evidence is unjustifiable", write Schepens and Pharo, adding that NIH's move sends a message to the medical research community that "the federal government is prepared to abandon a scientist without due process". Last month, Representative John Dingell (Democrat, Michigan), chairman of the House of Representatives Energy and Commerce Committee oversight and investigations subcommittee, which has been holding hearings on how scientific misconduct charges are investigated, wrote to Otis Bowen, the Health and Human Services Secretary, with similar complaints about the way the case was handled (see *Nature* **336**, 706; 22 December 1988). Dingell, in a sharply worded letter, accused NIH of reaching their decision solely on the basis of newspaper reports and called upon NIH officials to explain the rationale and precedent for their decision.

In a letter responding to Dingell's concerns, Robert Windom, Assistant Secretary for Health of the Department of Health and Human Services, writes that NIH "acted responsibly" on the basis of the information they had at the time, which he states was "sufficient to demonstrate a clear, urgent need for interim administrative action". Windom claims that, in addition to newspaper accounts, the agency based its decision to terminate Kenyon's and Tseng's financial support upon conversations with Harvard officials and upon a statement written to the Harvard faculty about the case by Daniel C. Tosteson, dean of Harvard Medical School. Jack McLaughlin, associate director of the National Eye Institute of NIH, did acknowledge, however, that the agency first learned about the case through newspaper accounts.

Both Windom and McLaughlin assert that there are precedents for NIH's move, although neither points to any specific case. McLaughlin stresses the importance of treating such incidents on "a case-by-case basis", and says only that he is sure that similar "interim actions" have been taken in other cases at NIH.

A staff member on Dingell's subcommittee has called NIH's response "disingenuous" and "inconsistent" with the subcommittee's records of what transpired in NIH's decision. Hearings on the matter by Dingell's subcommittee are expected to begin in early March, and reports are due before that from at least one of NIH's investigations. **Seth Shulman**

Vice-chancellors' pay offer to staff rejected

London

UK university management last week tried temporarily to resolve the pay dispute with staff by offering to increase salaries by 3 per cent from April 1989 and make a lump sum payment at that time equal to a 3 per cent rise for the period from 1 January to 31 March 1989.

After making the offer, the Committee of Vice-Chancellors and Principals acknowledged that it was too low. Sir Mark Richmond, chairman of the committee, said it was embarrassed at the inadequacy of the offer. There was a desperate need to pay academic staff decent salaries, but the committee thought staff would rather be assured of something now while it continued to argue for more. The vice-chancellors are to approach the government for extra money for 1989–90 which would be used by individual universities to reward merit and make discretionary payments to teachers in subjects short of staff.

The Association of University Teachers rejected the offer and will continue its boycott of university examinations. But it was cheered by the vice-chancellors' offer to backdate the offer to cover part of 1988–89. Christine McGourty

Guidelines produced for the use of transgenic animals in research

London

With transgenic animals finding increasing favour in both biomedical research and biotechnology, the UK Advisory Committee on Genetic Manipulation (ACGM) has produced detailed guidelines on their use. The guidelines, which the committee hopes will set an example for other countries, are particularly concerned with the consequences of the deliberate or accidental release of transgenic animals into the wild, and the hazards of using viral, and especially retroviral, vectors for transgenes — that is, the use of genetically modified viruses to introduce new genes into animals.

ACGM, which will need advance notification of any plans to use viral vectors or to release transgenic animals, warns that it will be tough on both. For animals that are to be released, there will be a ban on the use of any viral vector that contains even a partially functional oncogene and on any form of vector that has even a remote potential to replicate. Plans to use equivalent vectors to produce contained transgenic animals will be considered individually.

Among the considerations will be the precautions that have been planned to ensure containment. For large animals, ACGM takes the view that a well-fenced field is sufficient. Extra care will be needed for fish and other aquatic vertebrates because of the relative ease with which they or their gametes can escape. Even greater precautions are necessary for work with invertebrates that "crawl, jump or fly".

Some of the guidelines on genetic manipulation anticipate changes in the official Health and Safety Regulations, which were drawn up in 1978. Revised regulations suggested by the Health and Safety Commission in October 1987 have since been modified, and now await approval by the Secretary of State and parliament. Their main intent is to establish a legally backed compulsion both to notify ACGM of the production and use of transgenic animals and to set up and operate local risk assessment committees at any establishment that carries out genetic manipulation.

ACGM's guidelines also cover aspects of work with transgenic animals that fall outside its own purview. The welfare of such animals is "dealt with adequately by existing legislation", the guidelines say, pointing out that breeding from transgenic animals is regulated as though an animal experiment until it can be demonstrated that the progeny are not likely to suffer any adverse effects.

The guidelines advise that the consumption of transgenic animals or their products by humans or animals would be subject to consideration by the Advisory Committee on Novel Foods and Processes, which may in turn seek advice from ACGM. Professor Mark Williamson, who chaired the working group that drew up the new guidelines, says it is inconceivable that approval would be given to the consumption of animals containing a human transgene. **Peter Newmark**

HIV a problem for Indian blood banks

New Delhi

India is suffering from a wave of public alarm caused by news that human immunodeficiency virus (HIV) is increasingly being transmitted by use of donated blood. This development conflicts with the earlier belief that AIDS is being spread chiefly by prostitutes and foreigners.

Officials say that the government can no longer postpone compulsory screening of all blood banks, a suggestion that only six months ago was dismissed as unnecessary as well as impracticable.

No transfusion-related HIV infection had been detected in India until July 1987, which is one reason the government was content with only minimal restrictions on imported blood products. But since then, the proportion of seropositive cases ascribed to transfusion has been increasing rapidly.

Last month alone, the All-India Institute of Medical Sciences in New Delhi discovered antibodies to HIV in three haemophiliac patients, and doctors in another hospital said that 10 of their 6,136 voluntary blood donors tested positive for AIDS. Of the 620 confirmed cases of HIV infection in India, about 60 have received blood transfusions in Indian hospitals.

According to the Indian Council of Medical Research (ICMR), which operates some 40 AIDS surveillance centres, blood transfusion has become an important mode of HIV transmission. An estimated 1.5 million units of blood are used each year in India, but ICMR's centres can perform only 30,000 tests, using kits imported from Britain. Complete blood screening would require a 100-fold increase in the number of kits. Although ICMR feels that all donated blood must be screened, the job "cannot be done overnight".

As a first step, all donors in Bombay and Madras are now being screened, and experience from these cities will be used to start screening in other cities in about a year, by which time India hopes to be producing its own test kit. K.S. Jayaraman

Italian environmental programme launched

Turin

The Italian government last week launched a £70 million programme of research into environmentally benign technology. Research priorities must be formulated within two months by a new commission which will report to the ministries for industry and for the environment which are financing the programme.

The announcement was well-timed, coinciding with an international conference in Turin designed to increase public awareness of the problems of the greenhouse effect, the destruction of the ozone layer and acid rain and to stimulate political action to tackle these problems. Among the recommendations of the conference was a proposal to impose a tax on fossil fuels which would finance a world fund to promote alternative energies and energy efficiency. The conference also recommended improved monitoring of climate change and increasing research into an understanding of the problems. The Italian government was heavily criticized for the lack of support for such research. Money is scarce and research uncoordinated, as well as being hindered by a lack of access to meteorological data, which is controlled by the defence ministry. Christine McGourty

Testing of *in vitro* embryos approved

Melbourne

An Australian parliamentary committee has approved a controversial request by scientists at the Monash Medical Centre in Melbourne to test human embryos obtained for *in vitro* fertilization (IVF) for birth defects before implanting them in patients.

Tests will be done about two days after fertilization, when the embryo has grown to four cells. One cell will be removed and analysed for genetic defects. The tests will be performed only on embryos that take longer than usual to fertilize. According to Monash Medical Centre's Professor Carl Wood, the Australian pioneer of IVF, about 3 per cent of embryos have a delayed fertilization, but are not neccessarily abnormal. The tests will prevent normal embryos from being discarded. Embryo biopsy does not seem to damage the survival chances of the remaining embryo.

The decision of the committee, chaired by Professor Louis Waller of Monash University, may cause problems for Victoria Health Minister David White, who has written publicly that there will be no experimentation on human embryos older than 22 hours. The scheme may also face legal problems, as it involves the use of fertilized embryos but is not directly related to alleviating infertility. Tania Ewing

UK research grants suffer from SERC's lack of money

London

FIGURES published this week in the Science and Engineering Research Council's corporate plan highlight the growing imbalance in supply and demand for UK research grants. Expenditure has increased slightly since the first plan was published in 1984–85, but costs have increased further and the council cannot support the increasing number of grant applications. The research grant success rate for alpha-rated proposals decreased from 72 per cent to 48 per cent in science and from 98 per cent to 86 per cent in engineering. For standard grants, the success rate decreased from 28 per cent to 20 per cent in science and 39 per cent to 32 per cent in engineering. The council hopes to increase the percentage of grant-in-aid spent on research grants from 33 per cent in 1987–88 to 40 per cent, and to maintain at a constant level the numbers of research assistants supported by its grants.

Expenditure on equipment must increase, and the council hopes to achieve this by increasing the proportion of grant money that supports equipment and by allocating for equipment money for the interdisciplinary research centres (IRCs). Five IRCs have been established and the council plans for another 17 by 1991. More than 300 applications to host the centres have been received. But the plans for expansion depend on the money available. Only 50 per cent of the cost can be met from existing funds, says the council. It will seek further money from the research council's flexibility fund and from the Department of Education and Science.

The council plans to continue increasing the proportion of its budget devoted to strategic research with the aim of achieving a 60:40 ratio between support for strategic and for basic research by 1990–91. In the past decade, support for strategic research has increased from 42 per cent of total expenditure in 1978–79 to 54 per cent in 1987–88. For basic research, the council would like to make the support mechanism more long-term and to link expenditure to the country's gross domestic product.

Other council plans include an increase in expenditure on the LINK programmes, which are supported jointly by the research councils, government departments and industry. It plans to initiate eight more programmes annually over the next three years and to increase annual expenditure to £20 million in five years.

The council is also planning a collaborative programme of atmospheric research with the Natural Environment Research Council, to integrate satellite, ocean, Earth and atmosphere measurements with gas-reaction kinetic data and with related computer simulations.

Expenditure on space science will not be increased and, so that it might in future select parts of the science programme of the European Space agency in which to get involved, the council urges a review of ESA's method of operation to include some optional elements.

Soviet bloc research criticized

London

COMECON'S Comprehensive Programme of Scientific and Technological Cooperation, the first major policy development of the Gorbachev era, has been roundly criticized on Prague radio. Comecon, the trade and development alliance of the Soviet bloc, is celebrating its fortieth anniversary this week.

The programme was intended, when launched in December 1985, to encourage joint enterprises between member countries and was regarded as a step towards decentralization. Previous policy had been heavily orientated towards the Soviet Union, with a Soviet "head" institute for every project. The best-known exception had been the low-temperature magnetism laboratory at Wroclaw in Poland.

Radio Prague commentator Vladimir Vercak now says that within a few months of the adoption of the new programme, it was clear that differences of economic management in member countries would prevent the goals of the programme being attained. Joint enterprises have been successfully established only where long-standing partnerships already existed, but the lack of an intra-bloc currency is also an impediment. Unless the economic conditions of member states are rapidly improved, he concludes, the programme will not realize "Comecon's scientific and technological potential".

A NATO conference last autumn showed that there may be other problems. Speakers with first-hand knowledge of bloc countries drew attention to the way that the lack of equipment and resources tempts scientists and engineers to seek collaboration outside the bloc, while enterprises are often more interested in preserving their chances in world markets than in the needs of its socialist partners.

Most French pupils to go to university

Paris

A major overhaul of the French education system published last week by Education Minister Lionel Jospin aims to make France the best-educated nation in Europe by the year 2000. The plans, estimated to cost between $8,000 million and $160,000 million, include massive recruitment of teachers, better teacher training and a revised curriculum. The goal is that 80 per cent of school-leavers should be able to go to university, while the rest should not leave school without a diploma in business or industrial skills.

Education and research were priorities in President François Mitterrand's pre-electoral "letter to the nation" last spring. Despite a national curriculum, with 90 per cent of pupils attending state schools, only 40 per cent get the chance of a university education. Every year, 100,000 pupils leave school without any qualifications. Over one third of school leavers who do obtain their *'bac'* (university entrance certificate) and go on to university fail to complete their course, many dropping out after the first year having failed the stiff examinations.

Jospin says that schools have an unwritten contract with children and their parents to provide the education they desire. One necessary step needed to fulfil this contract is to reduce class sizes. To this end, 300,000 new teachers are to be recruited over the next ten years. To make the profession more attractive, money will be provided to close the gap between the university-oriented 'lycées', and the less specialized, but also lower status, 'colleges', which are understaffed and have a high failure rate at the *baccalaureat*. Teacher-training institutes are to be set up and secondments introduced to allow teachers to improve their career prospects, as well as to catch up in their subjects.

The two main concerns with Jospin's plans are that success rates will be made artificially high by lowering pass marks, and that already overcrowded and crumbling universities could not cope with a large influx of students. Despite these objections, and some resistance from lycée teachers, the reforms have met with general approval.
